CAPVT I. De Opere Primi Diei, ſeu de Creatione Cæli & Terræ Luciſq. ac Temporis ex ſacra Geneſi,& ad mentem Patrum ac Theologorum.

Chapter 1. On the Work of the First Day, that is, on the Creation of Heaven and Earth, of Light and of Time, from holy Genesis and according to the mind of the Fathers and Theologians.

I. It is surely right to prefer Moses to Plato and Aristotle, so that in searching out the foundations of this world we may be lit rather by that twin horn of divine light with which, from the face of the Lord, the countenance of that same Moses shone, than by the half-extinguished spark of profane philosophy. Yet, so that everyone may be equally satisfied, we must select from both lights those things that bear more closely on astronomy, deliberately passing over many things the knowledge of which matters almost nothing to us, at least for the purpose of the work we have undertaken. Of this kind are: whether there is a single world, or whether there now are, or once were, or will be several or infinitely many worlds; whether it was made in the beginning of time, as the Catholic faith teaches, or existed from eternity, as the Peripatetic school foolishly proclaims; whether it is perfect in every respect, or further perfectible; whether it was created or produced by God alone immediately, or through Intelligences subordinate to Him; whether this whole universal machine rests in some determinate part of the divine Immensity, or in some imaginary space, as they call it, or rather, without our knowing it, rolls on perpetually through that immensity as a whole; why this world was founded in this virtual part, so to speak, of the divine eternity rather than in another; and other questions like these, partly inscrutable, partly altogether foreign to the bounds of astronomy. For none of them can be discerned from the phenomena of the heavens, nor is it useful for explaining those phenomena. Passing over these, then, we shall turn [?] our thought and our pen to other matters suited to our purpose, first setting out some things that will seem more necessary for these very matters. [Margin: Controversies about the world that do not concern the astronomer.]

Question 1. *Whether by those words, "In the beginning God created Heaven and Earth, but the Earth was empty and void", the creation of any determinate body made on the first day is signified.* [Margin: Genesis 1.]

II. There is no doubt that by the names of Heaven and Earth the entirety of this whole universe is signified sometimes. That is how we must understand the saying of Genesis 2, *In the day that God made Heaven and Earth*; that of Exodus 31, *In six days God made Heaven and Earth*; that of Jeremiah 23, *I fill Heaven and Earth*; and finally that of the Apostles' Creed, *I believe in God, Creator of Heaven and Earth*. In this sense, then, some hold that Moses said that Heaven and Earth — that is, the universal world — were created in the beginning, not because the whole was created in the first moment of the first day, but because Moses set out in summary the argument of the divine works that were to be created successively thereafter. On this view he signified by these words nothing determinate made before the light, but set out only the aggregate of the things he was afterwards going to narrate as made in six days — just as if someone were to say: what God made in the first six days are Heaven and Earth. This interpretation is reported, though with hesitation, by St Augustine, *Confessions* book 12 chapter 17, and *De Genesi contra Manichaeos* book 2; and by St Cyril of Alexandria, *Contra Iulianum* book 2, in these words: *That, embracing everything comprehensively and as on a small tablet, he narrates the birth of the whole of nature.* St Thomas Aquinas, part 1, question 68, article 3, attributes the same view to St Chrysostom; Steuchus [Agostino Steuco] defends it in his *Cosmopoeia*; and so does Paulus Burgensis [Pablo de Santa María], addition 1, he too attributing it to Chrysostom.

But rightly, and following the more common teaching of the Fathers, *Ascanius Martinengus* [Ascanio Martinengo] in the *Glossa magna* p. 162, *Pererius* [Benito Pereira], *In Genesim* book 1 p. 26, *Suarez*, *De opere sex dierum* book 1 chapter 3, and *Tannerus*, *Summa theologica* vol. 1, disputation 6, question 2, doubt 1, teach that these words signify something determinate and actual, created by God in the beginning of the first day, that is, in the first instant of all time, before light was made. For by the particle *autem*, which is copulative, there is added at once: *But the Earth was empty and void, and darkness was upon the face of the deep, and the Spirit of the Lord was borne over the waters.* It is therefore supposed that the Earth had been made, but empty and void, and the deep and the waters — whether this was Chaos or something else, of which more shortly; and this is perhaps what Saints Cyril and Chrysostom meant to indicate. Keeping to the letter, then, we can accept neither the view of Plato — who, as St Justin noted in his *Admonitorium*, took his doctrine of the Ideas from these words of Moses — nor that of Philo, who says in *De mundi opificio* that before all things God made the ideas of heaven and earth in the intelligible world. For Moses did not set before an unlettered people ideas scarcely intelligible to the learned; nor are the divine Ideas separate from God, if they are taken formally and not objectively, nor are they something created or made. Rather, they are connatural with God from eternity and identical with Him, as St Thomas teaches, part 1, question 15, with St Augustine and most theologians. [Margin: Whether the Ideas of Heaven and Earth.]

Quæſtio 2. De notione nominis Cæli ac Firmamenti apud Latinos & Hebræos.

Question 2. On the meaning of the names Heaven and Firmament among the Latins and the Hebrews.

III. As for the meaning of the name: heaven is called οὐρανὸς [Greek: ouranos, "heaven"] in Greek because it is seen above, for ὁράω [Greek: horaō] is "to see" and ἄνω [Greek: anō] is "above". What if it comes from the Hebrew word *Or*, of which I shall speak in chapter 4, number 9? In Latin, *caelum* is so called because it conceals [celat] the air; or because, as Philo says in *De mundi opificio*, it is the ὥρος [recte: ὅρος] [Greek: horos, "boundary"], that is, the boundary, of all things; or because it was the first of the ὁρατῶν [Greek: horatōn], that is, of visible things, to be made; *or from its loftiness, or from engraving* [caelatura], as Bede says in his exposition of Genesis chapter 1; or because it conceals the higher things, or is, as it were, an engraved vessel, picked out with stars as with figures in relief, as St Isidore thinks, *Etymologies* book 13 chapter 10, and before him Varro, *De lingua Latina* book 5, and St Ambrose, *Hexaemeron* book 2 chapter 4. Or else because it conceals, that is, covers, all sensible things, as Petrus Comestor says, *Historia scholastica* chapter 4, together with *Abulensis* [Alonso Tostado] and *Hugo Carensis* [Hugues de Saint-Cher]. Varro, however, also thought that *caelum* was named from the Greek word κοιλὸν [Greek: koilon], which means "hollowed out"; for to us it appears hollowed out, or concave. [Margin: Etymology of heaven.]

But in this place the Hebrew reading has *Ha-samaim*, or *Haxamaim*, that is, those bodies worthy of stupor and wonder, from *Samah*, which means, among other things, to wonder and to be astounded; just as in Isaiah 53 the phrase *Many were astounded over you* is expressed in Hebrew by the verb *Samemù*. But if it is derived from the root *Sem*, which means "name", the name *Samaim* will signify the most named and most famous bodies. For the Hebrews too call famous men "men of name", that is, renowned men, which our Vulgate renders in Genesis 6: *These are the mighty ones of old, famous men.* [Margin: What is Samaim in Hebrew?]

Lusitanus, Martinengus and our Fernandius, on Genesis chapter 1, accept both interpretations; although Lippomanus [Luigi Lippomano] in his *Catena* interprets *Samain* as "there water", and Suarez, *De opere sex dierum* book 1 chapter 7, as simply all diaphanous bodies [?]. And although among the Hebrews this noun lacks a singular, and could have been rendered *He created the heavens*, the Chaldean version, that of the Seventy Interpreters, St Jerome and our translator nevertheless rightly render it in the singular. They do so either because a single heaven was created on the first day; or because it was created without the distinction of stars and motions, and with these set aside we have no sensible difference between heavens; or because, just as Moses wished to include all the elements under the name of the one Earth, so he wished to include the orbs of all the heavens under the name of the one heaven.

Finally, it must be noted, following Lusitanus and Martinengus, that in this place of Genesis the particle *He* or *Ha* is placed before *Samaim*; joined to a noun, it makes its meaning distinguished. So *Hasamaim*, as I said, denotes those distinguished and stupendous, or most renowned, bodies. In the same way, if you put *He* before the noun *Nabi*, which means "prophet", saying *Hanabì*, it will signify "that Prophet", that is, the distinguished one. This particle, as Fernandius says, when added also to the noun *Eres* or *Erez*, makes *Haarez*, which signifies that Earth, dry as well as fluid, or habitable as well as uninhabitable, as Lusitanus notes. Its root, however, is *Rus*, which means to rush and to run, as a heap of sand does; and so the earth, separated from its admixture with water, was called by God *Arida* [the dry land], Genesis 1 — or from *eruendo* [digging out], as I shall say more fully in question 3, towards the end of number 10. The name *Firmament*, further, will be explained far more suitably below, in chapter 2, number 2. [Margin: What is Hasamaim?] [Margin: What is Eres in Hebrew?]

Quæſtio 3. Quid Nomine Cæli ac Terræ Moyſes ſignificauerit creatum à Deo in prinmo inſtanti Mundi ?

Question 3. What Moses meant by the name of Heaven and Earth as created by God in the first [?] instant of the world.

IV. It is incredible in how many and how different ways the Fathers and Doctors of the Church have understood those two names, Heaven and Earth, with which Moses began to narrate the first creation of things, as may be seen in the authors who wrote books of *Hexaemeron* — that is, on the works of the six days — or glosses or postils, or commentaries, or questions on Genesis chapter 1. Many report their words, but Ascanius Martinengus most diligently of all, in his *Glossa Magna*; and we shall bring forward some selected ones below, from number 9 onwards and in questions 4, 5 and 6, where we judge that greater proof is needed. In this question, so as not to be too prolix on account of the many interpretations, it will be enough to indicate the places where the authors' words can be sought.

First, then, St Justin attests in his *Admonitorium* that Plato understood by those names the Ideas of Heaven and Earth, when he read them in Genesis and compared them with the words of Exodus 25 and 26, in which the pattern of the Tabernacle was shown to Moses by God on the mountain. [Margin: 1st interpretation.] Second, others understood formless matter, out of which Heaven and Earth could come to be, or which was Heaven and Earth in potency, not in act. So St Augustine, *De Genesi contra Manichaeos* book 1 chapter 7, *De Genesi ad literam imperfectus* chapter 3, *De Genesi ad literam* book 1 chapter 14, and *Confessions* book 12 chapter 20; St Gregory of Nyssa in his *Hexaemeron*; Hugo Carentis in his postils; and Alcuin, question 28 on Genesis. But St Augustine, in that chapter 14, holds that matter to be prior to the actual forms in origin, not in time, as I shall teach in question 5. [Margin: 2nd interpretation.] Third, some understood by the name of heaven and earth the formless matter not only of bodily but also of spiritual things. So St Augustine,

De Genesi ad literam book 1 chapter 1; Origen, homily 1 on Genesis; Bede on chapter 1 and in his *Questions on Genesis*; Strabus [Walafrid Strabo] in the *Glossa ordinaria*; Eucherius, *Commentary on Genesis* book 1 chapter 1; the Master, on book 2 of the *Sentences*, distinction 12; Hugo Victorinus [Hugh of Saint Victor], *De sacramentis* book 1 part 1 chapter 1; and also Hugo Carensis in his postils. [Margin: 3rd interpretation.]

Fourth, that by the name of Heaven the invisible created nature or substance — that is, the spiritual and intelligible — can be understood, and by the name of Earth the visible, bodily and sensible nature, was taught by St Augustine, *De Ge-* [Margin: 4th interpretation.]

nesi ad literam book 1 chapter 1, and in the unfinished work, chapter 3, and *De Civitate Dei* book 11 chapter 33; St Ambrose, *De Abraham* book 2 chapter 8; and Anselmus Laudunensis [Anselm of Laon] in the *Glossa interlinearis*.

Fifth, some, as though explaining the preceding interpretation, understood by the name of Heaven the angels, perfect naturally or supernaturally, and by the name of Earth bodily matter, as being imperfect. So St Augustine, *De Genesi ad literam* book 1 chapter 1; Albertus Magnus, part 1 of the *Summa de quattuor coaevis* [On the Four Coevals], question 2, article 9; Strabus in the *Glossa ordinaria*; and St Gregory the Great in his commentaries on Ezekiel and on Job, book 27, chapter 25. But St Augustine understands angels already blessed, whereas St Gregory understands them as not yet blessed; for afterwards he understands them under the name of the Firmament, when they were confirmed in grace and beatitude. [Margin: 5th interpretation.]

Sixth, some thought that under the name of Heaven the Empyrean together with the angels is comprehended, and under that of Earth the matter of the elements under one common form of corporeity, or the elements undistinguished. So St Bonaventure, on book 2, distinction 12; Lyranus [Nicolas de Lyre] in his postils; and Tostatus [Alonso Tostado] on Genesis chapter 1, who attribute the same view to Strabo and Bede; and Ambrosius Catherinus [Ambrogio Catarino Politi] in his exposition of Genesis chapter 1. [Margin: 6th interpretation.]

Seventh, some understood by the name of Heaven the Empyrean indeed, together with the angels, but by the name of Earth the elements constituted in act under their own forms, though confused. So Iunilius in his *Hexaemeron*; Hugo Victorinus in the *Sentences*, treatise 2 chapter 1; Rupertus Abbas [Rupert of Deutz], *Commentary on Genesis* book 1 chapter 6; Gulielmus Parisiensis [Guillaume d'Auvergne], *De Universo* part 1, from chapter 31 to 40; Alexander of Hales, *Summa* part 2, question 45, member 2; Comestor at the beginning of the *Historia*; Strabus in the *Glossa ordinaria*; our Molina [Luis de Molina], *De opere sex dierum*, disputation 2; Salianus [Jacques Salian] in the *Apparatus* to the *Annales*, chapters 6 and 11; and our Fernandius on Genesis chapter 1, section 2. But Hugo Victor understands the four elements as undistinguished and extending all the way up to the Empyrean in that beginning of the world; Iunilius, by contrast, the 4 elements arranged so that air and fire were inside the earth; Comestor, the 4 elements, saying nothing of their order. Rupertus,

Parisiensis, Halensis, Molina, Salianus and Fernandius, however, understand only two elements, Earth and Water. [Margin: 7th interpretation.]

Eighth, some understood the angels by the name of Heaven, and by the name of earth the elements in act, confused into one Chaos; the Master, on book 2 of the *Sentences*, distinction 12, mentions these without rejecting them. [Margin: 8th opinion.] Ninth, some included under the name of Heaven all the heavens with the angels, or all higher things, and under the name of Earth all lower and palpable things. So St Augustine, *De Genesi ad literam imperfectus* chapter 3; Anastasius Synaita [Anastasios Sinaites], *Commentary on the Hexaemeron* book 1; Petrus Riga [Pierre Riga] in the *Mundi Aurora*; and Petrus Comestor in the *Historia Scholastica*, on Genesis chapter 1. [Margin: 9th interpretation.]

Tenth, Gennadius, Acacius and Caietanus on Genesis chapter 1, and Hamerus and Lyranus in the same place, hold that under the name of Heaven all the heavens with the angels can be understood, and under the name of Earth the elements in act with their forms. [Margin: 10th interpretation.] Eleventh, Lippomanus in his *Catena* on Genesis supposes that by the name of Heaven the Empyrean and all the heavens with the angels — indeed fire and air as well — can be understood, and by the name of earth the Earth and water. [Margin: 11th interpretation.]

Twelfth, Albertus Magnus, part 1 of the *Summa de quattuor coaevis*, question 12, article 9, hints that by the name of heaven either the Empyrean alone or all the heavens can be taken, and by the name of earth formless matter or the elements. [Margin: 12th interpretation.] Thirteenth, Saints Basil, homily 1 on the *Hexaemeron*, Ambrose, *Hexaemeron* book 1 chapter 6, and Damascene, *De Fide* book 2, chapters 5, 6 and 10, teach that by the name of heaven the supreme Heaven is taken, and by the name of Earth the elements formed in act. [Margin: 13th interpretation.]

Fourteenth, by the name of Heaven, all the heavens, the Empyrean not excluded but rather included, and all the higher things above the concave of the lunar heaven, the stars excepted; and by the name of Earth, all simple bodies, or the lower or sublunary ones, or the four elements. So understood St Augustine, *De Genesi ad literam* book 1 chapter 1, and in the *Questions on Both Testaments*, question 106; St Athanasius, *De Incarnatione Verbi*; Hamerus, with many rabbis, commentary on Genesis; Lyranus and Tostatus in their first exposition; Comestor, *Historia scholastica* on Genesis chapter 1; the *Glossa interlinearis*; Hugo Carensis in his postils; Henricus, quodlibet 6, the last question; Pererius, *In Genesim* book 1, from p. 31; and Tannerus, question 2 *De caelo*, and *Summa theologica* vol. 1, disputation 6, question 2, doubt 2, who adds, with St Thomas, that air is comprehended under the name of water. [Margin: 14th interpretation.]

Fifteenth, by the name of Heaven, whatever is above us, including the Empyrean, starry, ethereal and aerial heaven; and by the name of Earth, whatever is below us, or the elements of water and earth. So take it Caietanus on

Genesis chapter 1, Steuchus in the *Cosmopoeia*, Vielmius [Girolamo Vielmi] on Genesis, lecture 3, and Suarez, *De opere sex dierum* book 1, from chapter 3 to 9. [Margin: 15th interpretation.] Sixteenth, by the name of Heaven, heaven taken as the fourth element, and by the name of earth the three remaining elements, yet in such a way that water and air were confused and mixed together: so Innocent III understood it, on the fifth penitential psalm. [Margin: 16th interpretation.]

Seventeenth, in an entirely opposite way, by the name of Heaven the three higher elements, confused together as the matter out of which heaven afterwards came; and by the name of earth the lowest of the elements, earth. So took it Strabus in the *Glossa ordinaria*; Hugo in his *Admonitiones* on Genesis chapter 1 and *De sacramentis* book 1 chapter 6; and Richardus, *Exceptiones* book 2 chapter 7. [Margin: 17th interpretation.]

Finally, eighteenth, Hugo Carensis in his postils admitted that by the name of Heaven the two higher elements, of fire and air, and by the name of Earth the two lower, of water and earth, can be understood. [Margin: 18th interpretation.] With these in view, scarcely anything could have been thought up that has not had some patron — granted that the Fathers who understood angels by the name of heaven either spoke in a mystical sense, or took the thing located or contained under the name of what contains it. It is now worth helping the reader's memory by gathering the preceding opinions in summary into a single view, setting out on one side what they understood by Heaven, and on the other what by Earth.

Order of the interpretations	Heaven [CÆLVM]		Earth [TERRA]
1	The Idea of Heaven,	and	Earth
2	Formless matter of Heaven,	and	Earth
3	Formless matter of spiritual things,	and	of bodily things
4	Spiritual nature, or invisible and intelligible,	and	bodily, visible and sensible
5	Perfect angels	and	imperfect matter of bodies
6	The Empyrean with the angels,	and	matter under the form of corporeity
7	The Empyrean with the angels	and	the elements formed in act
8	The angels,	and	the elements confused in Chaos
9	All the heavens with the angels, or all higher things	and	all lower things below the Moon
10	All the heavens with the angels,	and	all the elements in act
11	All the heavens with the Empyrean and the angels, and with fire and air	and	Earth with water
12	The Empyrean or all the heavens,	and	formless matter
13	The supreme Heaven,	and	the elements formed in act

Order of the interpretations	Heaven [CÆLVM]		Earth [TERRA]
14	All the heavens,	and	all the elements formed in act
15	All the heavens, with aether and air	and	Earth with water
16	Heaven as the fourth element,	and	Earth with air and water
17	Fire, air and water mixed together,	and	Earth alone
18	Fire and air,	and	Earth and Water

Noſtra Opinio.

Our Opinion.

V. Although several questions are included in the title of this question — namely, what God created in the first instant of this world, and what, by which persons, and for what reason or in what words Moses, or the Holy Spirit through Moses, wished to signify as created by God in that beginning — nevertheless with a single conclusion to all these we shall re- spond in summary, and afterwards confirm it by expounding it. It runs as follows.

CONCLVSIO.

Conclusion.

In the first instant of the world God, Best and Greatest, created the Empyrean Heaven with the angels, and the starry heaven, and all the elements with their primary qualities and substantial forms, in that order as to place or position which their nature required; but without light and stars, and without the secondary qualities and the substantial forms of mixed bodies. And this Moses, and the Holy Spirit through Moses, meant to signify — though not everything to everyone, nor in the same way, nor in a single way, but in diverse ways.

VI. In support of this Conclusion I suppose, in general, four things as certain, or claim them, with full right, as things to be conceded. The first is the propriety of the literal sense, the mystical or tropical sense not being excluded. For by the rule of St Augustine and of St Gregory the Pope, and afterwards the common rule of the theologians: as long as no manifest contradiction follows from the literal sense, that sense must always be kept intact, and sacred Scripture must be taken according to the sense the letter conveys, in its proper and least figurative meaning — granted that, once this sense has been laid as a foundation, it is then permitted to build other interpretations upon it, tropological, mystical or anagogical, and allegorical. And if this is to be observed in every part of sacred Scripture, much more so in history, of which kind sacred Genesis is; for there Moses, although he was a prophet, nevertheless chiefly and for the most part conducts himself as a historian, and therefore the literal and the historical sense are taken by the sacred interpreters as the same. [Margin: 1st postulate or supposition.]

Second, I suppose that Moses — although, as regards the execution of the promulgation and the order of time, he set out in sacred Genesis the manner and

order of the creation of this world to the Hebrew people, who were for the most part rude, accustomed to knowing bodily things and indeed to worshipping them in place of God, and scarcely capable of spiritual things — nevertheless, as regards the intention, either his own or also that of the Holy Spirit, wrote for the learned and the unlearned alike, and made himself a debtor to the wise and to the unwise. For he was established by God as the prince and summit of all historians, so that he surpassed all (excepting the most holy Evangelists) in antiquity and wisdom, having once been instructed in all the wisdom of the Egyptians and afterwards imbued with knowledge infused by God; so that he might impose silence on all the philosophers and theologians who boast empty and false things about the beginning of the world, and be the one whom so many and such illustrious lights of the Church were to read through with veneration and wonder. It was fitting, therefore, that he should serve the capacity of all: that he should wish to signify certain things to the unlearned in a plainer and more obvious sense, according to the propriety of the Hebrew language, but many other things to learned men, in more numerous and subtler, yet true, ways — if not to express them, then at least to indicate them. [Margin: 2nd postulate.]

Third: Moses must not be interrupted straight after the names Heaven and Earth, as though asking him unseasonably what those names signify. For the first period is not completed there, since there follows *But the Earth*, and the particle *autem* is copulative — indeed, as Vielmius notes, lecture 3, among the Hebrews it stands for *and* — and Moses at once explains the first part of the period by the second. Just so, it would be an importunate question if someone, after the half-period *In the beginning was the Word*, were at once to interrupt that divine narrator of the generation that is from within and eternal, by asking what kind of Word that was; for the whole period must be awaited and weighed: *In the beginning was the Word, and the Word was with God, and the Word was God.* In the same way, therefore, we too must wait patiently and reverently for the whole utterance of that period, pronounced in a single breath: *In the beginning God created heaven and Earth; but the Earth was empty and void, and darkness was upon the face of the deep, and the Spirit of the Lord was borne over the waters.* For in this way the unlearned will be able to understand that the sensible heaven, the Earth, the Water and the Spirit were then created; the more learned, however, the Empyrean too, and the angels, and in many ways the air, and perhaps fire, if it is granted as something distinct from Heaven. [Margin: 3rd postulate.]

The fourth is the integrity of the Mosaic history. For in a matter of such moment Moses must not, without evident necessity, be said to have been defective or to have fallen short. Since, then, nowhere in sacred Genesis did he set out the time or moment at which God created the remaining elements, or the things that had to be founded by creation taken strictly, but only added the things that God, by the word *Fiat*, commanded of the heaven and elements already created, so that they should work with Him as secondary and instrumental causes; and since in that first period he signified those things briefly, but sufficiently for the

capacity of each, it must be said that their creation was signified by the period already mentioned. This we shall shortly show by expounding that period part by part, selecting only those things that bear on our purpose. [Margin: 4th postulate.]

In Principio creauit Deus.

In the Beginning God created.

VII. I do not dwell here on explaining the particle *in principio* — in Hebrew *Beresith* — which literally, according to the more common interpretation, signifies not only "before all the works of God *ad extra*" (which could apply even to things created from eternity, if anything could be created from eternity), but also, and above all, the beginning or first instant of time, and of all the days and years that are counted from it to this day and have been completed. And so the creation of this world is signified as made not from eternity but in time; granted that in a higher and more recondite sense it is signified that God created all things in the Word, that is, in His Son. But what bears on our matter is this: I consider the word *Creavit*. Although among the Seventy Interpreters it is expressed by the verb ἐποίησεν [Greek: epoiēsen, "made"], that is, "effected", the Vulgate version and St Jerome more correctly have *Creavit*, because the Hebrew reading has *Barà*, which means to create, or to fashion from nothing. [Margin: What creating is.]

To create, strictly speaking, is to produce the whole substance from nothing; and so, if the substance consists of matter and form, it is to produce matter and form together, from no pre-existing subject and with no prior dispositions concurring with the Creator towards that first production. So teaches the greatest part of the Scholastics, with St Thomas, part 1, question 45, where in article 5 he teaches that to be created is proper to composite and subsistent things — granted that Vasquez [Gabriel Vázquez], vol. 2 on part 1, disputation 174, chapter 2, number 17, seems to oppose it; and almost all our writers subscribe to St Thomas in this.

To be created properly, but not strictly, belongs to the rational soul, because it is not the whole and complete substance of a man. By this word, then, Moses sufficiently signified — if not to all, at least to the more learned — that whatever things were made from nothing were made by God in that first instant. For afterwards he did not use that word alone, but the words *Fiat*, *producant*, etc., and, these being presupposed, the word *creavit* taken less properly: as when he said *Let the waters bring forth the creeping thing*, etc., and shortly after added *And God created great whales*, and, of man, *To the image of God he created him*. To those, then, who were going to take the word *Creavit* strictly, he signified that there were created both the things that could not be produced otherwise — of which kind is the angelic substance, and perhaps the Empyrean — and the things that it befitted God to produce in this way, supposing that the Earth was to be created from nothing; for the reasoning was the same for all equally simple bodies. And the very name GOD warns that nothing imperfect should

be attributed to Him in His first work, for in Deuteronomy 32 it is said: *The works of God are perfect.* It was fitting, therefore, that in that first instant of operation *ad extra* He should bring forth something perfect in its order; and this would not have been so had He created either formless matter or only one of the elements. That is why St Thomas, part 1, question 66, article 1, weighing those words of Deuteronomy and following the authority of St Augustine, asserts that heaven and the elements were created by God in that beginning under their proper form; since, according to St Augustine, their forms were created together with the matter at the same time, as we shall show in question 5. And in this sense almost all the more recent theologians take the verse of Ecclesiasticus 18, *He who lives for ever created all things together*: that is, by simultaneity of the beginning and of the manner of creating, so that whatever things were created by creation taken strictly and narrowly were created together, that is, in the same instant. So too they take the words of the Lateran Council in the chapter *Firmiter*, on the Triune and One God: *Who together, from the beginning of time, created from nothing both creatures, namely the angelic and the worldly* — understanding by "worldly" the visible world composed of heaven and the elements.

Cælum & Terram.

Heaven and Earth.

VIII. Of these names in Hebrew enough has been said in question 2. But who would doubt that Moses meant by them whatever was properly to be understood — whether as all those skilled in the Hebrew language were accustomed to understand it, or as more learned men too could understand it? So these names do not signify matter that is not Heaven and Earth in act; otherwise Moses would rather have deceived the people, or by an unnecessary equivocation have given occasion for error. They signify, rather, that heaven and that Earth of which he was going to say, in Genesis 2: *Thus the heavens and the Earth were finished, and all their adornment*; and a little further on in the same place: *These are the generations of heaven and earth, when they were created, in the day that God made heaven and earth*; and in the sense in which David was going to say, in Psalm 101: *In the beginning, O Lord, you founded the Earth, and the heavens are the works of your hands; they shall perish*, etc. — by which words chiefly the sensible heavens, which are to be dissolved, are signified.

Moreover, by the name of Heaven the common people generally understand whatever is above the Earth and the Water, because of the likeness in transparency and rarity; and so the Air and the Aether as well, as will shortly be proved separately — granted that the wiser also understand that supreme and invisible Heaven which sacred Scripture calls the Heaven of Heaven and the Scholastics the Empyrean, as we shall show in question 6. By the name of Earth, on the other hand, is understood the globe of the earth with the waters now enclosed in it; but it is sufficient that, in that beginning, the Earth taken properly — that is, with its substantial form — could and should have been

understood. Otherwise, why would it be called earth rather than anything else, if it was not earth in act, nor water, nor air, nor fire, but all of them in potency?

Aerem Cæli Nomine ſignificari.

That Air is signified by the Name of Heaven.

IX. I said that by the name of Heaven Air and Aether, or fire if there is such a thing, are signified, not only among the learned but also among the unlearned, because of their likeness in transparency and rarity. For the common people make no distinction within that whole most subtle substance which extends from the surface of the earth and the sea up to the outermost blue heaven. [Margin: Air everywhere called by the name of Heaven.] And therefore in Genesis 7 the clouds are called the floodgates [cataractæ] of heaven, and in Psalm 8 it is said *the birds of heaven and the fishes of the sea*; how familiar this is to sacred Scripture we shall shortly show with St Damascene. Moreover, heaven is said to be opened when it rains, and shut when it does not rain, as in Leviticus 26, Deuteronomy 28, 3 Kings chapter 8, 2 Paralipomenon chapter 2 and Luke 4; fire and sulphur are said to have rained from heaven, Luke 17; the heaven to glow red, or to be ruddy, Matthew 16 and Luke 12; and there is *the way of an eagle in the heaven*, Proverbs 30. That is why St Augustine, explaining this passage of Genesis according to the letter, in *De Genesi ad literam* book 1 chapter 4, says: *Nor is it in any way to be thought that any element of this world has been passed over in this scripture. Air, then, is understood to belong to heaven as well, if there are any most tranquil and peaceful spaces in its parts; or to earth, on account of this turbulent and murky place, which grows thick with moist exhalation — although this too is quite often called by the name of heaven.* [Margin: The air that goes by the name of Earth.]

Well known, too, is the division of Heaven into the first, that is, the aerial; the second, the starry; and the third, the Empyrean. We shall speak of it, following Anastasius Synaita and St Damascene, below, in question 6, number 25. For now let these words of Anastasius suffice, *Hexaemeron* book 1: *When you hear that Paul was caught up to the third heaven, think the first heaven to be the air*; and those of St Damascene, *De Fide* book 2 chapter 6: *It is usual and familiar to Scripture to call the air too heaven, namely because it is above.* How truly this is said is clear, because the *birds of heaven* are so named in Job 28 and 35, Psalms 8 and 103, Jeremiah 7 and 9, Ezekiel 38, Daniel 3 and 4, and Hosea 2 and 4; and the Saviour himself names them more than once — Matthew 8 and Luke: *The foxes have holes, and the birds of Heaven nests*; Matthew 13, Mark 8 and Luke 8: *And the birds of heaven devoured it*; and Matthew 13 and Luke 13: *So that the birds of heaven come and dwell in its branches.* [Margin: Birds of Heaven, often in Holy Scripture.]

Rightly, then, St Thomas says, part 1, question 66, article 1: *Under heaven air too is included*; indeed fire as well, in the opinion of Alexander of Hales, *Summa* part 2, question 45: *Heaven, that is, fire, for there is a fiery heaven; and air, for there is an aerial heaven.* Caietanus agrees with this in his commentary

on Genesis chapter 1, where, taking Moses to have embraced all the higher things under the name of heaven, he says: *Understand that, according to the sound of the letter, all simple bodies were set out for the Hebrew people: because by the name of the heavens they understand all the higher bodies, namely the celestial ones and the spheres of fire and air; and by Earth, the earth covered with waters.* On the same chapter Vielmius says, lecture 3: *It seems to me more probable that they come rather under the name of heaven, because in Psalm 8 the Air was, without ambiguity, called heaven*, etc. Lippomanus says no differently in his *Catena*: *By the name of heaven, moreover, he embraces all things that are above: air, fire, all the celestial bodies, together with the spiritual creatures that are in the heavens.* But in a narrower sense Hugo Carensis, in his postils: *Or heaven, that is, the two higher elements; Earth, the two lower.*

Indeed Steuchus, in the *Cosmopoeia* on Genesis, gathers three heavens from the Stagirite [Aristotle] himself, when he says: *For Heaven is spoken of in three ways, on Aristotle's authority. First, that which is the dwelling of the Gods, outside the celestial whirl, where there is neither place, nor void, nor time, but only most blessed things. Secondly, heaven is said of the substance of the celestial orbs, of the Sun [?], the Moon, etc. Thirdly, Heaven is whatever there is besides the earth, to which air and aether too are joined. It is this last, then, that is mentioned in Moses.* So, according to Steuchus and Hugo, so far is it from being the case that air and fire are not signified by the name of heaven, that rather these elements alone were signified by that name — provided you grant that the starry and Empyrean heavens were made on the second day; on that matter, see questions 6 and 8 below.

Tellez too, *Physics*, disputation 40, section 1, says that air and fire are signified by the name of heaven. And before all these Pliny the Elder, book 2 chapter 38, which is headed "On the air": *So much for the world itself and the stars. Now the remaining memorable things of the heaven. For our forebears also called this heaven — which by another name is air — all that, like a void, pours out this life-giving breath.* But the use of this name is much older. Plato says in the *Phaedo* that air is called heaven by us because it is above us; and not only do Homer, *Iliad* 1, as Eustathius notes, Aristophanes in the *Clouds*, and Callimachus take air for heaven, but so do the Latin poets everywhere — as Lucretius, book 4:

> *They are established in this heaven, which is called air.*

and Virgil, *Aeneid* 5:

> *Great-hearted Aeneas, not even if Jupiter himself were my guarantor*
> *would I hope to reach Italy under this sky.*

and *Aeneid* 6:

> *Daring to entrust himself to the sky on swift wings.*

Terra autem erat inanis & vacua.

But the Earth was empty and void.

X. Where the Latin has *Inanis et vacua*, the Hebrew says *Tohù Vabohù*, or *Thohù Bohù*, that is, solitude or vanity, and emptiness — granted that the translator rendered it in the concrete. The Chaldean has *Deserted and empty*;

Aquila, *Vanity and Nothing*; Symmachus, *Idle and undigested*; Theodotion, *Empty and nothing*; Pagninus [Santes Pagnino], *Desolate and empty*; Lippomanus and Steuchus, *Empty and Void*; the rabbis, *Formless and Empty*; Ionathas, *Empty of men and beasts*; and finally Caietanus reads, following learned Hebrews, *Empty to the bottom, and empty outside*. So the Earth was vain, or seemed to have been made in vain: for although it had been made to be inhabited by animals — according to the verse of Isaiah 45, *For he did not found it in vain: he formed it to be inhabited* — it had nevertheless not yet attained its end, but lay deserted, like a solitude, under the waters. And that "in vain", as also in Isaiah 49, *I have laboured in vain*, is in Hebrew *Iethohu*.

Nor did it only lack animals dwelling on it; it was also empty of all other mixed bodies, such as stones, plants, herbs and fossils. Nor did it then hold any waters within receptacles, nor had it yet drunk in waters through its outermost skin; for then it could not have been called simply empty, or empty to the bottom and outside, that is, empty on every side; nor could it have been called *Arida* in itself and without moisture — a name it deserved of itself. For below, in Genesis 1, it is said: *Let the waters that are under heaven be gathered into one place, and let the dry land appear; and it was so. And God called the dry land earth.* Here *Arida*, in Hebrew *Iabbasa*, from the verb *Iabas*, which means "to be dried up", is used as a substantive, not as an adjective: that is, let that which is dry appear; and it was such in itself, but was not seen, because it was covered by the waters. [Margin: When and how the Earth was Arida.] In the same way the same word is taken as a substantive when, in Mat- thew 23, Christ said: *You go round sea and dry land* [aridam], that is, the earth. And the words *he called the dry land earth* are to be understood in this way: that which was the Dry Land [Arida] he called Earth, just as he called the gathering of the waters seas. In Italian we would say *E nomino la Arida, Terra*; for in Hebrew the article stands before *Iabbasa*, thus: *Vaikra Elohim Laiabbasa erez*. Here the Chaldean, Pagninus, Vatablus [François Vatable] and the Vulgate translate *and God called the dry land earth*, and the Septuagint καὶ ἐκάλισεν ὸ θεός τῆν ξήραν, γήν [recte: ἐκάλεσεν ὁ θεὸς τὴν ξηρὰν γῆν] [Greek: "and God called the dry land, earth"]. Certain Hebrews say that the perfect is put for the pluperfect, and read *And God had called the dry land earth*; but one should not depart from the Vulgate. Caietanus too, and Lippomanus in the *Catena*, teach that the Lamed which is prefixed to the noun *Iabbasa* in the manner of an article serves the dative and the accusative, so that it could have been translated *and God gave the dry the name earth. And note*, says Caietanus, *that the dry is the thing named, and earth is the name.* Tertullian puts it elegantly indeed in his Poem on Genesis:

The Dry, a name soon set upon its nature: earth.

In the words *and let the dry land appear*, too, the noun *arida* is to be taken as a substantive, not as an adjective. For the sense is not "let it be seen dried and parched", but "let that mass whose name was Arida, and which did not appear because of its covering of waters, now appear, being uncovered by the waters". This is how Basil, Ambrose, Chrysostom, Cyril, Damascene, Theodoret and

very many Fathers and interpreters understand it, as to the primary sense. In a secondary sense it can be understood as if adjectivally: dried on the surface, and made firm and more solid by God — not by the Sun, which was not yet present — and made fit to bear the feet of animals and to sprout herbs.

For although in the first instant it was created entirely dry, as its nature demanded, and did not yet have waters within itself, afterwards, up to the third day, it gradually drew in waters as to its upper parts and its skin, so that it was muddy and marshy: its dryness attracted moisture, the upper parts of the earth drank in the nearest waters in the manner of a sponge, and God did not prevent this moistening, which follows naturally from that contact. Therefore God ordered the waters to be gathered into one place — that is, within the cavities and receptacles of the sea and of the abyss lying hidden in the depth of the earth — in such a way that by the same motion he drew out or extracted, by himself or through Angels, a great part of the water that had already penetrated the skin of the earth and made it muddy and stagnant like a marsh; and so he dried the Earth's skin. For it is one thing to consider the Earth in the first instant of creation, another after that instant up to the separation on the third day, and another after the separation of the waters. In the first instant it was simply dry, but immediately afterwards it began to be moistened, and over two continuous days it was soaked more and more by the waters poured into it. After the separation, however, it received a larger quantity of waters within channels and subterranean cavities, while less water remained on its surface and skin than there had been before.

The Fathers and interpreters who held that water was mixed with the earth are to be understood of the second state, not of the first. So St Gregory of Nyssa, in his book on the history of the six days, says that it was God's work *to separate the Water from its mixture with the earth, and to collect and gather it, confined in the caverns of the earth, pressing out of the earth the moisture implanted in it by condensation and constriction.* And St John Chrysostom, homily 5 on Genesis: *Since all things* — that is, every part of the surface and skin — *were filled with waters, he ordered the multitude of the waters to withdraw into one gathering.* And Iunilius on the Hexaemeron: *So that the earth, which, covered by waters, remained muddy and weak, might by their withdrawal be made dry and fit to receive shoots.* This is how I understand Hugo Victorinus, *De sacramentis* book 1, part 1, chapter 21, when he says of the earth: *At first indeed muddy and slippery, and bare, as one that had not yet brought forth any shoots*; and St Basil, who in homily 4 of the *Hexaemeron* calls the Earth, before it appeared uncovered by the waters, *unformed, uncomposed, full of mud, and mixed with waters*. Granted, Basil thought that those waters had penetrated very deep towards the depth of the earth, when he says: *Not only did the overflowing waters flow off the surface of the earth, but whatever water too was mixed in through the dimension of the whole depth gave way, obeying the inexorable command of the Lord.* For he does not contend that no part of the land was dry and immune from water, but that whatever water there

was anywhere in the depth of the earth was separated, saving the small portion that was required for the fertility of the earth.

Granted, Philo, in the book *De mundi opificio*, said — whether from his own opinion or by way of exaggeration: *After this, since all the water had been diffused through the whole earth and had penetrated all its parts, as a sponge drinks in moisture, so that, like some muddy marsh, it was confounded out of both elements macerated together and was in a manner fermented into one undistinguished and formless nature, God orders whatever of the waters was salt, and would hinder the fertility of sown crops and trees, to be collected and to flow together into one from all the openings of the earth; and then the dry land to emerge, sweet moisture being left in it for its perpetuity.* For if God had not created those two elements mixed in this way, but they had mixed themselves, the water by wetting and the earth by drinking the water, how could the water have penetrated within the space of two days through the whole depth of the earth, which is 4000 Italian miles and more? But Philo also errs when he thinks that the water was salt before the third day; for saltness was put into the Sea afterwards, produced or increased by the burning of the Sun. Let it stand, then, that in the first instant the Earth was entirely dry.

But you will say: why then was it afterwards called Earth by God, in Hebrew *Eres* or *Erez*? Does this name not come from the root *Rus*, which means "to rush down", and does it not therefore indicate the Earth as a heap of sand apt to rush downwards? [Margin: Why is Earth named from *Ruo* or *eruo*?] I reply that it is indeed named from *Rus*: first, because it rushes downwards of itself, as far as it lies in it, on account of its weight, if part of it is placed on top of a lighter element; second, because afterwards, on the third day, it was dug up [eruta] by God, and the part of it that was in the cavities of the Seas was heaped up into mountains; third, because a great part of it was to be dug up [eruenda] by ploughing, or by digging out stones, metals and the foundations of buildings.

You will say again: why then did Moses, speaking of that first instant, use the name Earth rather than Dry Land? I reply that he did so most prudently, because he wanted to set forth at once, with two names, the whole workmanship of God created in that instant; whereas if he had said Heaven and Dry Land, he would by no means have embraced everything. So, in order to comprehend earth and water, he preferred to use the name which God gave to the Dry Land on the third day — namely, when it received the waters within itself. [Margin: Why did Moses use the name Earth rather than Dry Land?] But lest anyone take occasion of error from this, he at once added, as if correcting or explaining the name earth, *But the earth was empty and void*, so as to distinguish its nature apart from the water, which was to be named shortly after.

Quid fuerit Terra Inuiſibilis & Incompoſita, ſeu Materia informis.

What the Invisible and Uncomposed Earth, or Formless Matter, was.

XI. Theodoret, question 1 on Genesis, reads in place of the words *inanis et vacua*: *Invisible and uncomposed*, following, that is, the Septuagint translators,

who have ἀόρατος καὶ ἀκατασκεύαστος [Greek: aoratos kai akataskeuastos, "invisible and unwrought"] — that is, inconspicuous or invisible, and uncomposed, or not yet prepared. [Margin: Why invisible and formless?] And in Wisdom 11 God is said to have created the world out of unseen matter, or, as the 70 translators have it and St Augustine reads, ἔξ ἀμόρφου ὕλης [Greek: ex amorphou hylēs, "out of formless matter"], that is, out of formless matter. Granted, some have taken occasion from this to assert a prime matter without any form, or under the common form of corporeity, created prior in time to the elements; nevertheless the truer opinion is that this matter did not precede the forms of the elements except in origin and nature, as we shall teach in question 5. It was called invisible and formless, then, for three reasons, as St Thomas notes, part 1, question 66, article 1. There, after saying with St Augustine that matter was prior to forms in origin only — *as sound is prior to voice, and voice to word* — he adds that Saints Basil, Chrysostom, Ambrose and the others who call it formless are not in conflict with St Augustine, and he continues: *But other Saints take the formlessness of matter not as excluding all form, but as excluding that beauty and comeliness which now appears in corporeal creation; and in this sense they say that the formlessness of corporeal matter preceded its formation in duration.* For, as the same author explains, it lacked light, visibility and the forms of mixed bodies, especially of herbs and plants; it was invisible, then, not of itself but by accident, first because it was covered by waters on every side, and second because light was lacking. This is taught in the clearest and plainest words by Saints Basil, *Hexaemeron* homily 2; Ambrose, *Hexaemeron* book 1 chapter 7; Augustine, *De Genesi ad literam* book 1 chapter 13, question 106 on both Testaments, and sermon 134 *De tempore*; Athanasius, question 80 on the Old Testament; and likewise Severian, Procopius and Theodoret on chapter 1 of Genesis, and Alcuin in the same place, question 30. But Saints Basil and Ambrose add that it was invisible also because there was not yet a man to see it, or for whose sake God might look upon it; and Procopius, because it was not yet worth looking at, since it was stripped of every ornament. It was uncomposed and formless, on the other hand, because it was not yet separated from the waters, not yet prepared for cultivation, and not yet clothed with shoots and other forms — as the same authors teach, in Martinengus [Ascanio Martinengo], *Glossa magna*, from page 329.

And although the water too lacked fish, and the air birds, yet because these animals eventually lie down and nest on land and on the bottom of the sea and the rivers, and so belong to the earth, and because the land holds many more ornaments than water and air, it was enough for Moses to say that the Earth was empty and void, so that the same could be understood of those two elements. For of their emptiness, and that of the heaven, as regards lights and stars, he was about to say that darkness was upon the face of the abyss — which must be explained next.

Et Tenebræ erant ſuper faciem Abyſſi.

And Darkness was upon the face of the Abyss.

XII. Darkness is called in Hebrew *Vehsech*, or *Chosech*, but in the singular number — as if the Latins had the word and could say *Tenebra*; "upon the face" is *Al pene*; and Abyss is *Thehom* or *Thethoh*. The Greek edition of the Seventy translators has καὶ σκύτος ἐπάνω τῆς ἀβύσσου [Greek: "and darkness over the abyss"], that is, *and darkness over the abyss*. The Chaldean version, keeping to the Hebrew reading, translates *And Darkness upon the face of the abyss*; but the *Biblia Regia* has *and Darkness over the abyss*. Lusitanus and Caietanus: *Obscurity upon the faces, or surfaces, of the abyss*. Pagninus and Vatablus: *Darkness was on the surface of the gulf*. Caietanus, however, says that the verb "was" is not set down a second time in the Hebrew, but that the one set down earlier serves, where it is said: *But the earth was empty and void, and darkness or obscurity upon the face of the abyss*. The Vulgate, by contrast, said for clarity: *And darkness was upon the face of the abyss*.

This darkness signifies the privation of the stars in the heaven, and of light in that whole transparent body which was above the waters — namely in the air, the aether and the heaven — because that body was and is simply transparent, and so the proper subject of transmitted light. The water, by contrast, although it lacked light, was not simply transparent; and for that reason darkness is said to have been upon the surface of the abyss, not in its depth. From this it follows that through the darkness itself, obliquely, as the schools put it, its proper subject is connoted and signified; and so, in another and subtler way too, the whole of that transparent body which is above earth and water is signified to learned men, granted that it had already been expressed once by the name of heaven.

Rightly, therefore, Rupertus said, *On Genesis* book 1 chapter 8: *Especially since by the darkness which was upon the face of the abyss the neighbouring air could be understood, which was as yet irradiated from above by no lights, and is therefore rightly designated by the name of darkness*. So too Procopius on Genesis: *Darkness does not subsist of itself, but is apt to be illuminated, and needs the presence of light; for air is receptive of light*; and St Ambrose: *There was darkness, because the air itself is dark*. In the same way Comestor, *Historia Scholastica* chapter 2, the Master on book 2, distinction 12, and others understood by the name of darkness the Air deprived of light. Caietanus, on the other hand, says on Genesis that the transparent body which was the subject of this darkness was the abyss. And later I also read in Suarez, *De opere sex dierum* book 1 chapter 7, that by the darkness the air is understood, as the proper subject of light, but not fire: for he thinks that fire naturally shines and would not lack light except by violence, but that even if it had had light, it would, because of its extreme rarity, neither have been seen nor have illuminated the air, much less the surface of the water.

Rabbi Moses, by contrast, as reported by Hamerus, says that fire is signified by the name of darkness, because of itself and in its own sphere it is not luminous. He tries to confirm this from the fact that Moses the Lawgiver, in Exodus, after saying *You have heard his words out of the fire*, said a little later *You have heard*

his voice out of the darkness. But in vain: he calls the fire dark because the flame that appeared on Mount Sinai was mixed with gloom and smoke. Rightly, then, St Thomas, part 1, question 66, article 1, judged this interpretation of Rabbi Moses forced. Hugo Victorinus, however, *De sacramentis* book 1 part 1, and Richardus, *Exceptiones* book 2, give the name Darkness to the three upper Elements confused together in the manner of a mist, and the name abyss to the earth itself and its depth. [Margin: What is the Abyss?]

The name of Abyss properly signifies the unsearchable depth of the waters, as St Basil says, *Hexaemeron* homily 2: *What does abyss signify? An abundant water, to whose bottom one could not easily penetrate downwards.* Eucherius subscribes to this, *On Genesis* book 1 chapter 1: *For the immense depth of the waters is called Abyss*; and St Augustine on Psalm 41: *The Abyss is a certain impenetrable depth, and is said above all of a multitude of waters*; and *Contra Faustum* book 22 chapter 11: *The Abyss is an inestimable depth of waters*. In exactly the same way the Abyss is defined by Theophilus of Antioch, *Ad Autolycum* book 2; Iunilius and Procopius on Genesis; St Damascene, *De Fide* book 2 chapter 9; St Isidore, *Etymologies* book 13 chapter 20; Rupertus, *On Genesis* book 1 chapter 7; Gulielmus Parisiensis, *De Universo* part 1 chapter 34; and Caietanus on Genesis chapter 1 — although a little later he extends it to all transparent bodies, as Vielmius also does, lecture 8, both saying that by the name of abyss the heavens and all the transparent elements, with their depth, can be understood. But St Ambrose, restricting the word to the waters, notes acutely in *Hexaemeron* book 1 chapter 8 that the swine driven by the demons threw themselves into the lake, so that the demons, who had begged Christ that they should not go into the abyss, nevertheless ran into what they had refused. And Suidas, in Hamerus's translation, explaining the words of Psalm 103, *The Abyss like a garment is its clothing* — that is, the earth's — says that the earth is called clothed with the abyss because it was filled with small and great depths of waters. Figuratively, however, the word is transferred to signify the depth of any gulf whatever — that of the underworld, for example — and the depth of anything unsearchable or scarcely intelligible, such as formless Matter, as Martinengus teaches in the *Glossa magna*, page 355, from St Augustine, Eucherius, Catherinus, Tostatus and others. The interpreters of Psalm 41 may also be consulted, on the words *abyss calls to abyss*.

Et ſpiritus Domini ferebatur ſuper aquas.

And the spirit of the Lord was borne upon the waters.

XIII. The Hebrew has *Veruah Elohim Merachephet al pene hamaim*, that is, *the spirit of the Lord bore itself upon the faces of the waters*; and the Septuagint καὶ πνεύμα θεοῦ ἐπιφίριτο ἐπάνο τοῦ ὕδατος [recte: ἐπεφέρετο ἐπάνω] [Greek: "and the spirit of God was borne over the water"], *and the Spirit of God was borne above the water*. The noun *Veruah* signifies in Hebrew both wind and spirit. Here, therefore, air and aether can again be understood, to whose thinness and mobility the wind is most similar — granted that the same air had also been

signified by the name of heaven. Indeed, I think that by the name of spirit is understood that whole body which, besides fire and air, also embraced the heavens; for because of their transparency, not yet bounded by any opaque body, they were invisible. The heaven which was made on the second day and called the firmament, out of water made solid and spread above it and below the Empyrean, was made visible; it is everywhere recognised as such by the Fathers, and is distinguished from the Empyrean, which is invisible to us, as I shall teach in questions 6 and 8. Since, therefore, they were then invisible not only through a lack of light but also through a lack of opacity, they were in a manner spiritual.

Pliny, however, restricting this name to the air, says, book 2 chapter 5: *Nor do I see that there is any doubt about the elements, that they are four: Fire highest, from which come those eyes of so many shining stars; next Spirit, which the Greeks and our own people call by the same word air — this life-giving breath, passing through all things and interwoven with the whole; that by its force the earth, suspended together with the fourth element, that of the waters, is balanced in the middle of space.* Indeed, in sacred Scripture too, wind, breeze and air are often signified by the name of the spirit of the Lord, by the common consent of the interpreters; as when it is said, Psalm 147: *his spirit shall blow, and the waters shall flow*; and Psalm 148: *Fire, hail, snow, ice, the spirit of the storms, which do his word*; and Isaiah 40: *The grass is withered and the flower has faded, because the spirit of the Lord has blown upon it*; and [Margin: Air and Aether under the name of Spirit.]

Isaiah chapter 49: *Like a violent river, which the spirit of the Lord drives*; and Psalm 47: *With a vehement spirit you shall break the ships of Tharsis*. Finally, in 4 Kings chapter 19, where it speaks of the vehement Wind, which indicated Elijah's excessive zeal, and of the whistling of a gentle breeze set against it, which signified zeal tempered with mildness, it is said: *a great and strong spirit, overturning mountains and overturning rocks before the Lord; the Lord is not in the spirit*, etc., *and after the fire the whistling of a gentle breeze*.

And so the words *And the Spirit of the Lord was borne upon the waters* must, or can, be understood of the air according to the proper sense of the letter: so affirm Tertullian, *Against Hermogenes* chapters 31 and 32; Origen, *Peri Archon* book 1 chapter 3; Theodoret, question 8 on Genesis; Diodorus of Tarsus, Procopius, Abulensis, Oleaster, Pererius and Ludovicus Stella on Genesis; Vasquez on the first part, disputation 108, chapter 1; and Suarez, *De opere sex dierum* book 1 chapter 7. Indeed St Augustine too admitted the same in the unfinished book *De Genesi ad literam*, chapter 4, saying: *A third opinion about this spirit can arise: that the element of Air should be believed to be expressed by the name of spirit, so that in this way the four elements from which this visible World arises have been expressed — namely Heaven, Earth, Water, and Air.* And Anastasius Synaita, setting out this explanation in *Hexaemeron* book 1, adds: *This is in keeping with the letter of Moses, as far as the history itself is concerned*; and St Athanasius prefers it, question 81, which is the second of the Old Testament.

Plato too, reading the history of Moses and not rising mystically to the Holy Spirit, of whom he knew nothing, understood air by attending to the sound of the letter, as Rupertus Abbas reports, *On Genesis* book 1 chapter 8. For he says: *This love, this goodness of the Creator, is the Holy Spirit. Not knowing this, Plato, when he had read this Scripture, judged it to be the spirit of the world, that is, the air, which in the order of the elements stands above the waters as being lighter; and because he suspected that by heaven too — of which it had already been said, In the beginning God created Heaven and Earth — fire was signified, he thought that only four elements, namely fire, Earth, Air and Water, were enumerated in this place.* [Margin: Plato read Moses; and how he understands him.] Rabbi Moses, who was certainly skilled in the Hebrew language, understood the very same, as Hamerus testifies on Genesis chapter 1, at the words *and darkness was upon the face of the abyss, and the spirit of the Lord*, etc., on which that Rabbi said: *The elements too were named according to the order of their natural position: since first he set down earth, and above it water, above which is air, above which fire stands.* That fire too is comprehended under the name of spirit — as also in that verse of Ecclesiastes 1 about the Sun, *Surveying all things in its circuit, the spirit goes on* — is affirmed by Abenezra [Ibn Ezra], David de pastris, and Vallesius, *De sacra philosophia* chapter 1; nor does Pineda [Juan de Pineda] dissent there. And by the name of spirit Hippocrates too understood fire, in the book *De flatibus*, and Aristotle, *Meteorologica* 1 chapter 4.

XIV. Nor is it an obstacle that the words *Spirit of the Lord* have been understood otherwise by many Fathers. [Margin: Other interpretations of the Spirit of the Lord upon the waters.] Caietanus, with Procopius, understood them of the Angels moving the Heavens; Aegidius, on book 2, distinction 12, question 2, article 3, of God moving the Heavens; of the good and well-disposed will, St Augustine, *De Genesi ad literam* book 1 chapter 5, and with him Tostatus and Hugo Carensis in the postils, Lyranus, the *Glossa ordinaria* and the *Glossa interlinearis*, Hugo Victorinus in the annotations, chapter 7, and Alexander of Hales, part 2, question 46, member 5; of the eternal Wisdom of God, Steuchus in the *Cosmopoeia*. But very many understood them of the Holy Spirit: namely Tertullian, *De baptismo* chapters 3, 4 and 5; Pope Clement, *Recognitions* book 6; St Cyprian, the sermon on the Holy Spirit; St Jerome, letter 83 to Oceanus, and in the *Hebrew Questions on Genesis*; St Augustine, the unfinished book *De Genesi*, chapter 4, and *De Genesi ad literam* book 1 chapter 7; St Ambrose, *Hexaemeron* book 1 chapter 8, and in the prologue to book 2 of *De Spiritu Sancto*; St Basil, *Hexaemeron* homily 2, and *Against Eunomius*; St Nyssenus [Gregory of Nyssa], in the book of testimonies on the Trinity against the Jews; St Athanasius, in the sermon against the heresies and in the letter to Serapion; St Cyril of Alexandria, *Against Julian* books 1 and 3; St Damascene, *De Fide* book 2 chapter 9; St Isidore, *De summo bono* book 1 chapter 10; Anastasius Synaita, *Hexaemeron* book 1; Procopius, Eucherius, Diodorus, and Claudius Victor, book 1 on Genesis; Philastrius, in the book *On Heresies*; Bede, in the book on the creation of the 6 days; Optatus of Milevis, *Against Parmenianus*

book 5; Rupertus, *On Genesis* book 1 chapter 8; Peter Comestor, in the history of Genesis, chapter 2; St Thomas, part 1, question 74, article 3, reply to 4; Albert the Great, *Summa* part 1, *On the 4 coevals*, question 12, article 11; and Albinus, question 29 on Genesis.

Their words are cited by Ascanius Martinengus in the *Glossa magna*, from page 372 to 385, who contends that this is the spirit by which the whole World is stirred and ruled, according to Trismegistus, Plato, and Virgil, *Georgics* 1, in the verses *Principio caelum* etc., *Spiritus intus alit* etc.; that this is the Mind of which Anaxagoras spoke; and that this is that Love which Hesiod and Parmenides said was the first of all the Gods. But these things, I say, are no obstacle, because, as Suarez notes, *De opere sex dierum* book 1 chapter 7, they can be understood to have spoken in a Mystical sense; and Martinengus himself, page 376, admits that it would not have been fitting for Moses to want to set before the uncultured Hebrew people, out of season, in the literal sense of the history, the most hidden mystery of the Most Holy Trinity, or the Holy Spirit. And indeed, if he did not want to set out to them either the Empyrean or the Angels, much less did he want to set out the Holy Spirit — nay, not even to learned men, as regards the literal sense; especially since there is no reason why he should either be silent about the divine Word or say that the Holy Spirit was borne above the waters only, and not rather poured over and into the whole world; whereas the reason why air and aether are above the waters is their natural lightness.

XV. Nor are the words *was borne upon the waters*, in Hebrew *Merachephet*, an obstacle, although they seem unable to be applied to the air, which neither moves naturally in its own place, nor had to be moved from outside at that time for any other cause. [Margin: What *was borne upon the waters* signifies.] For the Syriac version has *was cherishing the waters*, or others, *was brooding at rest upon the waters*; and so Vielmius on Genesis chapter 1: *This word indicates the site and place of the air where it was created, and not in fact a commotion and wind, but rather rest, as when a hen sits on eggs to make them living* — as Diodorus, Basil and almost all the rest write. St Jerome too asserts the same in that place, namely that it signifies not local motion but cherishing or brooding. Or, as Suarez says, *De opere sex dierum* book 1 chapter 7, it signifies the pre-eminence of a thing that requires a higher place, or that extends itself upwards above the water, or that contains the waters beneath itself. Or certainly it signifies the nature of the air, which is easily movable, as Theodoret teaches, question 8 — granted that others teach that a slight motion, after the manner of a breeze, put into the air by God for hidden reasons, can be understood; which, although it does not wholly displease Vielmius, does displease Suarez. Finally, all who understand the Holy Spirit there by the name of spirit are forced to deny it local motion: for God does not move locally.

So far, then, we have that Moses sufficiently signified, at least to learned men, the creation of the aether, or of fire and air, by the verb "create", because these elements were made out of nothing — whether under the name of heaven, or of darkness, or of spirit. Granted, St Basil, *Hexaemeron* homily 1; St Ambrose,

Hexaemeron book 1 chapter 6; St Jerome on Job chapter 38; Eucherius, Caietanus and the *Glossa ordinaria* on Genesis hint that these were indicated by the name of Earth, because air and fire, not to mention water, are enclosed in the bowels of the earth; but at that time they were certainly not enclosed.

Quæſtio 4. Quot & Quæ Elementa Priſci, ac præcipuè Patres ex Moyſe agnouerint ?

Question 4. How many and which Elements did the Ancients, and especially the Fathers, recognise from Moses?

XVI. That there are four simple bodies beneath the heaven, which are called elements — according to the Peripatetics, to say nothing of the Epicureans and Hippocrates — namely Fire, Air, Water and Earth; that they are called simple because, although they are composed of matter and form, they nevertheless have no mixture of the secondary qualities, but are held together by the properties of the primary qualities; and that they are called elements because all mixed bodies consist of them, either in act or virtually — all this is well known from Aristotle, *De caelo* 3 and 4, and his interpreters, and from most other Philosophers. [Margin: First opinion: four Elements distinct from the Heaven.] In their favour stands that very strong argument drawn from the combination of the 4 primary qualities: namely, that just as there is an Element dry and cold, which is Earth, and one cold and moist, which is Water, so there should be one hot and moist, namely Air, and one hot and dry, namely Aether or Fire; so that between the extremes of contraries there should also be means, and one element might be converted most readily into another that is akin to it [symbolum], or suffer as little as possible from the contrary extreme. This opinion was embraced, and elegantly set out, by St Gregory of Nyssa, *Philosophy* book 3 chapter 2 — or certainly by Nemesius, to whom some ascribe that work; by St Basil, *Hexaemeron* homily 4; St Ambrose, *Hexaemeron* book 3 chapter 4; St Anselm, *De imagine Mundi* book 1 chapter 3; Gregorius Pisides, *De Mundi opificio*; Hermias the Christian Philosopher, in the book entitled *Irrisio gentilium Philosophorum* [The Mockery of the Pagan Philosophers]; and many of the Poets, especially Ovid, *Metamorphoses* book 1.

Others, however, admitted the four elements in such a way that they counted the Heaven, that is, the aether, in fourth place, and called it fire, or fiery, or not distinct from the element of fire. [Margin: Second opinion: four Elements, the Heaven being taken for fire or for the fourth element.] For the Stoics called the heaven a mobile ardour; Pythagoras calls it flame, and Heraclitus fire; and Empedocles, according to Clement of Alexandria, *Stromata* book 5, enumerating the four parts of the World, said:

Earth, and the overflowing Sea, and the moist Air, Titan, and the Aether, which binds all things in a circle.

For if the aether is that in which Titan and the Titanian stars are, and which contains all things within itself, it is certainly the heaven. Pliny the Elder's saying in book 2 chapter 5 rather favours this: *Nor do I see it doubted that the*

elements are four; the fiery one highest, from which come those eyes of so many shining stars. Moreover, Plato too, when he read Moses, judged that Fire, one of the four elements, was signified by the name of Heaven, as Tostatus reports in the postils on Genesis 1, and Rupertus in book 1 of the Commentary on Genesis, chapter 8, in these words: *Plato, when he had read this Scripture*, etc., *because he suspected that fire too was signified by Heaven, thought that only four elements, namely Fire, Earth, Air and Water, were enumerated in this place.* Nor does St Augustine dissent, in the unfinished *De Genesi ad literam*, chapter 4, when he says: *So that in this way four elements have been expressed, from which this visible World arises: namely Heaven, Earth, and Water, and Air.* Nor, again, does Bede, in the *Exposition of Genesis*, speaking thus: *Nor should it be thought that air has been passed over in this scripture, since the World consists of four elements, that is, of Heaven, Air, Water and Earth. But the highest part of the air, which does not receive moist exhalations, is assigned to the heaven; while the lowest part of the air, in which are winds and rains, is assigned together with the earth.* And Pope Innocent III, on the 5th penitential psalm: *In the creation of the world Heaven and Earth were created together, the first and the lowest among the four elements, and with them likewise the two means, namely air and water, mixed and mingled together, but afterwards they were separated.* And Hugo Carensis in the postils: *Heaven, that is, the two upper Elements; Earth, the two lower.*

[Margin: Five Elements according to Pythagoras.] Pythagoras, however, seems to have posited five elements, that is, the heaven and the four commonly recognised, since Plutarch, *De placitis* book 2 chapter 6, says: *Pythagoras thinks that God [?] the creation of the world from fire and the fifth element* — on account of the five regular bodies, on which see number 18.

[Margin: Third opinion: of three elements only.] Next to these are those who recognised and asserted only three Elements, Earth, Water and Air. Franciscus Patritius [Francesco Patrizi], *Pancosmia* book 22, shows that Zoroaster, Hermes and Orpheus were of this kind; and among the more recent there is Copernicus, book 1 chapter 8; Cardano, *De subtilitate* book 1, who calls Earth and Water passive and Air active; and Tycho, *Progymnasmata* volume 1, pages 91 and 92, and frequently in the letters to Rothmann. There Tycho contends that there is no fire between the air and the aether, but that the air extends almost as far as the Moon and differs insensibly in transparency from the aether, or aetherial air; and yet that it is not, on that account, of the same nature and species as Air. Kepler holds the same in the *Optics*, in the *Mars*, and in the *Epitome of Astronomy*, calling the Aether, or Heaven of the Planets, aetherial air throughout. These views are strongly favoured by Claudius Marius Victor, Tertullian and Strabus, who are to be reported below at number 18. Add to these Io. Penna [Jean Pena] and Rothmann, who, as Tycho testifies in volume 1, page 92, recognised nothing besides Earth and Water except air extended as far as the highest Heaven.

[Margin: Fourth opinion: of two Elements only.] Many of the Ancients before Aristotle, on the other hand, recognised only two elements, namely

Earth and Water; for they will call [?] air a void. And so Paulus Burgensis [Pablo de Santa María], in the additions on Genesis, judges that only these two were expressed by Moses, so that he might accommodate himself to the less cultivated. Telesius, on the contrary, recognised only two elements, Fire and Earth, which were indicated by Moses under the name of Heaven and Earth, while Water and Air are by no means first bodies, but second.

Quæſtio 5. Quid fuerit Chaos apud Poetas, Philoſophos ac Theologos ?

Question 5. What was Chaos among the Poets, Philosophers and Theologians?

XVII. Laertius [Diogenes Laërtius] relates, in book 1, in the life of Epicurus, that Epicurus turned from teaching Grammar to Philosophy after neither the Grammarians nor the Sophists had satisfied him when he asked what Chaos was in Hesiod. A greater necessity is laid on us, however: that of distinguishing the Chaos which Moses indicated in sacred Genesis — and which sacred Scripture elsewhere, and the Fathers, indicated — from that profane one, teeming with errors, which some Philosophers or Poets dreamed of. Now Chaos is a Greek noun, called Χάος [Greek: chaos], not so much from Χάνειν [Greek: chainein, "to gape"], which is to gape from the depths, as from Χέω [Greek: cheō, "to pour"], which is to pour, and by pouring to confound many things into one — in the way that the fire of Corinth melted various metals and fused them into one bronze, called Corinthian from that. And so it signifies a confusion of many things mixed or heaped together. In Hebrew, however, it is called *Aphar*, that is, slime, as our Salianus thinks in the *Apparatus*, chapter 11; or rather it is signified by *Erer Thohu*, that is, empty Earth, and *Vabohu*, that is, void — or, as our Fernandius translates, *Solitude and emptiness*. From this, Steuchus thinks in the *Cosmopoeia*, Chaos was so named, with the letter Thau changed into Chet. Hence also, by metaphor or a certain analogy, the darkness and filth of the Underworld are called Chaos by Virgil, *Aeneid* 6:

Gods who hold dominion over souls, and you silent shades, And Chaos, and Phlegethon, places silent far and wide in night.

and by Valerius Flaccus, *Argonautica* book 7:

Through Chaos the blind shades come to meet them, without voices.

Indeed, even in the Gospel, Luke 16: *Between us and you a great chaos is fixed.* The same word is transferred to night, on account of the confusion of colours and of things, as in the Church's hymn for Sunday vespers:

You who command that morning, joined to evening, Be called day, Foul Chaos glides in,

that is, night comes on. Properly, however, it signifies that rude and undigested mass from which all bodies were afterwards made; but its better-known senses vary among Writers. [Margin: First and second notion of Chaos.] First, Hesiod and certain of the ancients feigned Chaos as unbegotten and as existing before all the Gods, or as unbegotten matter. Second, very many others said that it was a certain formless Matter, or one under a single rude form, which in act was neither heaven nor any of the elements, but only in potency, as the

seedbed of all corporeal things. Thus Trismegistus, in the ἱερολόγω [Greek: hierologō, "Sacred Discourse"], says that all things were enclosed in Chaos δυνὰμη [Greek: dynamei, "in potency"], that is, in power and virtue, before they were divided and separated. Hence Euripides, as quoted by Steuchus in the *Cosmopoeia*:

Heaven and Earth were of one form. But when, embraced together, they had been parted, Every thing came forth and emerged into the light.

And Ovid, *Metamorphoses* 1, said expressly: when

..... No thing kept its form.

and in the same place:

Before the Sea and the Lands, and the Heaven that covers all, Nature had one face in the whole world, Which they called Chaos, a rude and undigested mass, Nothing but inert weight, and heaped together in the same place The discordant seeds of things not well joined. And where there was earth, there too was sea, and air. Cold things fought with hot, moist with dry, Soft with hard, things having weight with things without weight. This strife God, and a kindlier nature, settled.

And St Gregory Nazianzen, in the poem *In Praise of Virginity*:

Night once covered all things, dreadful with darkness. There was no splendour of Dawn, etc. *But a reckless motion rolled all things, confused together, Bound by the heavy chains of darkness, Which ancient Chaos had spread over the whole world.*

So too Claudius Marius Victor sang, in the Commentary on Genesis:

And so that rich Wisdom might make this World, It brought forth all things together; but after this the seeds of things

Adorned, formless as they were, with forms laid over them.

Indeed, Diodorus Siculus too, as quoted by Eusebius in book 1 of the *Praeparatio Evangelica*, chapter 4, said: *For they report that before the beginning of all things there was one form of Heaven and Earth, the two being confused together; afterwards, when they had been separated*, etc.

[Margin: Unseen matter: what is it?] Taking Chaos in this sense, then, not a few have judged that it was signified by Moses under the name of Heaven and Earth, or at least under the name of the empty and void Earth; or also in Wisdom 11, where it is said: *For your Almighty hand, which created the world out of unseen matter, was not without power*; or finally by St Paul, Hebrews 11: *By faith we understand that the worlds were framed by the word of God, so that visible things might be made out of invisible ones.* That passage of Wisdom, in the Greek of the Seventy translators, reads ἔξ ἀμόρφου ὕλης [Greek: ex amorphou hylēs, "out of formless matter"], *out of formless matter* — of which I have already spoken, question 3, number 11.

And so, first of all, St Augustine, *Confessions* book 12 chapter 20, and book 1 of *De Genesi contra Manichaeos*, says: *The first matter was made confused and formless — the things which are distinct and formed — which I believe the Greeks call Chaos; for so too, we believe, it was said in another place in the praises of God: You who made the world out of formless matter, which some codices have as "out of unseen matter".* And in chapter 7: *That formless matter, then, which God made*

from nothing, was first called Heaven and Earth, and it was said, In the beginning God created Heaven and Earth — not because this already was, but because this could be. And in the unfinished book *De Genesi ad literam*, chapter 3, he calls this matter *the Seed of heaven and earth*; but he says this only by way of inquiry, not of assertion, for he says: *Let this much be inquired on this point; for none of these things could be rashly affirmed.* From book 1 of *De Genesi ad literam*, chapter 14, however, it is clear that he gave this matter a priority not of time but only of origin, and that it preceded the forms in the way that sound is prior to voice. For he says: *Not because formless matter is prior in time to formed things, since both were created together, both that from which it was made and that out of which it was made. For just as voice is the matter of words, and words indicate formed voice — and yet he who speaks does not first emit a formless voice which he can afterwards gather and form into words — so God the creator did not make formless matter at an earlier time and afterwards form it. For he created matter already formed. But because that from which something is made, even if not in time, is yet prior by a certain origin*, etc.

Philo too, in the book *De Mundi opificio*, after saying *that Moses reached the summit of Philosophy*, adds that, according to Moses' narration, a substance was made by God *having nothing good of itself, which yet could become anything; for of itself it was devoid of every quality, undigested, inanimate, full of rudeness, confusion and discord, but capable*, etc. St Gregory of Nyssa joins them, in *On the history of the six days*, where he says of God the craftsman: *But since he can do all things, he prepared beforehand, for the making of things, all things together by which matter is compounded, by a will equally wise and not [?] powerful, and gathered them together — light, heavy, solid, dense, rare*, etc.; *for none of these is matter by itself, but when they have concurred with one another they make up matter.* And not much later: *For when the whole nature of things had already been created in a heap, in one moment of the divine will, promiscuously and indistinctly, and all the elements had been mixed with one another*, etc. The other St Gregory, Nazianzen, indicates the same matter in the oration on the Holy Spirit: *It is agreed that God in six days set matter in place and formed it*, etc.; and St Gregory the Great, on Job, book 32: *For the substance of things was created at once, but it was not created at once in its species; and what came into being at once in the substance of matter did not appear at once in the species of form.* Philastrius expressly agrees, in the catalogue of heresies, heresy 63, saying: *There is another heresy which is in doubt about the earth, saying that this is the only one and that there is no other: not knowing that there is another, which is as it were the womb of all things and contains all things; which is found in the scriptures as* ὕλη [Greek: hylē, "matter"], *that is, matter; which is invisible and uncomposed, and which was made by God on the first day; whereas this one on which we live is shown to be founded upon water, as David said: You who founded the earth upon the water.* [Margin: Psalm 103.] No less clearly Tatian, in the oration against the Greeks: *This is how the matter stands. It is clear that the whole machine of the world, and whatever stands established in it, was constituted out of matter; but that matter itself was produced by God, so that it is understood partly as rude and formless, before it was separated, and partly as conformed and set in order, after its*

separation was accomplished. Theophilus of Antioch too, explaining the first and second verses of chapter 1 of Genesis in book 2 *To Autolycus*, concludes: *Sacred Scripture does this first of all, and admonishes us, so as to teach that matter was in some way made by God, from which he constituted the World and adorned it into a fitting order.* Very briefly, Alcuin, question 19 on Genesis: *He who lives for ever created all things together in formless matter*; and he repeats the same in question 28.

Let us come to later centuries. Peter Lombard, or the Master of the Sentences, book 2, distinction 12, explaining the first verse of Genesis, says: *Heaven, that is, the Angels, and Earth, namely the matter of the four elements, still confused and formless, which was called Chaos by the Greeks; and this was before every day*; and further below: *Some indeed have taught that all things were created together in matter and form, which Augustine seems to have held. Others have rather approved this, and asserted that first matter, rude and formless, holding the commixture and confusion of the four elements, was created; and that afterwards, through the intervals of six days, the kinds of corporeal things were formed from that matter according to their proper species. This opinion Gregory, Jerome and Bede, and many others, commend and prefer. It also seems to fit the scripture of Genesis better.* Afterwards, however, he seems to recognise Chaos, and that matter, as made of the Elements in act, but confused and not yet adorned, as we shall say in the 4th opinion, to be reported at number 19 — although St Bonaventure counts him in this second class, in which Bonaventure himself most evidently stands, on book 2, distinction 12, question 3, article 1, asserting: *There is another, more reasonable way of speaking: that that matter was produced under some form, but that this was not a complete form, nor one giving complete being to the matter; and therefore it did not inform it in such a way, because the matter would still be called formless; nor did it so far bring the appetite of matter to an end, because matter still desired other forms.* And he gives the example of the embryo in the mother's womb, whose form, however, he says is more perfect than that rude form under which matter was first created.

Alphonsus Tostatus, in the postils on Genesis, prefers this opinion, though he does not condemn the one we shall report in fourth place, at number 19. For after he had said: *The second position: that at the beginning of time incorporeal things, namely the Angels, were created, and the matter of all corporeal things under a certain common form of corporeity, not determined to any species of created things; and that afterwards, over the days, the distinction of things into species was made from that matter; and this position is held by Strabus, Bede and other doctors* — he added: *This position is very much in conformity with the letter.* Then, interpreting the words *upon the face of the abyss*, he clearly teaches the mode of the creation and distinction of things, saying that that matter lacked heaviness, lightness and the four first active qualities, and had only density mixed with rarity; that its upper part, which is now above the concave of the Moon, passed into the matter of the celestial bodies, and the lower part into the elements and the other sublunary bodies; and that from the part most condensed of all the earth was made, and then water, air and fire, with less density and greater rarity and

expansion. Lyranus likewise, in the postils, ascribes this to Strabus and Bede, and does not himself disapprove it. Let Ambrosius Catharinus be added to these. On the first chapter of Genesis, at the word *Earth*, relying on the words of Wisdom 11, *He created the world out of unseen matter*, and after adducing the authorities of the Poets, Philosophers and Fathers, he concludes with these words: *We must therefore confess that the matter from which the world was produced was prepared beforehand, unless we wish utterly to violate the words of scripture. For if matter had been created at the same time as some creature, how could it truly be said that the world was made out of it?* He then teaches that its act was very weak, confused, and more imperfect than the simple forms of the elements themselves.

XVIII. [Margin: Third opinion on Chaos.] The third opinion places Chaos, or the matter of the Heavens and of the elements, under the predominant form of one element or simple body. That body some called iron[22], as Xenophanes did; others watery and fluid, as Thales of Miletus and Xenocrates; others airy, as Anaximenes; others fiery, as Parmenides; or made of atoms of air and fire, as Epicurus. [Margin: The order of the separation of the Elements.] But as to the order in which these men — or those who held that the elements were in that chaos in act, but mixed — thought that the remaining elements and the heaven were produced or separated, some held one view and some another, as reported in Plutarch, *De Placitis* book 2 chapters 6 and 7. For very many of those called Physicists said that the beginning was made from the centre and from the earth, because the centre is the beginning of a globe:

Empedocles, however, held that air was separated out first, then fire, afterwards earth, and lastly water. Plato, for his part, judged that the visible world was made in the likeness of the intelligible world in such a way that, just as in it the soul is prior and then the body, and in the body the fiery and earthy portion comes first, so fire and earth came first, and then air and water. So Plutarch, chapter 6; but in chapter 7, reporting Plato's very words, he says that in Plato's view *Fire was made first, then aether, after it air, from there water, and afterwards earth.* In chapter 6, however, he speaks of Pythagoras a little differently; for after saying *Pythagoras: the beginning of the world from fire and the fifth element*, he adds that the world was made according to the figure and order of the five regular bodies. [Margin: The 5 regular bodies as a type of the fabric of the world, according to Pythagoras [?] and Plato.] It is worth bringing in Plutarch's words: *Pythagoras: since the solid figures, which are called mathematical, are five, the earth was made from the cube, fire from the pyramid, air from the Octahedron, that is, the figure of eight seats or faces; water from the Icosahedron, that is, the figure of twenty seats; and the universal globe from the Dodecahedron, that is, the figure sitting on twelve positions. In all these Plato Pythagorises.* Finally, St Gregory of Nyssa, *On the history of the six days*, teaches that fire leapt out of Chaos first,

[22] printed *ferreum*; the sequence of the elements, and Xenophanes' own doctrine, want *terreum*, earthy

and that all things were illuminated by it; for by the light that was made first he understood the separation of Fire from Chaos.

XIX. [Margin: Fourth opinion on Chaos.] The fourth opinion recognised in Chaos the elements in act, according to their simple forms, but mixed — either all of them or some. Such was that celebrated homoeomeria of Anaxagoras, and of Empedocles — except that Anaxagoras thought that other substances too lay hidden in it. But St Basil, homily 2 on the *Hexaemeron*, expressly rejects, first, the opinion of formless matter adduced in second place, saying: *But the depravers of the truth, not accommodating their own mind to Scripture but dragging the mind of the Scriptures to their own will and perverting it, say that matter is hinted at by these words. For this, they say, is invisible and unadorned by its own nature, inasmuch as it is separated from every quality, form and figure.* Then he explains the reason why the earth is called invisible and uncomposed: namely, because it was covered by waters. And in the first homily he had taught that the remaining elements were then created under their own forms, saying: *From two principles he indicates the essence of the whole universe: ascribing to Heaven the prerogative of dignity in generation, and to earth the second place. Whatever is intermediate between these took its beginning together with the very extremes. Therefore, although he said nothing of the other elements — fire, I mean, air and water — yet it is fitting that they be understood by your own skilful wit.* St Ambrose nearly copied these words and subscribed to them, *Hexaemeron* book 1 chapter 6; and most openly St Damascene, *De Fide* book 2 chapter 5: *Our God himself, who is glorified in Trinity and Unity, made Heaven and earth and all things that are in them, leading them from nothing into being. All these, indeed — Heaven, Earth, air, fire, water — not out of a subject matter.* And chapter 10: *Earth is one of the four elements, endowed with dryness, cold and heaviness, and unmoved; produced by God on the first day out of nothing into existence. For Scripture says, In the beginning God created heaven and earth.*

St Augustine taught similar things, as we saw above, since he teaches that forms were concreated with matter at the same time; and so did Junilius in his *Hexaemeron* — for he says expressly that the four elements, of Earth, water, air and fire, were created with the heaven, granted that not all were expressed by Moses, and that air and fire lay hidden within the earth, while water was above the earth. Alcuin likewise, question 20 on Genesis, enumerating all the things that were created or made from nothing, and so not from that unformed matter, says: *Which creatures were made from nothing?* and answers: *Heaven, Earth, Angels, light, air, water, the soul of man* — where by the name of light he understands fire, as St Nyssenus also does, as will be seen later when we treat the production of Light and of the stars. And the author of the *Glossa ordinaria*, Strabus: *All the elements at first sight mixed and confused, and this whole space of air full of waters — not such as they are now, but like thin clouds.* Very close to this view is the opinion of Hugo Victorinus, chapter 5 of the preface to Genesis, where, after asserting that the Empyrean, the Angels and matter were created at the same time, he says: *It was created formless, not wholly lacking form; but it can*

be called formless by comparison with the beauty and order that followed. Afterwards he describes the disposition and order of the elements in Chaos in this way: *The earth was in the middle, having in itself channels and veins, receptacles, that is, of the waters flowing both over the earth and within it. The three remaining elements, confused into one, after the manner of a thick cloud, were borne above the earth from every part and surface of the earth up to the highest Empyrean; and therefore they are called by the name of earth where it says: God created Heaven and Earth.* He confirms this more fully in book 1 of *De Sacramentis*, part 1, chapter 6; nor does the Master reject it, book 2, distinction 12. And Richard of Saint Victor, book 2 of the *Exceptiones*, thinks that the three upper elements, confused together, are designated by Moses under the name of heaven; for he says: *He calls heaven three elements, fire, air and water, which were mixed in one confusion, or confused in one mixture, floating around the fourth, which is earth; and the earth, balanced by its own weight, settled in the middle and at the bottom of the three.* Besides these, St Anselm of Canterbury, *De imagine mundi* book 1, calls the matter from which all things were created the four elements: *In matter, so that all corporeal things might be created out of four elements.*

Finally, that Chaos was the heaven and the four elements, complete in act with their substantial forms, is taught by Theodoret in the questions on Genesis; Rupertus, book 1 on Genesis, chapter 6; Hugo Carensis in the postils; Ascanius Martinengus, *Glossa magna* page 277; Suarez, *De opere sex dierum* book 1; Henricus, *Quodlibet* 6, the last question; Pererius, book 1 on Genesis, page 31; and Tannerus, question 2 *On the heaven.*

[Margin: The order of the Elements in Chaos.] Among the Authors of this Class, however, there were various dispositions of the Elements in Chaos. According to Empedocles, Saints Basil, Ambrose and Damascene and most of the Greeks, St Anselm, Alcuin, Caietanus and Pererius, the Earth was, in that first instant, in the lowest place; above it water, above the water air, above the air fire, and above the fire the aether or heaven. According to Junilius, however, fire and air were enclosed in the Earth, and water was above the earth. According to Strabus and Lyranus, Hugo Victorinus and Richard of Saint Victor, the Earth was at the bottom, and above it the three remaining elements, mixed with one another after the manner of a thick cloud and extended as far as the Empyrean, as Hugo says, or as far as the Heaven, as others say. But according to Pope Innocent the heaven was separate, in the place of fire, and so was the earth, while water mixed with air was in the middle — so he says on the 5th penitential psalm. How this matter was called formless, invisible and uncomposed was sufficiently explained in question 3, number 11.

XX. [Margin: Fifth opinion on Chaos.] The fifth opinion, besides the heaven placed outside Chaos, recognises in Chaos only Earth and Water in act, and holds that all corporeal things were afterwards made from these. Homer seems to have been of this opinion, when he brings in men imprecating utter destruction on their enemies with that verse:

But may you all return to earth and water.

Adducing this verse, St Justin says: *by vehement anger, dissolving them out of earth into their ancient nature*, as Eugubinus too noted, *De perenni philosophia* book 1. Orpheus holds the same: he called that primeval matter ἰλὺν [Greek: ilyn, "slime"], that is, Slime composed of earth and water, which the Hebrews call *Aphar*; although in Patritius he posited three elements. This opinion is learnedly defended by Gulielmus Parisiensis [William of Auvergne], chapters 31 and 39; Halensis, part 2, question 45, member 2; Rupertus, book 1 on Genesis, chapter 6; and our Molina, *De opere sex dierum*, disputation 2. Salianus subscribes to Molina in the *Apparatus* to the *Annals*, chapters 6 and 11, and so does our Fernandius on Genesis, chapter 1, section 2. Steuchus too says in the *Cosmopoeia*: *The beginning of all earthly things was formless hylen, and this was the best plan for creating the muddy earth, so that all things might be made from it; for we have shown that hylen is as it were ilyn and slime.* And he teaches that air and fire were afterwards made from these, and adds that Moses rightly called the Earth empty and void, that is, *Thohu* and *Bohu*; that this is the very thing which among the old Latins was *Chohum* — for so they called the World in its first origin, as Festus Pompeius notes — and among the Greeks Chaos, with Thau changed into Chet; and that the names Chaos and Chohum therefore flowed from that Hebrew root. Telesius, for his part, posits two elements, Fire and Earth, which were indicated by Moses under the name of heaven and of Earth. But three elements were posited by Zoroaster, Hermes, and — if you believe Patritius, *Pancosmia* book 22 — Orpheus; likewise by Cardano, *De subtilitate* book 1; Tycho, *Progymnasmata* volume 1, page 92; and Kepler, in the *Optics* and in the *Epitome*. Therefore, if Chaos consisted of elements, according to them it was compacted of these three.

XXI. [Margin: Sixth opinion on Chaos.] The sixth Opinion, midway between the 4th and the 5th, places in Chaos only three elements, namely Earth, Water and Air, inasmuch as these are expressly set down by Moses under the names of Earth, Water and Spirit. This is the view of Cyprian the Poet, in his poem on Genesis, as cited by Ascanius Martinengus at page 272 of the *Glossa magna*, and of Claudius Marius Victor, on Genesis, in these verses:

But, to touch at once on the first beginnings of things: The vault of the lofty sky and the Earth lying below Are the first part of the work; but the wave covered the lands, And the Air in the midst, dripping with a foul cloud, And the vast abyss veiled itself in black darkness.

And Tertullian, disputing against Hermogenes, denies that there are two earths, one first unformed and the other formed, saying in chapter 31: *But for us there is one God, and one earth, which God made from the beginning*; and he adds in chapter 32: *For if the abyss is below the earth, and darkness above the abyss, then without doubt both the darkness and the abyss are below the earth. The spirit and the waters, however, lay below the Heaven; for if the waters, which had covered it, were above the earth, and the spirit above the waters, then both the spirit and the waters were likewise above the earth. And what is above the earth is certainly below the heaven; and just as the Earth lay upon the abyss and the darkness, so the heaven too lay upon*

the spirit and the waters. From this it is quite clear that by the name of spirit he understood air, or took as one and the same thing the whole of what lay between the waters and the heaven. Strabus seems to favour this in the *Glossa ordinaria*, inasmuch as among the elements that were at first mixed together he places Earth, and water throughout the whole space in which air now is, but water then mixed with air and like a thick mist — unless he also thought fire was enclosed in it. Finally, this opinion is favoured by Zoroaster, Hermes, Cardano (*De subtilitate* book 1), Tycho (volume 1 of the *Progymnasmata*, page 92), and Kepler (in the *Epitome of Astronomy* and the *Optics*), who posited only three elements, namely Earth, Water and Air.

Lastly, there can be brought back to this opinion those who placed the heaven among the 4 elements, but posited as elements distinct from the heaven only Earth, Water and Air, and yet did not take the heaven for fire: such as St Augustine, in the unfinished *De Genesi ad literam*, chapter 4; Bede, in the *Exposition of Genesis*; and Innocent III, on the 5th penitential psalm, who sets water and air confused together — I quoted their words above; and also Io. Penna the Frenchman and Christoph Rothmann, who, as Tycho testifies in volume 1, page 92, infer from the same transparency that the heaven and the aether are of the same nature as air, and hence that there are only three elements.

XXII. [Margin: 7th opinion on Chaos.] The seventh opinion seems to hold that at the beginning of the World only the highest heaven and the Earth were created from nothing, while Water and the other bodies were produced afterwards. It is the opinion of St Gregory, as will be evident to anyone who reads his whole discussion in the Commentary on Job, chapter 38. On his view, therefore, Chaos enclosed the earth alone; for the remaining heavens and the other bodies were produced from water, and water from earth, as he teaches in the same place. But this is hard to grasp. Did the earth, then, occupy the whole space that now lies between the earth and the highest heaven, and occupy a smaller space after being condensed? Or was there a void between it and the heaven? Whatever you say will run against the other Fathers and the Philosophers, and will hardly agree with the Scripture of Genesis 1, which supposes that the waters were created at once with the earth.

XXIII. [Margin: 8th, and our own, opinion on Chaos.] The eighth opinion is ours. It has as its patrons the authors of the third, and some of the second — if, as we can, we interpret them more kindly — and some of the fourth and sixth, namely if fire does not exist, or does not exist as distinct from the visible heaven; although not all those of the third opinion agree with us as regards the order. For we assert that the World was not made by God from unbegotten or uncreated matter, as some of the 1st opinion hold, for that would be heretical; nor from matter unformed or crudely formed, which was not actually earth, nor water, nor air, but only potentially, as the 3rd opinion asserts — for one thing, because that imperfection would have been utterly unbecoming to God the craftsman; for another, because Moses must not be said to have fallen short by passing over in silence, in the first chapter of Genesis, the moment or the

day on which God afterwards drew the elements out of that matter; and for another, because if at that first instant heaven and earth had existed not actually but potentially, Moses would have used other names, and would not have given the uneducated people an occasion to go astray and to understand heaven and earth in the same sense in which they are understood in Psalm 101, where it is said: *In the beginning, O Lord, you founded the earth, and the works of your hands are the heavens.* Above all, because sacred Scripture, so long as no manifest contradiction follows from the literal sense, must be taken in its proper and historical sense, the sense the letter conveys; and sacred Scripture, in Genesis 1, says that heaven and earth were created by God in the beginning, and that before light or anything else was made there was water, and spirit over the water. We must therefore understand these things, created by God in the beginning, according to their proper forms — whether fire is then indicated by the common name of spirit, or by that of heaven, or there is no element of fire at all.

For these things are not in conflict with the words *The Earth was empty and void*, or with the words *from unseen* or *unformed matter*. On the contrary, they are reconciled excellently, and without any violence, with Earth, Water, Air and Heaven complete in their substance — and this in three ways. First, on account of the lack of light, which made dark the whole depth, not only of the waters and of the earth's surface but the whole depth of the air and the aether; and so St Augustine, *De Genesi ad literam* book 1 chapter 1: *The Earth was invisible and unformed, and darkness was over the face of the abyss* — by which words he seems to signify the unformedness of bodily substance. Second, on account of the covering of the Earth, beset on every side by water, so that even if there had been light and eyes, the eyes of animals could have seen nothing from the earth, much less above it. Third, and chiefly, on account of the lack of the forms of mixed bodies, of colours, and of the other accidents and secondary sensible qualities; for that reason it was unformed and unfit to be seen, as we also explained in Question 3, from number 11 on. Nor is it any obstacle that so many Fathers were adduced for the 2nd opinion; for many of them either must or can be understood of a matter unformed only in origin and in nature, preceding the formation of the elements, not in time — as St Thomas, with St Augustine, and the followers of Augustine understood it. And once it is granted that God created the Earth, no solid reason can be brought why he did not create all the elements from nothing, whether these be three or four. [Margin: The order of the elements in Chaos.] As for the order, I hold that God did no violence to those elements, and placed them as their natural order required before they became the dwelling-place of animals: namely the earth at the bottom and middle of the world, and all the water over the earth, since the separation of the waters and their enclosure in the vessels of the earth had not yet been made; and the spirit over the waters, and the aether, that is, fire, if it exists, over the air. For in this way the Earth could be called simply both

"empty" and "Dry", if it did not even have waters within it at that first instant — in keeping with what was said more fully at number 10.

Quæſtio 6. An detur, & quando factum, & cuiuſmodi ſit cælum Empyreum?

Question 6. Whether there is an Empyrean heaven, and when it was made, and of what kind it is.

XXIV. By the name of the Empyrean heaven is understood the highest heaven of all, invisible to us in this life and without motion, within which, or upon whose surface, are and will be the Saints and the blessed Angels and men. They called it Empyrean, that is, splendid, from the most pure light with which it is believed to be endowed — although it might seem possible to render it "flaming" or "fiery", from the Greek noun πῦρ [Greek: pyr, "fire"], which signifies flame tending upwards, or fire. For it is named not from heat but from splendour, as Strabus, Hugo and the Master teach on book 2, distinction 2; or else because, just as fire is the highest of the elements, so this heaven is the highest of the heavens, as Suarez says, *De opere sex dierum* book 1 chapter 4. We have various names and descriptions of it in sacred Scripture, for our consolation and for the hope of eternal life which GOD has "promised again" — that is, promised not once but many times — to those who love him. These names will serve us as the first argument that such a heaven is distinct from the others. For Caietanus alone, so far as we know, on the 2nd Epistle of St Paul to the Corinthians, chapter 12, has dared, against the torrent of the Fathers and Doctors, to deny such a heaven, and to say that God imparts his happiness to the Blessed in no bodily place. [Margin: Caietanus alone denies the Empyrean.] For he speaks thus: *"Even to the third heaven": that is, even to the highest heaven, even to the place in which God and the Blessed are said to dwell, even to the heavenly fatherland. And he called that place the highest, third heaven, because in sacred Scripture mention is made of three heavens. The lowest is the airy heaven, according to the saying "The birds of heaven"; the middle is the starry heaven, of which it is said at the beginning of Genesis, "And he set them in the firmament of heaven"; the third and highest* is all the waters that are above the heavens, which Scripture mentions many times, and which we call the watery heaven, while the Philosophers call it the primum mobile; for the Empyrean heaven, handed down by later writers, is found nowhere in the Scriptures. From this, Vielmius says (lecture 3 on Genesis), Caietanus infers that the ancient Fathers invented the Empyrean without cause and without any compelling reason, especially since it can be detected neither by sight nor by motion, and since God, who is said to dwell in it, and the Angels are incorporeal, so that it is superfluous to assign them a place of their own. [Margin: Censure of Caietanus.] This singular opinion of his is rejected by Vielmius in that same lecture 3; by Catherinus in the *Enarratio* on Genesis, under the word *caelum*; by Ascanius Martinengus in the *Glossa magna*, from page 235, who charges Caietanus with audacity, and at

page 244 with impudent rashness; and by Suarez, *De opere sex dierum* book 1 chapter 4, who asserts that the opposite is commonly received by the Church and altogether certain. With them I shall not be reluctant to prove the existence of this heaven by the authority of very many writers, and by reasons.

XXV. [Margin: [?] Argument: the authority of sacred Scripture.] We take the first argument from Holy Writ, where such a heaven is designated and described — above all where it is called the heaven of heaven, as in Deuteronomy 10: *To the Lord your God belongs heaven, and the heaven of heaven.* And 2 Paralipomenon chapter 2: *For our God is great above all gods. Who then can prevail to build him a worthy house? If heaven and the heavens of heavens cannot contain him.* And in the same book, chapter 6: *If heaven and the heavens of heavens do not contain you, how much less this house which I have built.* And David, Psalm 113: *The heaven of heaven is the Lord's, but the earth he has given to the children of men.* And in Psalm 67, when he had said of Christ the Lord, as St Paul interprets it in Ephesians 4, *You have ascended on high*, he went on to sing: *Sing to God, who ascends above the heaven of heaven to the East.* This same heaven is called the seat of God, and his dwelling, as in 2 Paralipomenon chapter 6: *You will hear from heaven, your most firm dwelling*; for so Solomon seems there to have understood that saying of Moses in Exodus 15: *You will bring them in and plant them on the mountain of your inheritance, your most firm dwelling [?] which you have made, O Lord; your sanctuary, O Lord, which your hands have established.* And Moses himself, in Deuteronomy 26: *Look down from your sanctuary and from your lofty dwelling*; and in chapter 33: *There is no other God like the God of the most upright; he who rides upon the heaven is your helper* etc., *his dwelling is above.* For from the sanctuary — the tabernacle and the earthly temple — each of them rose to contemplate the heavenly and immovable one, that is, the Tabernacle that can never be moved; of which Psalm 32 says: *The Lord has looked down from heaven, from his prepared dwelling*; and 102: *The Lord has prepared his seat in heaven*; and Isaiah 66 and Acts 7: *Heaven is my seat, and the earth my footstool.* Nor is it the house and dwelling of God alone, but of the Elect as well, according to that saying of the Apostle, 2 Corinthians 5: *We know that if our earthly house of this dwelling is dissolved, we have a building from God, a house not made by hands, eternal in the heavens.* And it is the Jerusalem that is above, or the heavenly Jerusalem, of which Galatians 4 says: *But that Jerusalem which is above is free, which is our mother*; and of which, surely, we think it was said in Psalm 147: *Praise the Lord, O Jerusalem*, etc., *who has made your borders peace* etc.; and Psalm 112: *Jerusalem, which is built as a city, whose sharing is in itself*; and Psalm 127: *And may you see the good things of Jerusalem all the days of your life*; and Psalm 146: *The Lord builds up Jerusalem; he will gather together the dispersed of Israel*; and Tobit 13: *I shall be blessed if there remain of my seed to see the brightness of Jerusalem. The gates of Jerusalem shall be built of sapphire and emerald* etc., *and through its streets Alleluia shall be sung.* From this it is evident that he looked, in a prophetic spirit, above all to that holy City of Jerusalem which St John saw in Apocalypse 22, *Prepared as a bride adorned for her husband.*

Of this same place it is said in Psalm 67: *God in his holy place; God who makes those of one manner of life dwell in a house*; and in the same place: *The mountain in which it has pleased God to dwell; for the Lord will dwell there to the end.* Finally it is called *the Region of the living* and *the land of the living*, Psalms 114 and 142; and *Paradise*, Luke 23: *Today you will be with me in paradise*; and Apocalypse 2: *To him who overcomes I will give to eat of the tree of life, which is in the Paradise of my God* — the Paradise to which, in the third heaven, the Apostle relates that he was caught up, 2 Corinthians 12; and St Francis of Assisi used to be caught up in ecstasy on merely hearing the name of Paradise.

XXVI. The second argument is the authority of the Fathers and Doctors — [Margin: 2nd argument: the authority of the Fathers, etc.] and indeed of the ancients as well, and of very many others — besides Philo, of whom I shall speak at the end of number 30. [Margin: St Clement, Pope.] For St Clement, in book 1 of the *Recognitions*, reports from the mouth of St Peter, disputing with Simon Magus: *This visible heaven was made, which is one day to be dissolved, for the sake of the present life, so that there might be a kind of partition and division, lest anyone unworthy should by chance see the dwelling of the heavenly beings and the seat of God himself, which is prepared to be seen by those alone who are pure in heart.* And again, when Simon contended that it was better to acknowledge and proclaim one heaven in the whole universe: *Not so*, says Peter; *rather it is fitting to confess one God, who truly is, but that there are heavens, which were made by him, as the law also says: that there is one higher heaven, by which the visible Firmament too is contained; that that one is perpetual and eternal, together with those who dwell there; but that this visible one is to be dissolved at the consummation of the age.* These words are like what St Peter says in Epistle 2, chapter 3. [Margin: Anacletus.] After him Pope Anacletus says at the end of his decretal Epistle: *The Lord came from the heavenly air and the Empyrean dwelling into the most pure womb of the most chaste Virgin, taking flesh for our redemption.* [Margin: The name of the Empyrean is very ancient.] From this you see that this name was not devised by Strabus and by Bede, as Pererius thought, on Genesis book 1, page 29, and Martinengus in the *Glossa*, page 248.

[Margin: St Justin and Plato.] That this heaven was known to Plato too is attested by St Justin, in the panegyric Oration, or Exhortation to the Gentiles, in these words: *And in the same way, concerning the heaven that came into being, he thought that the heaven which was made is that which, having been made, falls under the senses; but that the other is that which is grasped by intelligence and reason; of which the Prophet says, The Heaven of Heaven is the Lord's* — as though Plato believed that the Empyrean was not made, but either created or from eternity. [Margin: Clement of Alexandria.] Moreover, Clement of Alexandria, *Stromata* book 5, thinks that Orpheus and Homer had caught the scent of such a heaven; and, expounding that saying of Isaiah 66, *Heaven is my seat, and the earth my footstool*, he adduces those verses of Orpheus about God:

He himself stands fixed and firm on great Olympus. His throne is of gold, and the earth set beneath his feet, etc.

And similar verses of Homer, but more of them, in which he describes the House of God and of the Gods. [Margin: Origen.] But Origen says it more plainly, in Homily 1 on Genesis: *God made heaven first, of which he says, Heaven is my seat; but after it he made the firmament, that is, the bodily heaven* — by "bodily" meaning visible; and in *Peri Archon* book 2 chapter 9: *This whole is called the World, in which certain things are said to be supercelestial, placed in more blessed dwellings and in more heavenly and more splendid bodies.* [Margin: St Hilary.] That the opinion about the Empyrean was common even in his own times is shown well enough by St Hilary, in the *Enarratio* on Psalm 122. For when he had said: *This heaven, which lies beneath our sight by reason of its matter, and which, as being more firmly solidified, has received both the nature and the name of Firmament, will pass away and will not be; but the seat of the Lord remains for ever*, he added not long after: *And because, according to bodily understanding, that sense is available to us, that God is thought to dwell in the heaven which is beyond the nature of this firmament, let us not exclude that public opinion concerning the seat of God, that the heaven of heaven too is his throne* etc. He also gives the fittingness of creating this heaven, in the *Enarratio* on Psalm 135, saying: *When he who is infinite set the region of his knowledge in the Higher and first Heaven, which was likewise placed round as an orb, he enclosed a certain boundary for the powers which were to be begotten first for knowing him; for the creations to be begotten could not have borne the power of the unseeable God unless, by the interposition of a more tempered nature, they inhabited this seat in measure, to suit the weakness of their measure. For by raising the waters he tempered that very nature of the first heaven, which, kindled by the power of God on high, could by no means have been endured by lower natures; but the lower heaven he stretched out not uniform but manifold, the whole of which he named the firmament; and he solidified it with a firmness strong enough to sustain the upper waters and to temper our air.* Therefore, just as the damned in Gehenna inhabit a fire, but a smoky and dark one, and a dense gloom, so on the contrary the blessed, according to St Hilary, inhabit a most bright fire, or region, but one kindled by the power of God; and perhaps the bodily eyes of the Blessed see the Divine immensity tempering itself to them under the bodily appearance of the Empyrean — granted that they see it intuitively, and in a nobler manner, by the intellect raised through the light of glory. And God is said to dwell in this heaven because by sight and face to face he shows himself to those who dwell in it, as St Augustine excellently says on Psalm 122, where he also says that the Angels themselves and the Blessed can be called heavens, because God dwells in them by sight. [Margin: St Augustine.] And he adds: *For if we have understood this bodily heaven, which we see with our eyes, to be the dwelling of God, the dwelling of God will pass away, since heaven and earth will pass away.* [Margin: Matthew 24.] Since, then, the dwelling of God will not pass away, there is another heaven, now invisible to us, which the same writer assumed in book 12 of the *Confessions*, chapter 8, when he says: *Which firmament you called heaven, but the heaven of this earth and sea, which you made on*

the third day etc. — alluding to another Heaven, which does not belong to the use and sight of the inhabitants of Earth and Sea.

But whether St Augustine, in book 10 of *The City of God*, chapter 27, meant to take in this heaven under the name of Empyrean, or the starry heaven as well, or the starry heaven alone, is not evident. [Margin: The name of the Empyrean in St Augustine.] His words, with which he refutes Porphyry for having placed demons and evil spirits above the Moon, against the doctrines of Plato, and for having been worse in this than Apuleius the Platonist, are these: *But you learned this not from Plato but from your Chaldean masters: to raise human vices into the aethereal or Empyrean heights of the World and the heavenly firmaments, so that your Gods might pronounce divine things to the Theurgists.* But I ought first to have brought forward an older Father, of the second century, Theophilus of Antioch, who says in book 2 *To Autolycus*: [Margin: Theophilus of Antioch.] *In the first place, where sacred Scripture treats of the creation, or genesis, of the World, it does not speak of this visible Firmament, but sets forth some other heaven invisible to us; the second, which is visible, has been called this firmament.* Let there follow Diodorus of Tarsus, the teacher, as they say, of St Chrysostom, on Genesis chapter 1, saying: [Margin: Diodorus of Tarsus.] *After the visible substances and those endowed with intellect, God at once fashioned heaven together with the Earth — not the heaven that can be seen, but the one that is above all the heavens, and which David is accustomed to call the heaven of heaven.* Then, in the 5th Century, Junilius flourished and wrote a *Hexaemeron*, where, speaking of the heaven made on the first day, he says: [Margin: Junilius.] *For that is the higher heaven which, set apart from every condition of this revolving World, remains ever at rest in the presence of the divine glory. For of our heaven, in which are placed the luminaries needed for this age, Scripture declares in what follows how, or when, it was made.* Next, bringing in the authority of St Jerome, he most beautifully suggests the place in which Lucifer formerly was with the Angels not yet blessed, in these words: [Margin: And in him, St Jerome.] *St Jerome too mentions the higher heaven, writing thus, namely on that saying of Isaiah 14, "I will ascend into heaven, I will exalt my throne above the stars of heaven": And he said these things both before he fell from heaven and after he fell from heaven. If he was still placed in heaven, how does he now say, "I will ascend into heaven"? But because we read, "The heaven of heaven is the Lord's", while he was in heaven, that is, in the firmament, he longed to ascend into the heaven where the throne of the Lord is — not from humility but from pride. But if he speaks these words after he fell from heaven, we must understand arrogance: that even cast down he does not rest, but still promises himself great things — to be not among the stars but above the stars of God.* Add to these words that perhaps it is for this very reason that the pride of those who hate God, that is, of the demons, is said to be always ascending: because still and always, with most obstinate desire, they persist in that old but impious and vain resolve, *I will ascend.*

[Margin: Theodoret.] An author of the same century likewise, Theodoret, Question 11 on Genesis: *Just as this Heaven is a covering for us, so the heaven which we see has another heaven placed above it as its covering.* In the same fifth

century St Prosper also was illustrious, who says on Psalm 113: [Margin: St Prosper.] *But our God is in heaven above; he has done all things whatsoever he willed above the earth — not in the heaven where those who worship the creature see the Sun and the Moon, but in the heaven above, which surpasses all bodies, celestial and terrestrial.* I come now to two authors of the sixth century, of whom the earlier, Anastasius Synaita, in book 2 of the Commentary on the *Hexaemeron*, himself also acknowledges three heavens, when he speaks thus: *But if in the hymns of David you hear also of the heavens of heavens, this is a property of the Hebrew language, which often names the singular in the plural; but when you hear that Paul was caught up to the third heaven, consider the first heaven to be the air, in agreement with what is said, "I know all the birds of heaven", that is, of the air; then the second heaven, that of the stars; and the third, the highest heaven, that of the Angels.* [Margin: Procopius of Gaza.] Almost his contemporary, Procopius of Gaza more than once, and not inelegantly, depicted this heaven for us, on Genesis chapter 1; for he says: *God had decreed to found two most beautiful works: the one subject to change and corruption, which we behold lying beneath our eyes; the other he willed to be free and empty of the stain of the evils of the present age, and into it Christ, clothed in human nature, entered first of all*; and again: *Into this splendid work we shall enter after the second glorious coming of God* etc.; and he adds that this is that inner tabernacle of which Hebrews 6 speaks. Finally he concludes: *For with Christ we shall dwell in that Heaven, mingled with the invisible powers, or virtues; and the heaven which now serves as the roof will in the end be the foundation of the highest heaven at the common resurrection; for it is the first heaven, as it were the heaven of heaven; and indeed it is not without reason that David sings: The heaven of heaven is the Lord's, but the Earth he has given to the children of men.*

[Margin: Sedulius.] Closer to both these authors was Sedulius, though somewhat older, in the *Collectaneum* on the epistle to the Romans, on the words *Hope that is seen is not hope*: *Nothing at all, then, is to be hoped for in the future from the things that are seen. For eye has not seen what God has prepared for those who love him. But the eye has seen heaven and earth. It is not fitting, then, to believe that what is seen has been prepared by God for those who love him; rather, a heaven — or rather heavens — far more eminent and lofty than the firmament that can be seen, and an Earth, are to be hoped for: not, however, this dry land that lies beneath our eyes, but that land of the meek which eye has not seen.* [Margin: Bede.] I would add Bede at this point, but the words attributed to him in *De opere sex dierum* others ascribe, together with that whole work, to Junilius, and I have already quoted them as taken from Junilius. Yet it may have happened that, just as St Ambrose compiled his *Hexaemeron* from St Basil, so Bede compiled his from Junilius; and in that case we do not lack, for the Empyrean, a fit witness from the eighth century, in which Bede lived — just as we do not lack Alcuin, on Genesis chapter 1, who in the same century asserts the same heaven. [Margin: Alcuin.] In the ninth century, moreover, St John Damascene was eminent; [Margin: St Damascene.] he observed the distinction of three heavens fully in agreement with Anastasius Synaita, and asserted in book 2 *On the Faith*,

chapter 6: *Since, then, Scripture speaks of Heaven and of the heaven of heaven, and likewise of the heavens and the heavens of heavens, and the Divine Paul asserts that he was caught up to the third heaven: we say that in the creation of this universe that heaven was founded which those who flourished among foreign peoples with the praise of wisdom, claiming the doctrines of Moses for themselves, call the starless orb.* He goes on, and a little below says: *Indeed the heaven of heaven is that first heaven which exists above the firmament; so you now have two heavens, for God called the firmament by the name of heaven. Then it is usual and familiar to Scripture to call the air too heaven, because, of course, it is seen above; for it says, "Bless, all you birds of heaven", that is, of the air: there is the third heaven.* [Margin: Strabus. Rabanus.] In the same century Strabus, in the *Glossa ordinaria*: *In the beginning God created heaven and earth; by heaven he meant not the visible firmament but the Empyrean, that is, the fiery or intellectual heaven, which is so called not from burning but from splendour, and which was at once filled with Angels.* Rabbanus [Rabanus Maurus] agrees with him, on Genesis chapter 1. Let us pass now to the eleventh century, and hear St Anselm of Canterbury, *De imagine Mundi* book 1 chapter 28: [Margin: St Anselm.] *Above the firmament is the spiritual heaven, unknown to men, where the dwelling of the Angels is, arranged by all their orders*; and soon after: *This is the heaven which is read to have been created with the earth in the beginning; far above it the heaven of heavens is said to rise, in which the King of the Angels is said to dwell.* Therefore, on the view of this Doctor, just as the starry heaven is subdivided into several heavens according to the number and order of the Fixed stars and the Planets, so the Empyrean is subdivided into several heavens according to the hierarchical order of the Saints; and the highest among them, in which Christ dwells, he calls by antonomasia the heaven of heaven; and these he calls spiritual, because of their subtlety, and because they are invisible to us. [Margin: St Bruno.] St Bruno, Patriarch of the Carthusians, in the book *De Nouis*, chapter 2: *Moses posits two heavens; for he says, In the beginning God created heaven and earth: here is one; on the second day the Lord made the Firmament in the midst of the waters* etc.: *here is the other.* He adds that this second is the one in which the stars are, and which is seen by the eyes: *For it is impossible to see the first heaven from this World*, he says in the same place. [Margin: Rupertus.] And now the Fathers of the twelfth century invite us — namely Rupertus, book 1 of the Commentary on Genesis, chapter 1, on the words *In the beginning God created heaven*: *Surely by the name of heaven that invisible fatherland of the holy Angels is designated*; and in chapter 6 he says that by those words animal men do not understand heaven, but that by them alone who can say, *But our conversation is in heaven*; *where*, he adds, *the High Priest Jesus Christ, the Son of God, who has passed through the heavens, is locally present and is locally seated according to the true body of a man.* [Margin: Hugo Victorinus.] Next, Hugo Victorinus, in the *Summa sententiarum*, tractate 2, chapter 1: *Here we do not call heaven the Firmament, which was made on the second day, but the heaven which is called Empyrean, that is, splendid, which, as soon as it was made, was filled with Angels — namely that upper part, as far as which that fabric of the elements,*

still undistinguished, extended. [Margin: The Master.] From him the Master of the Sentences copied out almost word for word, in book 2, distinction 2, so there is no reason for us to repeat it.

But, to join this century to the thirteenth, the first to meet us is Alexander of Hales, [Margin: Halensis.] in part 2 of his *Summa*, question 47, members 1, 2 and 3, where he teaches that the Empyrean is luminous, and was fittingly made for the blessed spirits as well: because the spiritual souls themselves, joined then to incorruptible bodies, require the noblest body in the universe; and between them and the spirits separated from body, which of themselves do not require a bodily place, there is nonetheless a great affinity and fittingness. He adds that this heaven has the character of a container [rationem continentis] and is at rest. From this teacher St Bonaventure drew, in book 2, distinction 2, article 1, question 1, and St Thomas, in part 1, question 66, article 3. [Margin: Saints Bonaventure and Thomas.] For since bodily glory too is awaited in the bodies that are to be glorified, it was fitting that from the beginning, when spiritual glory was begun, there should be some place incorruptible, immobile and wholly bright; and for this reason, they say, it is called Empyrean — not from burning, but from splendour. But Gulielmus Parisiensis [Guillaume d'Auvergne], who also belongs to this century, teaches the same things about the Empyrean at greater length and brilliantly, [Margin: Gulielmus Parisiensis.] in the book *De Universo*, first part, from chapter 33 to 36; and he teaches that the Empyrean was founded in the beginning of time, and is most at rest, most bright, etc.

Finally, the authors of the 14th and 15th centuries expressly acknowledge it, and that it was created in the beginning of the World: [Margin: Lyranus. Tostatus. Catherinus. Picus.] Lyranus in the *Postills* on Genesis; Alphonsus Tostatus on Genesis chapter 1 and on Exodus chapter 23, questions 52 and 53; Picus Mirandulanus [Giovanni Pico della Mirandola] in the *Heptaplus*, chapter 1, citing Abraham and Isaac, most learned Rabbis; Catherinus on Genesis chapter 1; and among the more recent, Martinengus at length in the *Glossa magna*, from page 171 and from 236. So too all our own writers who have discussed this subject or the number of the heavens, [Margin: Molina. Valentia. Suarez. Pererius. Tannerus. Salianus. Cornelius. Tirinus. Fernandius. Coimbra.] but especially Molina and Suarez, *De opere sex dierum*, book 1, chapter 4; Valentia, in the first part, disputation 5, question 3, point 1; Pererius on Genesis, book 1, from page 27; Adam Tanner, *De caelo*, questions 1 and 2, and volume 1 of his *Summa Theologica*, disputation 2, question 2, doubt 2; Salianus, in the *Apparatus* to the *Annals*, chapter 6. And so too those who have published notes or commentaries on Genesis — especially Cornelius à Lapide, Tirinus, Fernandius and, learnedly, the Coimbra commentators, book 2 *De caelo*, chapter 1, question 1.

XXVII. [Margin: 3. Argument: from Reason.] The third argument is drawn from reason — not demonstrative reason, but reason resting on most fitting persuasions [suasionibus], which come down to two. The first is the perfection of the Universe: just as in the World there are simple bodies, corruptible of

themselves and mobile, so above them there should be a body incorruptible and immobile (for it is more probable that the starry and the watery heavens are of themselves corruptible from within, as we shall show below in chapter 2); and the whole World should be enclosed between two immobile extremes, namely the Earth and the Empyrean. The second is that it befitted God, from the beginning of the World, to prepare for the bodies of Christ, of the most Blessed Virgin and of the other saints, which were to be glorified in their own time, a special bodily place, to be the kingdom and seat of the Blessed, and in which God, as on a throne, might manifest his glory to them in a special way. For just as the eternal fire was prepared as a prison of the damned for the Devil and the Angels, so in Matthew 25 it is said: *Come, blessed of my Father, receive the kingdom which has been prepared for you from the beginning of the world.* Nor, as Suarez notes in *De opere sex dierum*, book 1, chapter 4, can this be understood of spiritual glory. For that glory was prepared, as to intention, not from the beginning of the world but by predestination before the foundation of the world and before eternal times [ante tempora saecularia], as the Apostle says; [Margin: Ephesians 1.] nor, in execution, was it given to men from the beginning of the world. The passage therefore speaks of a place suited to the bodily glory of men. And indeed, who would say that the body of Christ and of the most Blessed Virgin is in no bodily heaven at all, when the Apostle so often proclaims this of Christ, and the Catholic Church of the most Blessed Virgin? Or that they are above this mobile heaven and are swept round with it? Or that they have no fixed footing in any one part of heaven? Was it not fitting that a heaven of this kind be created for the sake and honour of Christ alone and of his most holy Mother, a heaven in which their bodies were to be for all eternity — if God founded so many other mobile heavens for the use of a very brief time and for the shadow of a momentary happiness? Now if it was fitting that the Seat of Christ and of the Queen of the Heavens, and the body of all the Saints, should be in this Empyrean heaven, then the Angels too, as ministers, ought to have been in it — granted that of themselves they do not require to be circumscribed or defined by a bodily place. These are all the reasons, or the chief ones, that Alensis, Saints Bonaventure and Thomas (cited above), Pererius (book 1 on Genesis, page 29), Suarez (*De opere sex dierum*, book 1, chapter 4), Salianus (in the *Apparatus* to the *Annals*, chapter 6) and Ascanius Martinengus (in the *Glossa magna*, from page 244) give for the Empyrean.

XXVIII. [Margin: Whether the Empyrean has been from eternity.] But when was this heaven created? From eternity? Or at least long before this World and its elements? Or rather in the first instant of this World? For Steuchus, or Augustinus Eugubinus, [Margin: The error of Augustinus Eugubinus about the Empyrean.] in the *Cosmopoeia* and in the treatise *De naturis incorporeis*, dared, among other paradoxes, to say that the Empyrean is something eternal and uncreated: that is, a certain light and brightness flowing from the essence of God, in which God is; a light of the divinity which has always and necessarily been with God, and to the participation and enjoyment of which both the

good Angels and just men are admitted. For he says: "This is that light and brightness of God, and the immense light of the divinity, and something most blessed which I dare not name, which is above heaven, which is neither a place nor a body, and which is so often promised in scripture to the just as their reward." Of this light, he holds, we must understand the verse of Psalm 103, *Clothed with light as with a garment*; and Paul's words, "Who dwells in light inaccessible"; [Margin: 1 Timothy 6.] and Christ's words in John 17, "Glorify me, Father, with the brightness which I had with you before the world was made." A certain specimen of this light, he says, was displayed in the bush of Moses, Exodus 3; in the same man's face, shining from his converse with God, Exodus 34; and in the Transfiguration of Christ, Matthew 17. He confirms this opinion of his from St Basil, Homilies 1 and 2 on the *Hexaemeron*.

But this wholly erroneous opinion is refuted, indeed hooted off the stage, [Margin: Censure of Eugubinus.] by Molina, *De opere sex dierum*, disputation 3, towards the end; Pererius, book 1 on Genesis, page 28; Catherinus, in his exposition of Genesis chapter 1; Vielmius, lecture 3 on Genesis; Ascanius Martinengus, in the *Glossa magna*, page 246; Suarez, *De opere sex dierum*, book 1, chapter 4; and Salianus, in the *Apparatus* to the *Annals*, scholium to chapter 6. Catherinus asserts that it is dangerous and a manifest error; Pererius, that it is to be refuted, utterly hooted down and blotted out by everlasting oblivion — indeed, that it is a perverse and impious dogma; Vielmius, that it resembles the heresy of Arnaldus de Brixia [Arnaldo da Brescia], who admitted that something besides God had been eternal, and that there is something which is neither creator nor creature; Martinengus and Salianus judge it erroneous and impious. Suarez, however, thinks it heretical — understand, materially; for Steuchus submitted this opinion of his to the judgement of the Church, and showed himself ready to condemn it if it were condemned by the Church. But it would have been much more prudent, say Catherinus and Pererius, not to put forward so dangerous and perverse a dogma, nor to give a handle for error to those who would read his work after his death and would not come to know the censures of the Church or of the Doctors that were to be passed, or had been passed, upon it. And against him could be urged what Cato said to someone or other: *Why did you prefer to beg pardon for a fault rather than to be free of it?*

XXIX. The error of Eugubinus is refuted by the following arguments. Either he thought that this Light of the Empyrean is in reality God himself, who, illuminating the minds of the Blessed objectively through the species of his divine essence, has the name of light, and by his immensity has the name of the Empyrean heaven — for so, it seems, he is to be understood, as it seems to Daniel Malonius, on book 2, distinction 2, disputation 7. In that case he wrongly explained its specimen by the bodily light of the bush, and of the face of Moses and of Christ transfigured; and moreover he thereby denied that the Empyrean heaven was created by God in the beginning of time, against the

sense and the common authority of the Fathers and Doctors of every century from Christ down to our own, as already in number

26 we have shown. Nor was he quite consistent with himself, for he says: *Whether this light is bodily or incorporeal I would not readily say; yet I would judge it to be such as to be visible to the mind and to the eyes — such as Christ showed when his face shone like the Sun, and such as he showed to Moses in the bush.* Or he thought that the Empyrean is something really distinct from God and yet uncreated; and that is manifest heresy, against the saying of John 1, *All things were made through him, and without him nothing was made*, and against the express article of the Creed by which we believe *in God, Creator of Heaven and Earth, of all things visible and invisible*. Or this Eugubinus judged that the Empyrean is something distinct from God and created by him, but by a necessary and eternal emanation; and in this a double heresy is involved — one which holds that God acts outwardly [ad extra] necessarily and not freely, the other which holds that some creature has really existed from eternity, against the common dogma of the Fathers and against the definition of the Lateran Council in the chapter *Firmiter*; indeed against Eugubinus himself, who in the same *Cosmopoeia* tried, and claimed, to demonstrate that the World not only did not exist from eternity but could not have existed from eternity. Moreover, he seems to savour of the error of those who say that the Blessed do not see God in his own substance but a certain light flowing from the divinity — an error which Suarez attacked in the first part, book 2, *De Attributis*, chapter 7.

Hence it is clear how ineptly he adduced the words of divine scripture to prop up his fiction. For the light with which, in Psalm 103, God is said to be clothed as with a garment, and the inaccessible light which, in 1 Timothy 6, he is said to inhabit, signify metaphorically either the holy Angels, in whose minds he dwells, or the divinity itself — since God is light, and his Word is Light from Light. But it is not something bodily, like the light of the bush or of Moses' face, nor should it be called the Empyrean heaven, for that name sounds of a creature. The brightness, moreover, which the divine Word and Son of God had with God from eternity was the truth of the Divinity, in which he was coequal and consubstantial with the Father, and according to which he wished to be known as the Son of God. Or, if that light is the very light of glory, or the expressed species of God, it is something created and in time; if, finally, it is the light of the Empyrean itself — whether connatural to it or emanating from the bodies of the Blessed — it is something bodily, visible, and likewise created in time.

But neither could St Basil support this error of Eugubinus. [Margin: St Basil misunderstood by Eugubinus.] For, often disputing against the Arians for the eternity of the Son of God, he teaches that it can befit no creature to have been eternal; and so, in book 2 *Against Eunomius*, alluding to the Apostle's words in Hebrews 1, *Through whom also he made the ages*, he said: *But since all the ages are creatures of the Son, they are understood as below the generation of the Only-begotten*; and a little after: *And some now honour even the aeon [aevum] with*

the title of eternal, because it took its name from the fact that it always is, as if ἀεὶ ὤν [aei ōn, "ever being"]. *But we assert that to attest to creatures what is eternal, and to deprive the creator of this claim, is the same madness.* Granted, he did think — not absolutely, but on a certain hypothesis not improbable to him — that the holy Angels were founded, before the creation of this visible World, in a certain invisible place suffused with a certain spiritual light, that is, one so subtle that by comparison with the light of the Sun it can be called spiritual, as Theodoret interprets him, question 6 on Genesis. And he called that place eternal and perpetual, that is, incorruptible, and eternal a parte post [at the later end], as Suarez explains — in the sense in which St Paul, 2 Corinthians 5, calls the Empyrean heaven *a house not made with hands, eternal in the heavens*. St Basil's words we shall cite shortly, in the next number.

XXX. [Margin: Whether the Empyrean is older than the visible World.] Although the Empyrean was not from eternity, some Fathers nevertheless believed — not absolutely, but with suspension of judgement and as a not improbable hypothesis — that it, taken at least as the place where the holy Angels were set from the beginning of their beatitude, existed long before the creation of this visible World, as an intelligible World. For St Gregory Nazianzen, in Oration 38, which is on the Nativity of Christ, says: [Margin: St Nazianzen.] *Therefore if, for these reasons too, the intellectual World was created by him — so far as I can philosophize and weigh great things by small: after he saw the first parts of creation splendidly established, he conceived another World, consisting of matter and visible — this concretion, namely, of Heaven and Earth* etc. And in Poem 4, which ex [?] on the World:

Now there are two Worlds, of which the one is older: Another Heaven, and the tranquil seat of pious men, Visible to souls alone, and bright on every side, etc. *But the other is in flux; then at length, for things in flux, a World Was founded,* etc.

[Margin: Nicetas.] At this place Nicetas, his interpreter, who flourished in the twelfth century, says that this intellectual World was founded *not from necessity but from goodness alone, and because that good had to be propagated*. [Margin: Anastasius Synaita.] Anastasius Synaita subscribed to this view, book 1 *Hexaemeron*, calling Gregory αὐτονομαστικῶς [recte: ἀντονομαστικῶς] [antonomastikōs, "by antonomasia"] the Theologian; for he says: *In the beginning God made heaven and earth: he names heaven, comprehending at once all the heavenly and intelligent beings of the holy Virtues, and the constitutions of the intelligent World, so that you may understand that the supernal World was fabricated first, in agreement with the discourse of the Theologian, who says* etc.; and he quotes the words of St Gregory Nazianzen. [Margin: St Basil.] Then St Basil, Homily 1 of his *Hexaemeron*: *Yet it is not unlikely that before the constitution of the World there was something intelligible to secret contemplation, though not committed to writing by Moses, as being little suited to infants and to those who need milk. There was indeed a certain state superior to the generation of the World, suited, as was fitting, to those powers abstracted from the concretion of the World — prior in time, and eternal and perpetual. In it the Creator and maker of all things perfected creatures,*

a spiritual light suited to their beatitude etc. And Homily 2: *We think indeed (if there was anything before the constitution of the sensible and corruptible World) that it was in light; for neither did the dignities of the Angels* etc. *live in darkness, but they had their state in this light, most suited to them, and in spiritual joy* etc. [Margin: Theodoret.] Theodoret transcribed these words, on Genesis question 6. He also teaches, in questions 11 and 14, that the first heaven was made from nothing and before light, the later one from water and after light; and in question 3, though he does not approve absolutely of saying that the Angels were founded before the World, he does not altogether oppose it, nor does he think it offensive to pious ears, provided they are said to be created, and in some determinate place. For he says: *For the divinity alone, as being in no way circumscribed, is not subject to place*; and at the end: *Moreover, it must be known that all things that exist, except the Holy Trinity, have a nature subject to creation; and this granted, if anyone says that the troops of the Angels were founded before heaven and earth, he will not offend the word of piety.* [Margin: Junilius, or Bede.] Junilius too, or Bede, in his *Hexaemeron*, reports the opinion of St Basil and does not refute it.

[Margin: The Empyrean was not created before the visible World.] Notwithstanding all this, it is now certain that the Angels, and therefore the Empyrean, were created only in that first instant of time of which it is said in Genesis 1, *In the beginning God created Heaven and Earth*. For so the Lateran Council defined in the chapter *Firmiter*, and so we taught, with the common view of the Theologians, in our treatise *De Angelis*; and it is gathered well enough from those very passages of the Fathers by which we showed in number 26 that there is an Empyrean — especially St Hilary, Theophilus of Antioch, Origen, Diodorus of Tarsus, Junilius, Hugo Victorinus, St Anselm, St Bruno, Halensis, St Thomas Aquinas, Gulielmus Parisiensis, Rupertus and the Master — so that there is no need to repeat them here. So too teach Molina, disputation 2 of *De opere sex dierum*; Pererius, book 1 on Genesis, page 27; Suarez, *De opere sex dierum*, book 1, chapter 4; Tanner, question 2 *De caelo*, and volume 1 of the *Summa Theologica*, disputation 6, question 2, doubt 2; and Salianus, in the *Apparatus* to the *Annals*, chapter 6 — granted that Ascanius Martinengus, in the *Glossa magna*, page 249, says that Moses, as one speaking with an uneducated people, handed down only the genesis of this sensible World and suppressed the creation of the Empyrean and of the Angels. But we have already said, in question 3, that Moses spoke not only to an uneducated people but also to all the wise of the World, though he did not express or indicate all things to all, nor in the same way; for he comprehended whatever can truly and properly be understood by the name of Heaven, by each according to his capacity. [Margin: Philo.] And so Philo, certainly most skilled in the Hebrew idiom, understood him in the book *De Mundi opificio*, where, expounding Moses, he says: *"In the beginning he made" means the same as "first he made heaven"; for it is indeed consonant with reason that this came forth first in generation, since it is the most excellent of the things that have been made and consists of the purest essence; for this*

reason it has been destined as the most sacred dwelling of the Gods, both those not apparent and those perceptibly manifest — of Angels, that is, and of Men.

XXXI. [Margin: The Empyrean incorruptible.] It remains for us to indicate briefly of what nature and condition the Empyrean is, and what its functions are. First, then, we say that it is incorruptible, or at least that it is not to be corrupted [?] nor dissolved at the end of the World; for so the Fathers cited in number 26 expressly teach. They also assert that it is invisible to us who live in this life, [Margin: And invisible.] because the Firmament and the watery heaven are interposed between us and it and by their opacity shut off our view of it; or because its light is rare, as is usually said of elemental fire. Next we say that it is uncertain whether it is an altogether simple body — indeed not so much a fifth as a certain sixth essence, in no way agreeing with material things, as Abulensis puts it on Exodus chapter 13, question 53 — or rather one consisting of matter and form; [Margin: Whether, and of what matter, it consists?] and, if the latter, whether of a matter different from the elemental (as Suarez, with St Thomas, holds in *De opere sex dierum*, book 1, chapter 5) yet the same as that of the other heavens, or rather of the same matter as the elements. It is far truer, however, that it was created not from elemental matter but from nothing, and of a matter nobler not only than the elemental but also than that of the other heavens, on account of its nobler and far more excellent end; and Suarez grants in the same place that this can be said with more probability. Nor is it absurd — indeed it agrees with the perfection both of the universe and of the Blessed themselves — that it should be altogether simple, if a body can be given that does not consist of matter and form really distinct from each other; on this see more in Suarez, *Metaphysics*, disputation 13.

All add that it is immobile [Margin: It is immobile.] — not because it could not be moved by God, or is from within incapable of motion, but because in fact it is not moved, as the eighth sphere or the lower orbs are said to be moved; for it was not made to carry the stars round. And perhaps on account of this immobility, or because it is incorruptible, or on account of the perpetual stability of the beatitude of the Saints, that city is said, in Apocalypse 21, to be laid out foursquare; for a square and cubic figure signifies stability. [Margin: The figure of the Empyrean.] Granted, perhaps on account of the excellence of the spherical figure it is round, as Aversa holds in question 31, section 4, of the *Physics*, and in this is a symbol of the divinity, as St Hilary indicates in the *Enarratio* on Psalm 135 in these words: *the higher and first Heaven, likewise set round as an orb*. Granted, too, that the Coimbra commentators, book 2 *De caelo*, chapter 5, question 1, article 2, think it is in fact square on the outside. In addition, Malonius, on book 2, distinction 2, disputation 7, section 5, holds it more probable that it is a fluid body, [Margin: Fluid or solid?] so that it may serve not only the motion of the bodies of the Blessed, which will run to and fro in it like sparks in a reed-bed, but also speech and breathing, and so that there may not be, without necessity, a perpetual penetration of bodies — though he admits that these reasons are not necessary. Suarez, however, in

De opere sex dierum, book 1, chapter 5, judges the opposite more probable. For in this way, he says, what the Fathers teach is truer, namely that it is wholly immobile; otherwise, with the arrival of one body of the Blessed after another, it would become denser, and the whole would almost fluctuate with their motion; and he thinks condensation and rarefaction unsuited to an incorruptible body. Now, just as the bodies of the Blessed can by their subtlety penetrate other bodies, they can also penetrate the Empyrean, according to the Apostle's words in Hebrews 4, *Jesus Christ, who has passed through the Heavens*. For speech, that most bright air suffices with which the inner parts of the viscera will be filled, in place of excrement and nourishment; nor will there be any need of breathing. He adds that the Blessed for the most part dwell on the convex surface of the Empyrean, as the same Suarez taught of the Body of Christ, volume 2 on the third part, disputation 51, section 1 and the last.

Light is believed to be connatural to the Empyrean, [Margin: The light of the Empyrean: of what kind?] granted that it is increased beyond belief by the light diffused from the bodies of the Saints, and above all of Christ, according to Apocalypse 21: *And the city has no need of Sun or Moon to shine in it; for the brightness of God has illuminated it, and its lamp is the Lamb.* Its light, however, does not reach us, [Margin: Why is it not seen by us?] whether because it is blocked by the opacity and density of the interposed watery heaven or of the supreme Firmament, as Ascanius Martinengus, with Basil, Ambrose, Theodoret and others, judges in the *Glossa magna*, page 249; or because it is of too rare a substance, or because that light is not proportioned to our eyes on account of its excessive splendour, as St Thomas thinks, part 1, question 66. For excessive distance, or the resistance of the waters that are above the heavens, and similar causes, which Richardus de Mediavilla adduces on book 2, distinction 2, and other Scholastics in the same place, do not seem sufficient — especially since the bodily eyes of the disciples saw the light from the face of Christ in the transfiguration, and that light ought not to be called spiritual absolutely, but only by comparison with the light that resides in dense bodies.

But does the Empyrean exert an influence on these lower things? [Margin: Whether the Empyrean exerts an influence on these lower things?] The affirmative answer is thought more probable by St Thomas, part 1, question 66, article 3, reply to 5, and in Quodlibet 6, question 11, article 19, retracting his earlier opinion; by Caietanus on that article 3; Durandus on book 2, question 2; Aegidius on book 2, question 2, article 4; Argentinas on book 2, question 2, doubt 1; Richardus on book 2, distinction 2, article 3, question 3; and Suarez, *De opere sex dierum*, book 1, chapter 5. Not that action is necessary to it in order that it be the place containing and conserving the heaven immediately subject to it — for that it suffices that it contain it and have no active qualities contrary to its qualities — but because every body naturally has some active power; because for the unity of the Universe some subordination is required, and an influence of the higher on the lower; and finally because, since the other heavens are moved, the stable diversity of colour, of inclinations and of complexions found

in the various regions of the earth seems unable to be referred to anything other than the different regions of the supreme immobile heaven, of which kind the Empyrean is. The contrary seems to me more probable, because the Fathers speak of it as of a heaven having no commerce or communication at all with natural things, and created for no other end than the supernatural beatitude of the Saints; and all that diversity among the regions of the earth is to be attributed to the different temperament of the soil. So Alexander of Hales holds of this heaven, part 2 of the *Summa*, question 47, member 1, and formerly St Thomas, on book 2, distinction 2, question 2, article 3; and before them Procopius of Gaza, on Genesis chapter 1, when he said: *The first heaven, indeed, on account of its immense remoteness, was in no way commensurable with the earth; therefore no part of it could have aided the earth's countless births.* Finally, many Fathers teach that the Sun and the stars were made on the fourth day for this reason: that it might be evident that the shoots of the earth do not depend necessarily on the stars but on God alone. But if the Empyrean naturally influenced these things, then for the same reason it ought not to have been created at the beginning.

Before we conclude this question: to some it does not seem improbable that either the Empyrean or the watery or crystalline heaven is a mirror [Margin: Whether the Empyrean has the colours and forms of the Earth?] in which all the most beautiful things that now delight the eyes of men on earth are represented in a more eminent manner and in far more vivid colours; and that this is perhaps signified in Apocalypse 21 by the jasper, the crystal, and the colours and appearances of other gems and stones, so that the eyes of the Blessed may not be deprived even of this charm and delight; and that it is in this way that a new heaven and a new earth are said to be created. Indeed Eusebius, book 11 of the *Praeparatio Evangelica*, chapter 19, thinks that there is no mixed body pertaining to the beauty of earth and sea that will not exist in that Land of the living, reserved as an inheritance for the meek, there expressed in better forms or painted in nobler colours; and he adduces the authority of Plato, speaking in the person of Socrates, who describes such a land of the blessed. But perhaps these are the dreams of men unable to tear their senses and imagination away from the figure of this world, which passes away.

Quæſtio 7. Quid fuerit Lux à Deo primo Die Mundi facta.

Question 7. What was the Light made by God on the first Day of the World.

XXXII. On that first day on which GOD created Heaven and Earth, when darkness was upon the face of the Abyss, *God said, let there be Light, and light was made.* [Margin: The light of the first day: bodily or spiritual?] In Hebrew it reads *Iehi Or, Vahc [?] or*, that is, "let there be light, and there was light"; or, as the Vulgate better has it, "let light be made, and light was made"; and the Seventy translators agree: γενηθήτο φῶς, καὶ ἐγένετω φῶς [recte: γενηθήτω φῶς, καὶ ἐγένετο φῶς] [Greek: "let light come to be, and light came to be"]. According to St Augustine — book 11 of *The City of God*, chapters 7 and 9;

book 1 of *De Genesi ad litteram*, chapters 3 and 9; book 22 *Against Faustus*, chapter 10; and often elsewhere — this light was spiritual, that is, the angelic nature. For on the one hand the Angels were created before those morning stars came to be which, in Job 38, are said to have praised the Lord while all the Sons of God shouted for joy; and their creation was indicated by Moses under no other name more fitting than in [?] that of light, since it was certainly not omitted. On the other hand, if it had been material and bodily light, it would either have been deferred to the 4th day, on which the stars were made, or else the Sun would have been created on the first day; but both of these are false. St Jerome seems to have agreed with this view on Psalm 46 — but allegorically — and so do Eucherius and Bede on Genesis, St Isidore in book 1 of *De summo bono*, chapter 10, and the ordinary and interlinear Gloss; and most constantly of all Rupertus [Rupert of Deutz], book 1 on Genesis, chapter 10, who adds that it was not fitting for that light to last only three days, since Moses is describing the production of permanent things. For the others cited above — as also Hugo in the *Summa sententiarum*, tractate 3, chapter 1; Halensis, part 2, question 49, member 1; the Master of the Sentences on book 2, distinction 13; and St Thomas in the *Disputed Questions*, question 4 — rather refrain from rejecting that opinion than approve it.

But the common view of the Fathers and Doctors is that it was bodily light, as Pererius teaches from them, book 1 on Genesis, page 45; Ascanius Martinengus in the *Glossa magna*, from page 470 to 490; Suarez, book 2 of *De opere sex dierum*, chapter 1; and Tanner, volume 1 of his *Theology*, disputation 6, question 2, doubt 3. For the literal sense demands it; and this is that light which was set against the darkness pre-existing over the face of the abyss, and which God, by dividing it from the darkness — that is, by assigning each of them a distinct time in which it should pass over the hemisphere of the earthly paradise — made into those three visible days, as patterns for the remaining days of our sensible time. Moreover, the reasons the Fathers adduce for light's having been made by God most fittingly first of all things hold only of bodily light. Namely: light is the first active quality, common to the higher and the lower bodies, and necessary for everything else to be rendered visible; but God had decreed to produce the plants and herbs, and to make the earth and the seas conspicuous, before the Sun and the Stars, *so that from things invisible visible things might be made*. [Margin: Hebrews 1.] Next, God wished to show that all that light which makes the day for us, measures the times by the motion of the Sun and Moon, and is the universal ornament of the Heavens and the elements and the vehicle of the species and of the influences, does not depend essentially on the stars, and therefore that the stars are not to be worshipped with divine worship; and for this it was required that it be of the same species as the light which he afterwards granted to the Sun and the Moon, as to servants carrying torches before God for the world. Finally, the Church presupposes this very thing in the hymn for Sunday Vespers, when it says:

Best Creator of the light, Bringing forth the light of days, Preparing, with the first beginnings of new light, The origin of the World; Who bid the morning, joined to evening, Be called day.

XXXIII. [Margin: Primordial light: was it Fire?] But what, then, or what kind of thing was that bodily light? That it was Elemental Fire which, separated out from the other elements as the lightest of them all, lit up everything, was the view of St Gregory of Nyssa in *On the History of the Six Days*; of Hermes, as cited by St Cyril, book 2 *Against Julian*; of St Damascene, book 2 *On the Faith*, chapter 7; and nearly that of Alcuin on Genesis and of Hugo, chapter 6. But elemental fire is judged too rare to be fit to illuminate and constitute the day. [Margin: Or a bright Cloud?] Others say it was a bright cloud, or something similar, set up either in the East or in the Meridian of that Horizon in which Paradise later lay, and that it played the part of the Sun. So Strabus in the ordinary Gloss; Hugo Victorinus; Richardus Victorinus [Richard of Saint Victor], book 1 of *De sacramentis*, chapters 9 and 10; Hugo Carensis [Hugues de Saint-Cher] in the *Postills*; Petrus Comestor, chapter 3 of the *Historia scholastica*; Lyranus in the *Postills*; Tostatus; the Master on book 2, distinction 13; St Bonaventure on book 2, distinction 13, article 1, question 1; and Alexander of Hales, part 2, question 46, member 1. [Margin: Or the Sun?] Others have said that it was the Sun, but without a determinate power for particular effects, or without the full density and figure of its globe, and endowed with only a little light: so St Thomas, part 1, question 67, article 4, adding St Dionysius the Areopagite, and question 70, article 1, reply to 2; Vielmius, lecture 10 on Genesis; Aegidius, part 2 of the *Hexaemeron*, chapters 5 and 6; Carthusianus on Genesis, article 9; Pererius, book 1 on Genesis, page 49; Valentia, disputation 5, question 3, point 1; and Suarez, book 2 of *De opere sex dierum*, chapter 2. [Margin: Or the Sun, with the motion of the primum mobile alone?] Or else the Sun indeed, but flashing with a fuller splendour than it does now, as Steuchus holds in the *Cosmopoeia*; or the Sun shining just as it did afterwards and does now, but moved at that time only by the motion of the primum mobile, and afterwards, from the fourth day, receiving its proper motion together with the other planets. [Margin: Or a splendour of the Empyrean?] Others hold that it was a splendour placed in the Empyrean, as St Bruno hints in the book *De novis*, chapter 2, and Gulielmus Parisiensis in the first part of *De universo*, chapters 40 and 41 — a view that greatly pleased Halensis, part 2, question 45, member 2. Others again hold that it was indeed the light of the Sun, but not yet joined to its globe, and implanted in it afterwards on the 4th day; and very many, who are to be cited below, have in fact thought so. This opinion especially pleases Molina, disputation 7 of *De opere sex dierum*; Eugubinus, book 7 of *De perenni philosophia*, chapter 8; Tanner, volume 1, disputation 6, question 2, doubt 3; and Salian in the *Annals*, at the 1st day of the world; and it appeals to me greatly — provided we say that that light was of the same species as the light of the Sun, and was sustained by the heaven and the air as by a subject, rather than that it was the same light in number. For in this way it is explained according to the letter how light

was made on the first day, but not the Luminary or the Sun; and on the fourth day the very globe of the Sun, which produced, dependently on God, light of the same species — light of a species that God alone had produced before, by himself or through an Angel, varying it in the same way as the Sun now does. For whatever the Sun does now, God alone could do, drawing that light successively out of the potency of the diaphanous bodies. Indeed Scripture here uses separate and different days and names. So light was made on the first day and the vehicle of light on the fourth, as St Basil puts it — or the lamp [lychnus], as Procopius says; and the Church certainly seems to hold this when, after those verses of *Lucis creator optime*, it sings:

Most holy God of heaven, Who paint the bright centre of the Pole With fiery brilliance, Enhancing it with comely light; Who on the fourth day, setting up The flaming wheel of the Sun, etc.

The reason why God alone willed to produce that very light — that is, light of the same species that he afterwards granted to the Sun to propagate — is the one we have already indicated: namely, that men should be turned away from idolatry, and from offering divine worship above all to the Sun. [Margin: Saints Chrysostom, Basil, Ambrose, etc.; St Dionysius the Areopagite.] This reason, above the rest, is touched on by St John Chrysostom, Philo, St Basil, St Ambrose, Severianus and Procopius, chapter 4, question 1, who are to be cited later. Nor does St Dionysius the Areopagite stand in the way, in the book *On the Divine Names*, chapter 4; for his words, faithfully rendered from the Greek, are these: *Light is the measure of the hours, of the days and of all passing time; for it is that very light — although it was then formless, in Greek* φῶς ἀσχημάτιστον [Greek: phōs aschēmatiston, "shapeless light"] — *which, as the divine Moses also says, defined and distinguished that first triad of our days.* So he holds that it was light of the same species as the Sun's light of today, and he calls it formless, or lacking figure, because it was not joined to any body having the determinate figure of a luminary. [Margin: St Gregory Nazianzen.] St Gregory Nazianzen says the same thing in clearer words, oration 43: *To the lower things* etc. *he imparted the first force of this luminary (for it was fitting that the Great Light should begin his work from light), by which he dispelled the darkness and that vast heap of things and the confusion that filled everything. Nor did he bring it forth bound to an organ from the beginning, nor — in my opinion at least — as solar, but without body and without Sun* — in Greek it reads ἀσώματον, καὶ ἀήλιον [Greek: asōmaton kai aēlion, "incorporeal and sunless"] — *and afterwards it was handed over to the Sun to illuminate the world. For since in other things he had kept to this order, first to found the matter and then to adorn it with form — order, that is, and figure and bulk being imparted to each thing — here, to give a specimen of some greater miracle, he brought forth the form before the matter (for light is the form of the Sun), and afterwards introduced the matter, fashioning this Sun, the eye of the day.* Here he recognises a miracle at least in this: that God alone produced light, the form of the Sun, before its own primary matter. For light is primarily in some luminous and opaque body, by which it is both sustained and produced, and from there it

is propagated into a secondary subject, which is the diaphanous body through which it is transmitted, such as air and water. In this sense I admit that that light was created by God independently of a sustaining subject — that is, of the primary subject — and without the concurrence of the air and the heaven producing it, granted that it was sustained by the air, the heaven and the water. For no greater miracle was needed for the end God had set himself, and we ought not to multiply miracles without necessity. [Margin: Miracles are not to be multiplied without necessity.] As St Augustine rightly says, book 2 of *De Genesi ad litteram*, chapter 1: *For it is now fitting for us to inquire how God instituted the natures of things according to his scriptures, not what he might will to work in them or out of them as a miracle of his power.* But scripture says: *God said, Let light be made* — the formula he used when he did not create in the proper sense, but from mat- ter or in matter produced something; therefore he created light neither properly nor absolutely, but relatively to its own subject. In this sense I accept that it was an accident subsisting without a subject. Nor do those words of St Basil bind us to anything else, in homily 2 on the *Hexaemeron* [Margin: St Basil.]: *The first word of God created the nature of light, dispelled the darkness, and lit up and gladdened the world*; and in homily 6, speaking of the Sun made on the fourth day: *These things are certainly not opposed to what was said above about light. For then the very nature of light was produced, whereas now the body of the Sun was founded, to be a vehicle for that primordial light,* etc. *And lest what I have said seem incredible — namely, that light and splendour are something other than the body that underlies the light and is its subject: all composite things are usually divided into the substance that receives and the quality that befalls it. So, just as whiteness and the whitened body are different, so too the things we have just spoken of differ, though they are united by the power of the Creator. So do not tell me that it is impossible for light to be separated from the body of the Sun. For I do not say that the separation of light from the body of the Sun is possible for me or for you; but I judge it must be asserted that things which can be disjoined from each other by the mind's thought alone can in reality be separated by the power of him who created both natures.*

[Margin: Theodoret.] Theodoret too speaks most beautifully to our point on Psalm 148. Weighing the verse *Praise him, Sun and Moon; praise him, all you Stars and Light*, he does not approve the version of Symmachus, who renders it *Stars of light*, as though the Stars were the same as light, or the principal causes of light; and he says: *Yet according to the Seventy it is to be understood thus. On the first day God made light, but on the fourth the luminaries; and for this reason the Psalmist made separate mention of light — not because it subsists by itself, but because it was assigned to the luminaries.* And in question 14 on Genesis, distinguishing creation taken in the broadest sense from creation taken strictly, he says: *The Lord God is accustomed to create both out of things that are not and out of things that are; for the earlier heaven he created out of nothing, but the later he made out of water,* etc. *Therefore he also created light as it pleased him,* etc., *and, distinguishing that light at his own will, he founded the luminaries great and small.* [Margin: St

Athanasius.] St Athanasius also teaches that that light was distinct from the body of the Sun and was founded first, and then gathered and assigned to the luminaries — question 83 on Genesis, at the words *Let light be made*, where he says: *That light is not the Sun. But hear what kind of light it is: this light is that morning light which rises at dawn and illuminates the world before the Sun rises. Since this light was great and most splendid, God divided it into those luminaries, the Sun and the Moon,* etc.; and in question 85: *That great light which God had made he divided into the Luminaries; and this light, scattered or distributed here and there, was to some extent diminished. Had this not been done, living creatures could not have borne the great radiance and splendour of so great a fire.* [Margin: St Ambrose.] St Ambrose urges the same distinction of light from the substance of the Sun, book 1 of the *Hexaemeron*, chapter 9, explaining from it how light was produced by God first and the luminaries afterwards: *The light of day is one thing, the light of the Sun and of the Moon and of the Stars another*; and he proves this from the light of Dawn, which makes the day without the presence of the Sun. [Margin: St Augustine.] And St Augustine, book 1 of *De Genesi ad litteram*, chapter 11, having raised the Question *Why then was the Sun made to rule the day, to shine upon the earth, if that light had been enough to make the day, which was also called day?*, answers that perhaps the Sun was made to illuminate the lands, since that first light perhaps illuminated only the higher regions; and then he adds: *This too can be said: that the brightness of the day was increased by the addition of the Sun, so that the day may be believed to have been less bright through that light than it is now.* For he is alluding to the words of Psalm 135, *The Sun to rule the day, the Moon and the Stars to rule the night* — or "for governance", as St Chrysostom reads it in homily 6 on Genesis: *That is, so that the Sun may make the day brighter with its rays*, as he himself says. [Margin: Procopius of Gaza.] Procopius of Gaza, too, speaks excellently on our side, book 1 on Genesis, and at length; but it is enough to have pointed out these words: *First light was brought forth by the intervention of the divine voice; then at last the receptacle of light was founded. For it is as fire is one thing and the Lamp another. For of the light that lacks matter the Sun was made, as it were, the body; since composite things, too, are divided into the subject and the quality that inheres in the subject.* He then shows that the power of God is so great that it can produce effects and qualities without substances. He confirms this both from the fire in Moses' bush, shining and not burning — for there the splendour was separated from the heat or from the heating, and the words of Psalm 28 were fulfilled, *The voice of the Lord dividing the flames of fire*; and he adds that perhaps, in the opinion of some, the fire is to be divided on the last day, so that the fiery Light is given back to the godly while the force of the fire, which burns, is assigned to the ungodly — and, finally, he calls the light of the Moon, now full, now waning, a quality.

[Margin: The other Procopius.] The other Procopius, however, in his commentaries on Genesis, chapter 1, says: *God, taking the purest part of the primordial light, transferred it into the Sun; the remaining part he distributed among the Moon and the remaining stars.* [Margin: Apollinaris.] Apollinaris holds this

too. Nor is the view of Iunilius on the *Hexaemeron* to be scorned. At the words *Let light be made* he teaches that that light was produced in the waters and the abyss of waters, which he thought then reached right up to the Empyrean; and that it is no wonder if light shines in water, since oil poured from the mouths of those who swim under water shines back in the water before their eyes. And at the words *Let them be for Signs and times* he adds [Margin: Iunilius.]: *For that whole three-day period had passed in an undivided progress of its course, with no measure of hours at all, since the primary light still filled everything in general and had no head — which it now has received from the Sun — and nowhere had more burning rays shone.* [Margin: Tertullian.] Tertullian also presupposes that light was made before the sun, in the book *Against Hermogenes*, when he says: *For he did not at once fill the light with the splendour of the Sun, nor at once mark the heaven with constellations and stars,* etc. Various poems of the Fathers on Genesis, and Sibylline verses, could be adduced; but, so as not to run on too long, I refer the reader to Ascanius Martinengus in the *Glossa magna*, from page 482. On page 488 he plainly agrees with us: namely, that that light was produced without the globe of the Sun, and the Sun only on the fourth day; and that light is called in Hebrew *Or*, but the Sun *Moor*; and by the distinction of these names and days he indicates the diversity of the things produced clearly enough. [Margin: Burgensis.] Burgensis also favours us, in his *Additions* on Genesis, where he notes that what was said was "let there be light", not "luminary"; that a bright cloud is not light but a luminous body and a luminary, and that what Moses expressed was therefore a quality without a substance; further, that if that light had been in the substance of the Sun, it ought to have been said "let the Sun produce light", just as, because the earth and the water existed, it was said in Genesis 1, *Let the earth bring forth grass, and let the waters bring forth the creeping thing*. And he observes most acutely that on the fourth day it was said to the luminaries that they should divide the light from the darkness, whereas on the first day this was not said, because they had not yet been made, but God himself divided the light from the darkness. In this, however, he dissents from us: he thinks that that light was of a different species from the light the Sun now produces, because he thinks it unfitting that the light of the Sun should then have been without its subject, and before its subject. But he does not notice that this goes against many of the Fathers already reviewed, who teach clearly enough both that it was of the same kind and that it was created, or produced, by a miracle of God alone, without the Sun sustaining and producing it. But, you will say with Pererius, the first day, on which the World was created and which the Church calls the Lord's day, was called the day of the Sun by the ancients; so it is a sign that the Sun existed on that day. Martinengus, however, replies that this is a very weak argument, since the day was called the Sun's by the heathen out of superstition or astrological vanity — the same from which they also called the Sabbath the day of Saturn; and yet Pererius would not grant that Saturn was made on the last day of that first week, on which God rested

from his work — and that the first day was ascribed to the Sun on account of its primacy in light.

Quæſt. 8. De diſcrimine trium primorum dierum à noctibus, ex illis verbis : Et diuiſit lucem à tenebris; appellauitq. lucem Diem, & tenebras noctem; factumq. eſt veſpere & mane dies vnus.

Question 8. On the distinction of the first three days from the nights, from the words: And he divided the light from the darkness; and he called the light Day, and the darkness night; and there was evening and morning, one day.

XXXIV. Day in Hebrew is called *Iom*, from the verb *Ham*, which means to make a noise — from the noise to come; Night, by contrast, is called *Hiela*, either from horror or from weariness after the day's waking, from which the night restores us, bringing back *sleep and the weary silences to the lands*, as Flaccus sings. Evening is called *Hareb* or *Ereb*, from *Harab*, which means to connect — that is, the day with the night; and morning, finally, is called *Boer* or *Boquer*, from the verb *Bacar*, which means to discern. With this premised, I suppose that the dark- ness that was over the face of the abyss preceded the primordial light not only in origin, or as it were in nature — as St Bonaventure maintains, as a problem, on book 2, distinction 13, article 1, question 2 — but also in duration, as St Thomas, with the common view of the Fathers, presupposes in part 1, question 74, article 3, and indeed in question 66, article 2, and on book 2, distinction 13, question 1, article 4. [Margin: Darkness prior in time to light, and everywhere.] Nor do I think it probable, whatever Suarez says in book 2 of *De opere sex dierum*, chapter 2, that it was in one hemisphere only — say, that of Palestine; rather, it was simply over the whole face of the abyss. [Margin: Was there time before light?] Further, I suppose that that whole duration up to the production of light can be called time, even if perhaps there was then no motion at all — neither of the waters, nor of the spirit borne over the waters, nor of the Sun, not yet founded, nor of the heavens. For there was a privation of that light which afterwards made the day, and it could be measured by time: just as that stay of the Sun made at Joshua's command was time, even though it could not actually be measured by the motion of the Sun. How long it lasted, however, is uncertain. Some say it was of 6 hours — namely those who think light was made at noon of the first day; others of 12 hours — namely both those who judge that light was first made on the eastern horizon of Palestine or of the earthly Paradise and those who say on the western horizon. For most of the more recent doctors suppose that that first artificial day was Equinoctial, and so of 12 hours, just like the night. [Margin: That light in a single hemisphere.] Finally, I suppose that the primordial light was not produced so as to illuminate the whole globe of lands and waters in a single instant, but only a single hemisphere of it — granted that Anastasius Synaita said: *The light of the three preceding days, expanded and dispersed through the whole*

universe, shows that the light of the uncreated Trinity reaches everywhere and leaves no place empty of it — unless you understand this of its successive propagation, by force of which no hemisphere was empty of light during those three days, as most of the Fathers understand it. For in this way it is better explained how God at once divided light from darkness, namely by place or subject and by time: he produced that light in a hemisphere different from the one where the darkness was, and willed that light and darkness should be in the same hemisphere at different times. With these points laid down, let us dispatch more briefly the principal doubts, and those more welcome to Astronomers.

XXXV. [Margin: Light produced in the upper hemisphere of Palestine.] I say, *first*, that that primordial light was produced not in the lower hemisphere of Palestine, or of the earthly Paradise that was to be founded later — as Hieronymus ab Oleastro held, and Catherinus in his exposition of chapter 1 of Genesis, who places it, or the Sun, as produced on the first day at its setting, so that the natural day should begin from the onset of night, that is, from evening — but in the upper hemisphere, as the one in which human life was to be first, and in which Christ was later to work salvation, as in the middle of the earth. For that this hemisphere was illuminated first is taught by Iunilius and Bede on the *Hexaemeron*, Comestor, chapter 3 on Genesis, Strabus in the ordinary Gloss, Abulensis on this passage, Molina, disputation 1 of *De opere sex dierum*, and Salian at the first day of the world. I said "of Palestine", or of Canaan, on account of Christ and of most of the Patriarchs and Prophets, which Molina, Tostatus, Martinengus and Salian also suppose — granted that St Augustine, book 1 of *De Genesi ad litteram*, chapter 10, and Suarez, book 2 of *De opere sex dierum*, chapter 3, number 12, seem to indicate that it was done in the land in which God was going to make Adam, or Paradise; while Steuchus places it in Armenia, Chaldaea and Mesopotamia, where the first men lived before and after the flood.

[Margin: That light applied successively to different horizons.] *Second*, I say that that alternation of days and nights took place with some succession. For what Iunilius seems to mean on the *Hexaemeron*, at the words *let them be for signs and times*, cannot stand, when he says: *For that whole three-day period above had passed in an undivided progress of its course, with no measure of hours at all, since the primary light still filled everything in general and had no head,* etc. — *no shadow was cool under rock or tree.* For granted that there was no gnomon to cast a shadow, no one to divide the day into hours, and no local motion of the light taken in the proper sense — for that, I think, is what he meant — still the time of night followed the day, nor was it day everywhere throughout those three days, as Iunilius himself had conceded earlier, and as I shall show below at number 36. Otherwise, how would God have divided light from darkness? Or how would the first, second and third day have come about from evening and morning? [Margin: Whether that succession [?] was by the local motion of the Sun or of the cloud [?]?] That succession, however, was not brought about by the local motion of the Sun or of a bright cloud, as those teach who said the

primordial light was the Sun or a bright cloud. For we have shown that that light was no such thing, granted that those Authors, consistently, teach this in the same places that we noted already at number 33. But among them Aegidius is singular. [Margin: The first day [?] shorter than [?] the 2nd and 3rd [?], and these than the rest.] He says that the first day contained only one revolution, as great as that of the primum mobile is now; that on the second and third days the Sun, besides the revolution of the primum mobile, was moved by as much as the proper motion of the Fixed stars, or of the Firmament now made; and finally that on the fourth day and after it made as much as the Sun's diurnal motion toward the East now requires; and so that the first day was somewhat shorter than the second and third, and these than the fourth and the rest. Martinengus, page 518 of the *Glossa magna*, indicates that this is fictitious; but it is certainly not improbable. St Gregory of Nyssa, on the other hand, since he judged that that light was a fire which by its lightness had been separated from the mass of the elements, held that those three days were completed by the rotation of the fire. [Margin: Whether by [?]traction and diffusion of the rays [?]?] Others explain that alternation by an alternating emission and contraction of light: namely St Basil, homily 2 on the *Hexaemeron*; St Damascene, following the teaching of Nazianzen, book 2 of *The Orthodox Faith*, chapter 7; Procopius of Gaza, chapter 1 on Genesis; and Burgensis on chapter 1 of Genesis. But St Bonaventure rejects this, on book 2, distinction 13, article 1, question 2; indeed St Augustine, book 1 of *De Genesi ad litteram*, chapter 10, fears that if this were said it would seem ridiculous. For he thinks it follows from this opinion that the day was on one Horizon only and persisted there with unmoving light for some hours, say 12, and then night in the same place for as many other hours; and, next, that no reasonable cause can be brought for such a contraction and emission, and no example. Yet the authors already mentioned can be brought round to the following opinion, which posits a successive diffusion of light; for they seem chiefly to have wished to exclude a succession of days and nights produced by the motion of the Sun. St Basil says there: *Night is the shadow of the earth, which follows the day when the Sun hides itself. Then, however, there came about a day, and night in turn followed it as it gave way — not according to the motion of the Sun, but as that primordial light diffused its splendour and drew it back again, and that by a measure defined by God.* Procopius, adhering to him, transcribes his words, adding only that that light was poured round on every side; and Burgensis, reporting the same doctrine of St Basil, adds: *This light indeed did not have motion of itself, and so could not of itself divide light from darkness, but did this through the emission and contraction of light by divine power.* St Damascene, however, says: *In those three days, by the light being poured out and drawn back, day and night came about by divine command.*

XXXVI. [Margin: Whether by successive transfer equivalent to the local motion of the Sun?] *Third*, therefore, I say that that alternation took place successively according to one Horizon after another, through a transfer or transfusion equivalent to local motion. For that division of light from darkness

was such that not only did light make and represent day, and darkness night, but also such that Morning followed Evening — a manner of speaking that signifies, in the proper sense, a day in the way it happens now, except for the Sun and the shadows bounded by the Sun's rays: God, that is, producing the daylight successively in the same way as the Sun now produces it. [Margin: St Augustine.] St Augustine indicated this, book 1 of *De Genesi ad litteram*, chapter 1, when he said that it happened then as now, so that when it was day in Palestine — that is, when day was beginning — it was still night in Africa: *That at the time when it is night with us, it illuminated with the presence of light those parts of the world through which the Sun returns from its Setting to its Rising; and that in this way, through all twenty-four hours, there was never lacking, around the circuit of the whole round, day in one place and night in another.* [Margin: St Justin. Strabus.] That those days were like ours, the Sun excepted, St Justin teaches, question 62; for he says of that light: *Days of the kind it now makes with the star of the Sun, such it made also before all the stars were founded.* Strabus agrees as well, in the ordinary Gloss: *As the light gradually set and, after the space of a day's length, went under the lower parts, evening came about, as now usually happens by the accustomed circuit of the Sun. And morning came about as the same light returned above the earth and began another day; and one day of twenty-four hours was completed.* [Margin: Hugo Carensis.] Next, Hugo Carensis in the *Postills* expressly affirms that by that light, carried round in the manner of the Sun, the upper and the lower hemisphere were illumi- nated. [Margin: Iunilius.] And before these two Iunilius did so too, in his *Hexaemeron*, adding: *He preferred to say "evening and morning" rather than "night and day were made", to suggest that the circuit of the primary light was then carried out as it is now established to be carried out, day and night, by the circuit of the Sun.* But he very shrewdly observes that in that three-day period the nights were darker than now, because the other stars, which usually temper the shadow of night, were missing, and the parts of the air lying outside the shadow of the earth were not lit by the Sun, as they are now lit even at night. So he goes on: [Margin: The three first nights very dark.] *This alone is evident: that after the stars were created, night too is suffused with a light of its own, though less than the day's; but in that first three-day period it remained dark and utterly obscure.* [Margin: Caietanus.] Most clearly of all, Caietanus on Genesis: *If the light had been fixed, then the day would have been fixed and perpetual in one hemisphere, and night continual in the other hemisphere; nor would there ever have been an evening ending the artificial day. Hence, from the fact that there was an evening ending the artificial day, and a morning ending the night, it is clearly signified that the light was made in motion; for evening comes about, and morning comes about, from the continuous motion of the light around the earth.* But if he means a local motion of the light, by which an accident would migrate from subject to subject, he multiplies a new miracle without necessity, and one of a kind that does not happen now. Therefore, just as now one light after another, numerically distinct, is produced by the Sun along straight lines, so then it was produced by God, through mere successive production rather than

through local motion. And so with us are Salian, at the 1st day of the World, and Tanner, volume 1, disputation 6, question 2, doubt 3, number 11.

Quæſtio 9. An Dies Nocti præceſſerit, An Nox Diei.

Question 9. Whether Day preceded Night, or Night Day.

XXXVII. [Margin: 1st opinion, giving precedence to Night.] We must repeat what we said in book 1, chapter 24: the ancients, and those more expert in the Latin tongue, called the Natural Day the stay of the Sun above the Horizon, which is distinguished from night, and called the day composed of light and darkness, or night, the Civil or legal day; but most of the more recent Astronomers and interpreters of sacred scripture call the Natural Day the one composed of light and night, and call the stay of the Sun above the Horizon the Artificial Day. With them, as being by far the more numerous, we shall speak from here on.

With this premised: that the Natural Day — evening being taken as the beginning of night — began from evening at the first beginning of the world was held long ago by the Manichaeans. [Margin: Manichaeans.] Of them St Augustine, book 1 of *De Genesi contra Manichaeos*, chapter 10, at the words *and there was evening and there was morning, one day*, reports as follows: *And here the Manichaeans cavil, thinking it was said as though the day began from evening.* [Margin: Thales.] The opinion also has as supporters Thales of Miletus, who, asked which came first, day or night, answered that night had come first; [Margin: Abulensis. Molina. Fernandius. Salian. Tirinus.] likewise Abulensis and Fernandius in their commentaries on Genesis at the words *and there was evening and morning, one day*; Molina, disputation 7 of *De opere 6 dierum*; Salian in the *Annals* at the first day of the World; and Tirinus in the *Chronicon sacrum*, chapter 1. These hold that that earlier darkness lasted 12 equinoctial hours and preceded the first artificial day as a first night, and that the first natural day was formed of the two together; and so that the natural day began from night, although the artificial day began from the rising of the light. For this, they say, is why God said *and there was evening and morning, one day*, naming evening, that is, night, in the first place. [Margin: Arguments for the precedence of Night, and for the beginning of the natural day from night.] They confirm this from the text of Leviticus, chapter 23: *From evening to evening you shall celebrate your sabbaths.* This seems an argument that the Hebrews, from the very origin of the world, began their natural days from the beginning of night, as most cities of Italy do now, and as the Athenians once did, counting 24 hours from sunset to sunset — witness Pliny, book 2, chapter 77; Gellius, book 3, chapter 2; Macrobius, book 1 of the *Saturnalia*, chapter 3; and Censorinus, chapter 10.

And indeed this opinion is highly probable, and I chose it elsewhere; and I could confirm it. *First*, because God divided the primordial light from the darkness; but as soon as this is heard, the reader of Moses meets that darkness which was over the face of the abyss. Therefore, when God called the darkness

night, he included that darkness too under that name; so if that darkness was night properly and literally, that natural day began from night. *Second*, in Genesis 2 it is said: *In the day that the Lord God made heaven and earth*; and in Exodus 20: *Six days you shall labour and do all your works; but the seventh day is the Sabbath of the Lord your God; you shall do no work on it, you and your Son,* etc. *For in six days the Lord made heaven and earth and the sea and all that is in them, and rested on the seventh day; therefore the Lord blessed the Sabbath day and sanctified it* — which is repeated in Exodus 31. Since, then, heaven and earth were created in the first instant of the time of this world, and before the production of light, that whole time from the first creation of heaven to the production of light certainly belonged to the first of those six days; and it seems quite absurd that there was some time which did not belong to those six days, or which belonged to them, but as an extraordinary appendix, making up together with the artificial day and the following night one natural day longer than the others and unlike them. *Third*, it is certain from Leviticus, chapter 23, that by God's command the beginning of the Sabbath the Hebrews were to celebrate, and of their rest from all work, was regularly taken from evening; and it is equally certain from the passage of Exodus just adduced that the reason for this precept was that they should remember and imitate that first Sabbath on which God rested from all the work he had accomplished. Therefore, just as they ceased from all servile work right at the beginning of night, and began the Sabbath from then, as they still begin it now, so God too seems to have ceased from all work at the setting of the Sun, that is, at the beginning of night, and so to have counted the six natural days from then and completed them there, and not from rising to rising of the light.

Hence it is clear that what Martinengus says in the *Glossa magna*, page 545, is neither certain nor more probable: that the Hebrews, just as they had a double year according to Philo and Josephus, so had a double day — one natural and ancient, which they began from sunrise, the other legal, which they began from sunset — and that the genuine cause of this change was that they went out of Egypt in the evening. For granted that the beginning of the Sabbath was confirmed for this reason as well, and explained on that occasion, since it could perhaps have come into question, still the prior and weightier reason was that they should imitate the Lord, who rested from working at the beginning of night. Nor does it seem negligible that not only the Athenians, as we said above, but also the Egyptians once began the day from sunset, as Alex. ab Alexandro teaches, book 4 of the *Geniales dies*, chapter 20 — as though they had learned this from the Jews; and that Hesiod in the *Theogony* says Night arose from Chaos, as though prior to day, just as Chaos was prior to the distinction of things. *Fourth*, if anything stands against this view, it is above all the opinion of many Fathers and Doctors. But they seem capable of being reconciled with it, by granting them their principal intent: namely, that the first artificial day, and the rest after it, began from the East — that is, from the rising of the light, first in the East and propagated from there into the other regions — against those

who thought it was produced at noon or at setting; granted that the natural day began from the first instant of the creation of the World, which was to be under darkness for some hours. Nor is it an obstacle that this opinion was the Manichaeans'. For it is not established that they said anything erroneous in this; rather, on this as on a foundation laid, they said there were two principles: one of evils, which preceded and produced darkness and evil as something positive and a kind of substance; the other of goods. And so the holy Fathers, with St Augustine, contended that evil and darkness are not a substance or a being that could be produced by a positive action, much less by a different principle — granted that St Augustine, to overturn their foundation as well, denied them that the day began from evening. Finally, St Jerome, on chapter 2 of Jonah, says: *For in Genesis too the night is not of the preceding day but of the following: that is, the beginning of the future, not the end of the past.*

XXXVIII. [Margin: 2nd opinion, giving precedence to day.] The second opinion gives precedence to the day. And indeed, if we follow the bare authority of the Fathers, I find hardly any who, St Jerome excepted, called that earlier darkness night, or began that first day from it; but very many who say that that day was begun from the rising of the first light, that night followed it, and that from these, up to the following morning, the first natural day was formed. Let St Basil be heard, homily 2 on the *Hexaemeron*, where, after he has said [Margin: St Basil.]: *Evening is indeed the boundary common to both day and night; and morning, equally, is the neighbourhood of night to day. So, in order to grant the day the prerogative of primacy in the order of creation, he mentions the end of the day itself in the first place; then he adds what is the end of the night, since night follows the day.* At once he added: *For that earlier state of the world, namely before the rising of the primordial light, was not called night but darkness. For night is the name given to that portion of time which is distinct from day and opposed to it; and it is as the successor of day that it acquired this new name.* Indeed, St Basil seems to hold that in the words *evening and morning, one day*, only two parts of the artificial day are expressed, the morning and the evening, while night is understood, as a less principal complement of the natural day — just as when Psalm 89 says *the days of our years*, and Jacob says in Genesis 47 *the days of my life are few and evil*, the nights too are understood, as will be clear to anyone who reads that homily. [Margin: St Ambrose.] And in all this St Ambrose subscribes to St Basil, book 1 of the *Hexaemeron*, chapter 10. Having raised this question — *Some ask whether, since scripture mentioned evening first and morning afterwards, it may not seem to signify night before day* — he answered: *They do not notice, first, that it put day first, saying: and God called the light day and the darkness night. Next, that evening is the end of the day and morning the end of the night; so, in order to give day the prerogative and primacy of birth, it first signified the end of the day, after which night was to follow, and then afterwards joined to it the end of the night. Scripture could not put the night before the day, so that it included the times of both day and night under the name of day, and claimed for it, as the principal, the authority of the name.* He confirms this, as St Basil does, from the psalm mentioned and from Jacob.

According to these holy Doctors, then, the sense of those words, *And there was evening and morning, one day*, resolves into this: *And one day was made of the evening and the morning time*, the night being understood as having elapsed between the completion of the day and the beginning of the following artificial day. [Margin: St Chrysostom.] St John Chrysostom agrees, homily 3 on Genesis: *He pointedly named the end of the day and the end of the night as one, so as to establish a certain order and sequence of visible things*; and homily 4: *and one would rightly call evening the end of light, morning the end of night, and the completion the day; for this is what divine scripture means to make plain when it says: and there was,* etc. [Margin: St Nyssen.] St Gregory of Nyssa understood the names of evening and morning in the same way, in the book on the history of the six days: *He therefore named the withdrawal and setting of the light evening; and again, when the fire had run through the circle of the lower regions and restored its splendour to the upper parts, he called that daybreak, once it had come about, morning.* Remember that in his view the light was fire, segregated first of all from the other elements. [Margin: St Athanasius.] St Athanasius too, expressly, question 90: *From the primitive creation of the world,* etc., *day was prior; just as divine scripture also says that God said let there be light, and light was made, and that God called the light day, but the darkness he called night. Light was set first, for through it the first day came to be. And beginning first from light, we afterwards came to darkness.* [Margin: Procopius.] Procopius discusses this controversy, once a celebrated one, at greater length in the Commentary on chapter 1 of Genesis, and sets it out thus: *There is a great dispute whether day or night came first; but those who argue that day is older than night, as is commonly believed, proceed thus. God himself gave the primacy to day: for he first set the end of the day, namely evening, as though day had preceded night, and only when it had ended in evening was night born from its end. For night, as the rest from the day's work, is brought to us from the preceding day. But that face which the World had before the beginning of light is not properly called night, but rather gloom or darkness.* And since the Greeks call the natural day ν υκθήμερον [recte: νυχθήμερον] [Greek: nychthēmeron, "night-day"], as it were *Noctidium*, that is, consisting of night and day, Procopius there judges it should rather be called ήμερόνυκτον [Greek: hēmeronykton, "day-night"], as it were *Dienoctium*, because in this compound the day comes first. [Margin: St Damascene.] In addition, St Damascene, book 2 of *The Orthodox Faith*, chapter 7: *It was not night that was called first, but day. So day is first and night last: night therefore follows day, and from the beginning of one day up to the next day is one — so to speak — night-day; for scripture says: and there was evening and morning, one day.*

So much from the Greek Fathers — although, because of the affinity of interpretation, we have already attached St Ambrose to St Basil. Now, then, to the remaining Latins. [Margin: St Augustine.] Thus St Augustine, book 1 of *De Genesi contra Manichaeos*: *After this operation* — that is, of the light made — *evening came about as though the day were ended; but because night too belongs to its day, one day is not said to have passed unless the night too has passed, when morning*

came; and so thereafter the remaining days are reckoned from morning to morning. He repeats this in the unfinished book *De Genesi ad litteram*, chapter 7, and in book 1 of the finished work, chapter 10. [Margin: Eucherius.] Eucherius too, book 1 of the commentary on Genesis, chapter 2, uses almost the same words as St Ambrose above; [Margin: Iulianus.] and so does Iulianus, Archbishop of Toledo, book 3 *Against the Jews*: *In six days God made heaven and earth, and founded every creature formed by him on distinct days, beginning each day with light and ending it with evening, as scripture says: And there was evening and morning, one day.* [Margin: Iunilius.] Iunilius too supports them, in the *Hexaemeron*: *There was evening, as the light gradually set and, once the space of the day's length was complete, went under the lower parts of the World,* etc. *There was morning too, as the same light gradually returned above the lands and began another day; and up to this point one day was completed, namely of twenty-four hours. For it was fitting that the day, beginning from light, should be extended into the morning of the following day.* [Margin: Strabus.] Strabus has these very words in the ordinary Gloss. [Margin: Hugo Victor.] And Hugo Victorinus understood those words, *Evening and morning, one day*, in entirely the same way, adding that the primordial light arose in the East without a preceding Dawn, and that day naturally precedes night — so he writes in book 1 of *De Sacramentis*, part 1, chapter 9. [Margin: Richardus.] So too Richardus Victorinus, book 2 of the *Exceptiones*, chapter 7: *That primary light is believed to have been made in the place where the Sun now rises every day, and to have circled by the same path as the Sun, and so to have accomplished evening and morning; and this was the work of the first day.* [Margin: Hugo Carensis.] Add to these Hugo Carensis in the *Postills*: *For when the light,* he says, *made in the East, proceeded to the West in the manner of the Sun, evening came about; and as the same light migrated under the earth and came to the Rising, morning came about; and so one natural day of twenty-four hours was made.* So too, entirely, thought and spoke [Margin: Comestor.] Comestor, chapter 3 of the *Historia Scholastica* on Genesis; [Margin: Master.] the Master of the Sentences, on book 2, distinction 13; [Margin: Lyranus.] Lyranus in the *Postills*; [Margin: Albertus Magnus.] Albertus Magnus, part 1 of *De quatuor coaequaevis*, question 12, article 11; [Margin: St Thomas.] St Thomas, part 1, question 74, article 3, reply to 6; [Margin: St Bonaventure.] St Bonaventure, on book 2, distinction 13, article 1, question 2, in the second exposition; [Margin: Dionysius Carthusianus.] Dionysius Carthusianus, Commentary on Genesis, article 9; [Margin: Caietanus.] Caietanus on chapter 1 of Genesis; [Margin: Vielmius.] Vielmius, at the same place, lecture 3; [Margin: Lippomanus.] Lippomanus in the *Catena*; [Margin: Pererius.] Pererius, book 1 on Genesis, page 54; [Margin: Martinengus.] Martinengus in the *Glossa Magna*, from page 540; [Margin: Suarez.] and Suarez, book 2 of *De opere sex dierum*, chapter 3, number 12. Their words are ready to hand, and I have judged they should not be quoted, to avoid prolixity. Nor does Tostatus reject this opinion, in his commentary on Genesis; he reports it as probable.

XXXIX. [Margin: 3rd opinion, intermediate between those already mentioned.] The third opinion begins that first natural day from Evening, taking Evening to begin from Noon. Placing the Sun, or the primordial light, on the Meridian, it holds that that first day had its morning not before it but after it, and that this is why Moses said, *there was evening and morning, one day*; so that the first artificial day had only six hours, from noon to setting, while the six preceding hours, in which the World was in darkness, belonged not to the first artificial day but to the completion of the natural day. This opinion is therefore intermediate between the two extremes already mentioned. With the former it begins the day from Evening — which leans and declines rather towards setting — and begins the natural day from the preceding darkness; but with the latter it begins the artificial day from Noon, which belongs to the day rather than to the night. [Margin: St Bonaventure.] [Margin: Steuchus.] [Margin: Aegidius.] [Margin: Cornelius.] [Margin: Ficinus.] This is the view of Augustinus Steuchus, or Eugubinus, in the *Cosmopoeia* on chapter 1 of Genesis; of Aegidius, part 2 of the *Hexaemeron*, chapters 2 and 6; and of Cornelius à Lapide on chapter 1 of Genesis; and St Bonaventure reports the same opinion and does not think it improbable, on book 2, distinction 13, article 1, question 2. Speaking of the fourth day, Marsilius Ficinus [Marsilio Ficino] supports them, in the book *De Sole et lumine*, chapter 10, where he teaches that the Sun was produced on the Meridian, and that with respect to our hemisphere the day began from noon. From this view, however, it follows that the remaining days, both artificial and natural, began from the rising of the light or of the Sun above the horizon. For to fill out the first natural day it counts the 6 hours in which the world was in darkness; and by the following morning it does not understand the time from the rising of the light to noon — which, it teaches, belongs to the following day — but the moment at which the first night was completed and the light, or the Sun, arrived from noon, by way of setting and midnight, at its rising. Besides that reason — that Evening was named first by Moses — these Authors add this one too: that the works of God are perfect, and that the Sun or the light on the Meridian illuminates the hemisphere more perfectly and evenly in every direction; and that most Astronomers usually begin the day from Noon, as from a more certain point of the day. [Margin: This opinion is rejected.] But if we wish to speak with most of the Fathers and Doctors, according to what was said at numbers 37 and 38, the light or the Sun began the first artificial day from the East; and it is more probable that that [?] first day, both artificial and natural, was the norm for the rest, or at least was not unlike the two that followed it, and so had 12 hours of light and as many of night — not only six of light and eighteen of darkness, as this opinion supposes. And the greater perfection of an equinoctial day is that it be whole and fill a time of 12 hours, rather than that the Sun should shine more ardently from the summit of the sky at its beginning than in its progress, and at once begin to decrease — in keeping with the text, *The path of the just is like a shining light, growing up to the perfect day*, Proverbs 4. Moreover, the way of beginning the day from noon is

too subtle to serve the common people and ordinary use, because finding the meridian line calls for no common skill; for the common people are used to observing the rising and setting of the Sun, as the more certain sign.

XL. [Margin: 4th opinion, beginning the day from night in another way.] The fourth opinion, already indicated at the beginning of number 35, was that of Catherinus and of Lusitanus, that is, Hieronymus ab Oleastro, on Genesis. [Margin: Catherinus. Oleaster.] They think that Evening was put first, or named first, by Moses before the morning time because the Sun or the primordial light was placed first on the western horizon with respect to Palestine, and began from there to rise for the hemisphere opposite that region; and, when a night of 12 hours was completed, reached the east of Palestine and made the first morning; and then, after another 12 hours, returned to its setting, and so completed one natural day. So this opinion agrees with the first in beginning the natural day from the beginning of night, but differs from it in not counting, in the first natural day, the time of the darkness that preceded the primordial light. Catherinus confirms his opinion both from the fact that the Hebrews celebrated their sabbaths from evening to evening, from Exodus 20, and from the fact that the Egyptians used to begin the day from sunset, as perhaps did many of the ancients — which is why Thales of Miletus, when asked, answered that night was prior to day.

But what more improbable thing could be said than that the light, as soon as it was produced, was hidden, or withdrawn, from that hemisphere which was to be the principal dwelling of men, for which Moses chiefly wrote, and which was to receive first the light of divine knowledge and of the Mosaic and Gospel law, and was shown first to that hemisphere which was to come much later to civil culture and to the knowledge of the true religion? Next, since heaven and earth are said to have been created on the first day under darkness, either that darkness which, after that first instant, was over the face of the abyss was over the hemisphere of Palestine only, or it was there too, but its time was a supernumerary appendix to the first day, and that day was longer than the rest and unlike them; and neither of these fits the letter of Moses well. If, on the other hand, that time belonged in no way to the first day, it follows that heaven and earth were created not on the first day but before the whole first day. Since, then, of the four opinions already mentioned, the third and the fourth have far fewer patrons and are much more improbable than the first and the second, it remains for us to choose one of those two earlier ones.

XLI. [Margin: Five acceptations of Evening.] Before I put forward my own view, however, I note that Evening can be taken in five ways, and Morning, its opposite, in as many. *First*, so that evening signifies the indivisible moment at which the Sun sets, and morning the moment at which it rises. *Second*, so that evening signifies the twilight that follows sunset, or the earlier part of that twilight, in which the star of Venus appears when it follows the Sun. At that time this star is called Vesperugo by Plautus, Vesper by Ennius, and Hesperus and Vesper by Virgil, as Censorinus notes in *De die natali*, chapter 10, and St

Isidore in book 5 of the *Etymologies*, chapter 31; for they allude to those lines of Virgil:

Ante diem clauso componet vesper olympo ("Before that, Vesper will close Olympus and lay the day to rest"), and

Ite domum satur e, venit Hesperus, ite capellae ("Go home, well-fed [?]; Hesperus comes; go, she-goats").

Morning in this sense will signify either the morning twilight or the part of it nearer sunrise, that is, Dawn; and Lusitanus and Vielmius, lecture 11 on Genesis, take it in this way. They confirm it both from the Hebrew word *Ereb*, which signifies Evening, from the verb *Harab*, which means to bind or tie together, since it is a kind of bond between day and night; and from Plautus, who called this twilight the first evening — Livy calls it the first darkness, Macrobius the first torch. From this they explain the text of Exodus 12, where the Jews are commanded to slaughter the lamb between the two evenings, that is, about the middle of this twilight, which divides it in two: an earlier part nearer the sunset just completed, and a later part more like night. Morning, in turn, is called in Hebrew *Boquer*, from the verb *Bacar*, which means *to discern*, because in the morning twilight visible things begin to be discerned. *Third*, Evening can be taken for the whole time in which the Sun, descending from the meridian, slips down to its Setting, and Morning for the time in which the Sun climbs from its Rising to Noon. In this sense we are said to lunch in the morning and dine in the evening, even in high summer; or else so that Morning is the time from midnight to sunrise. *Fourth*, Evening can be taken for the time in which the Sun descends from Noon to midnight, and Morning for the time in which it climbs from midnight to noon. *Fifth*, finally, so that Evening signifies the whole night — but the night following the day that has elapsed — and morning the whole artificial day. In this way the text of Exodus 12, *between the two evenings*, could be understood of the moment of sunset. The text of Genesis, *Evening and Morning, one day*, could also be understood in as many ways: whether those words are taken for the two boundaries, indivisible or divisible, between which day and night are enclosed, as in the 1st and 2nd acceptations; or for opposed parts, making up the day and the night adequately or inadequately.

XLII. [Margin: Our opinion.] With this premised: since the arguments brought at number 37 for the first opinion are strong, and the authorities adduced for the second at number 38 are more numerous and more ancient, the two opinions seem to me to call for reconciling, as follows. The first natural day — properly so called, indeed, but taken broadly, for a day formed of night taken broadly and of time taken broadly, that is, without actual motion — began from the darkness lasting 12 hours, or a duration commensurable with them and equivalent, which preceded the light first produced in or about the East of Palestine; whereas the first artificial day took its beginning from that first production of light, and when its evening, taken in the first, second or third way, was complete, the first day, natural as well as artificial, was complete

— although only the artificial day is expressed by *Evening and morning*. And it was in this way that the Hebrews understood that day, both in sanctifying the sabbath and before. From this it follows that the second, third, fourth and remaining days, and so the sixth, which are counted in sacred Genesis and within which God completed his work, were completed at Evening, that is, at the setting of the Sun or of the light that was the Sun's deputy; and that God began to rest from work in the night preceding the sabbath day taken artificially. In saying this, however, I do not on that account say that evening was named by Moses before morning; for that darkness can be called evening neither strictly nor broadly. Nor did he mean to express night by the words *evening and morning*, but only parts of the artificial day, composed of evening and morning time, so as to signify to us that those days were not unlike ours but had the same alternations — granted that he named first that part of the day which contained the consummation, maturity and perfection of the day, and of the works accomplished on that day, as its fruit, before the part which contained only its beginning and, as it were, the flower of the day. Taking the Natural Day more strictly, however, for the aggregate of the artificial day and of night taken strictly — that is, night as the privation of light once produced — and of time taken strictly, as the measure of the motion of the Sun or of the light that was the Sun's deputy, I say that it began from the rising of the light, from which the artificial day began, and that the artificial Day preceded night taken strictly, as the second opinion holds. So, on this view, the same moment of the light's rising was the beginning of both the natural and the artificial day, but the end of the two was not the same; whereas, according to the first opinion, the same moment was the end of both days, but their beginnings were different moments. I have not enumerated, however, a conceivable fifth opinion: namely, that the first natural day was composed of six earlier hours of darkness, of the 12 following hours of light, and of the remaining six hours from setting to the middle of the night, because I have found no author who has asserted it, even though the Romans and some Astronomers have reckoned days from midnight to midnight.

XLIII. [Margin: Light produced and the Angels beatified at the same time.] Supposing, finally, a time under darkness from the first instant of the creation of the world down to the first production of light, whether of 12 hours or thereabouts, it could be asked whether it is probable that that time of darkness was the one in which the battle took place between the good and the bad Angels, and that the first instant of light was the one in which the holy Angels were confirmed in grace and raised to the light of glory — so that that corporeal light is to be understood literally, but was, symbolically and mystically, a sign of the spiritual light produced in the minds of the Angels. Abbot Rupert [Rupert of Deutz] certainly held this and stated it in express words, in book 1 of his commentary on Genesis, chapter 10, and so did Aegidius on the Hexaemeron, part 2, chapter 2. But these matters are nothing to us now.

CAPVT II.

Chapter II.

De Opere Secundi Diei. Seu quid fuerit ac ſit Firmamentum illo die factum, & ex qua materia; Quidue & quales Aquæ ſuper cælos.

On the Work of the Second Day; or, what the Firmament made on that day was and is, and from what matter; and what the Waters above the heavens are, and of what kind.

I. We set out three questions in one, because they are so entangled with one another that none of them can be solved without the other two. We must inquire whether the starry and visible heaven was made out of elemental water by condensation and solidification; next, whether every starry heaven, or the whole of it, was so made, or at least the eighth sphere, the highest of the visible ones; lastly, whether the waters above the heavens are liquid and distinct from the solid heaven, or enclosed within it and liquid in potency, not in act. For once these points are settled from sacred Scripture and from the Fathers and Doctors of the Church, we shall dispatch many other questions more easily and more briefly, and shall be able to pass judgement on the opinions of others with greater and more solid calm. Otherwise, it is incredible how great a confusion of opinions and questions is found among writers on this passage of sacred Genesis. Amid this multiplicity we shall choose the view that so accords with the letter of sacred Scripture that it reconciles as many of the Fathers and Doctors as possible with one another, conflicts least with astronomical observations, and, finally, presents the workmanship of God more reasonably. This we shall try to accomplish in the following Questions and Conclusions.

Quæſtio 1. An ex Aqua denſata & ſolidata in modum glaciei aut cryſtalli, aliquod Cælum ſecunda Mundi Die factum ſit?

Question 1. Whether some Heaven was made on the second Day of the World out of Water condensed and solidified in the manner of ice or crystal.

II. [Margin: 1st Conclusion, and its proof from the name Firmament and from sacred Scripture.] The Conclusion is affirmative. It is proved, first, from the name that sacred Scripture gave this Heaven, namely Firmament — in Hebrew *Rachiagh*, or *Rakiaa*, or *Raquagh*, for different people pronounce it differently — from the verb *Rcah*, or *Rakaa*, or *Raquagh*, which means both to spread out or extend and, by extending, to make firm and consolidate, as Lippomanus notes. Further, Pererius and Martinengus, with Caietanus on this passage, teach that a thing is extended in four ways: [Margin: 5 modes of extension.] namely, 1. by the unfolding of a thing folded up, as when sails and curtains are spread out, or when a sponge first squeezed by the hand strives to restore itself to its former occupation of space; 2. by beating, as when metal is

beaten out into plates with a hammer; 3. by rarefaction, as when water swells into bubbles with heat or with blowing, or boils over out of a vessel; 4. by increase of substance, as when plants and infants grow into trees and men. But St Jerome and Vielmius have a fifth mode, namely fusion, by which metal, or anything that can be melted, is cast in such a way that it keeps the solidity and stability of the shape once received.

Now those who favour the fluidity of the heaven, or who understand by the name Firmament the air, or a mere stability of the aether in bounding the waters on either side, without hardness or solidity strictly taken, contend that the name *Rachiagh* ought to have been translated according to the first mode of extension, and that the text should say *Let there be*, or *Let it be*, an *Expansion* or a *Spreading-out*. So Calvin, on Tanner's testimony, Caietanus, Steuchus, Vielmius and Pererius; and they adduce the text of Psalm 103, *Stretching out the heaven like a skin*, or like a curtain and a tent; and Isaiah 40, *Who stretches out the heavens as nothing, and spreads them out as a tent to dwell in*. But these examples do not altogether favour them, because they suppose at least that the thing unfolded has some solidity.

[Margin: The name Firmament is defended.] Next, St Jerome and the Vulgate version have translated *Firmament*, and the Septuagint translators στερέωμα [Greek: stereōma, "firmament"], which signifies a solid body; Velleius in Cicero, *De natura deorum* book 1, said that solid and firm bodies were called στερέμνια [Greek: steremnia, "solid things"] by Epicurus on account of their firmness; and even now the Hebrews who write on Geometry, where solid and compact bodies are treated, call them στερεώματα [Greek: stereōmata, "solids"], and the treatment of them στερεωμετρίαν [Greek: stereōmetrian, "stereometry"]. Since this is so, we too ought to take this name in the same sense, so that it does indeed signify extension or expansion, but either according to the second mode, for beating or, as it were, hammering — as Pagninus takes it, and Oleaster, or Lusitanus, who explains in this way this passage of Genesis, and that of Isaiah 42, *Who spreads out the earth and its offshoots*, where *Rocah* stands, that is, *spreading out*, or *who spreads out*; and Jeremiah 10, *Silver spread out with hammers is brought from Tarshish*, where for *spread out* the Hebrew edition has *murecah*; and that passage of Ezekiel 6, *Strike with your hand, or stamp with your foot*, where in Hebrew, for *strike* or *stamp*, stands *Vrechah*, that is, spread out thus, as one who spreads out metal or clay by pounding it with hand or foot. Or else, certainly, the name Firmament is to be taken in the 5th sense, so as to signify an expansion by force of which a solid and stable shape is nevertheless left in, or given to, some thing: as when metals are cast into statues, or — what pleases me more, and sets before the eyes, as it were, both forces of this name and God's manner of proceeding in this work — when glass, first melted in the furnace, is blown by the mouths of glassworkers making very large flasks out of a little glass; for they spread that material out in such a way that they nonetheless make something solid and firm out of it.

And indeed several other passages of sacred Scripture favour this fifth mode: namely Psalm 32, *By the word of the Lord the heavens were made firm*, where the Septuagint has ἐστερεώθησαν [Greek: estereōthēsan, "were made solid"], that is, *were solidified*; and 2 Paralipomenon 6, where Heaven is called *a most firm dwelling*; and Proverbs 3, *The Lord by wisdom founded the earth; he established the heavens by prudence*; and Job 14, *Until the heaven be worn away* — for what is worn away supposes solidity; and Hebrews 4, *Who has penetrated the heavens* — for that, as St Thomas teaches, part 3, question 57, article 4, reply to 3, is said more properly of solid bodies than of fluid ones, since if they were all fluid there would be no need of a penetration strictly taken; and that text of Isaiah 51, *The heavens shall melt like smoke, and the earth shall be worn away like a garment* — for what will become liquid was surely solid before. As for what some translate with the Septuagint, *The heaven was made firm like smoke*, it agrees neither with the Hebrew nor with the Vulgate edition, nor with St Jerome, nor with Pagninus, nor with Arias Montano, nor with the comparison drawn from smoke — granted that St Basil, homily 1 on the Hexaemeron, accepts the Septuagint version.

But the most celebrated passage of all is the one in Job 37, where Elihu says: *Perhaps you fashioned the heavens, which are most solid, as if cast of bronze.* For although that saying is not a matter of Faith, since it is not the sacred historian's own nor uttered from the mouth of God, nevertheless, so long as Elihu's sayings contain no falsehood or contradiction and are not found rebuked by God, they have great authority, like certain moral sayings, as the sayings of a very expert man speaking from the ancient tradition about the structure of the heavens set out by Moses. For the sayings of the two remaining friends, his and Job's, are also adduced by Sts Peter and Paul as having great and irrefragable authority. Thus in 1 Corinthians 3 the saying of Eliphaz the Temanite is brought from Job 5, *Who catches the wise in their craftiness*; and in 2 Peter 2, from the same Eliphaz, *Behold, those who serve him are not steadfast, and in his Angels he found wickedness.* So too the holy Fathers u- se that saying of Bildad the Shuhite from Job 23, *The stars are not clean in his sight*; and those words of Elihu from Job 34, *Who does not accept the persons of princes*, and in the same place, *Who makes the hypocrite reign because of the sins of the people*.

Finally, very many Fathers and Doctors understood this name in this sense. They are to be brought forward presently for the 2nd proof, in selected words of their own, so that readers may not think that we drag them to this sense forcibly, or from too remote a conjecture or too general a phrase — especially since this question is of the greatest moment and, because these authorities have been passed over, has not been discussed by many as thoroughly as was fitting, Martinengus, Salian and Tanner excepted, whom I have found the most diligent of all in this matter.

III. Secondly, then, the conclusion is proved by the Authority of the Fathers and Doctors of the Church. Before them let me be allowed to bring forward Josephus, [Margin: Josephus.] who in book 1 of the *Antiquities*, chapter 1,

has this: *After this, on the second day, he placed the heaven above all things and, distinguishing it from the others, commanded it to be set in itself; and, fixing crystal round it, he tempered it with moisture for watering the earth.* From the mouth of St Peter, again, St Clement, Pope, [Margin: St Clement.] in book 1 of the *Recognitions*: *The water that was within the World, in the middle of the space of that first heaven and of the earth, is stretched out as if congealed by frost and solidified as crystal; and by a Firmament of this kind the middle spaces of heaven and earth are, as it were, shut off; and the creator called that Firmament heaven, naming it with the word of that older one. And so, though the fabric of the whole world was one house, he divided it into two regions.* [Margin: Tertullian.] Whether the book *On the Trinity* ascribed to Tertullian is Novatian's, as Pamelius [Jacques de Pamèle] contends, or Tertullian's own, in it those words of Ezekiel 1, *The firmament as the appearance of terrible crystal*, are explained thus: *All things being covered over from above by the crystal, that is, by the heaven covering all things; so that what had been solidified into the firmament at God's command out of the flowing matter of the waters, like strong ice, dividing in half the waters that had long covered the earth, might sustain on a kind of back the weights of the upper water, its strength reinforced by the frost.*

How much water was spent on this work is declared by St Hippolytus of Rome [Margin: St Hippolytus.] — perhaps that Bishop of Portus and Martyr — in Martinengus, page 571: *A third part of the waters he fixed by his power in the middle; a third he raised above the firmament; and a third, finally, he willed to be below, namely for the use of men.* [Margin: St Hilary.] Although St Hilary, in his exposition of Psalm 135, does not explain this solidity, he nevertheless says: *For with the waters raised up he tempered that very nature of the first heaven, which, kindled by the power of God on high, could by no means have been endured by the lower natures. The lower heaven, however, he stretched out not uniform but manifold; and, calling the whole of it the Firmament, he solidified it with a firmness strong enough to sustain the upper waters and to temper our air.* So, between the kindled heaven, or Empyrean, and our air, he recognizes heavens that are all solid, and waters above them. [Margin: St Caesarius.] But St Caesarius, brother of St Gregory Nazianzen, in the dialogues, questions 4, 5 and 6, teaches that the firmament set between the upper and the lower waters is different from the heaven that Moses mentioned in the first place, and is of a crystalline nature, congealed by divine power so that it can carry and separate the upper waters.

[Margin: Acacius.] Let us now hear Acacius, who flourished in the same century; for he, as is found in the Catena of Lippomanus and the Gloss of Martinengus, says: *The first heaven was named heaven, not firmament; but the second received the name both of heaven and of firmament — of heaven because it is above us and renders us the office and use of the earlier heaven; of Firmament because it consisted of the fluid essence of the waters, and that fluid and liquid nature was made most dense and most solid by God, the maker of all things. Divine scripture, therefore, recognized only two heavens.* And a little later he seems to put its solidity on a par with the solidity of the earth, when he says: *But this too is to be known,*

that the earth also is called a firmament in scripture, as when it says, Psalm 135, Who made the earth firm above the waters, and Isaiah 51, The Lord who made the heaven and fixed it, and made the earth firm. [Margin: Severianus.] But plainer words are used by a writer of the same century, namely the fourth, Severianus, as is found in the same Catena and Gloss: *This water rose above the earth by thirty cubits (for example). God said, Let there be a Firmament in the midst of the waters, and without delay it was compacted. A kind of crystalline congealing in the midst of the waters is this very heaven, which, suspending half of the waters with itself, left the rest below.* And again: *So God made this heaven — not that highest one, but the one that is visible — out of the waters, and fixed it like crystal. See the power of the works, that you may admire the craftsman: he willed half of the waters to be above and half below.*

[Margin: St Chrysostom.] Next, St John Chrysostom, homily 4 on Genesis, though he does not dare to define how the Firmament was made, holds this for certain: that it was made fit to carry the upper waters on its back — which can hardly be conceived as done without solidity. For he says: *What is "Let there be a Firmament"? As if one were to say in human language: let there be a kind of wall and partition, dividing in the middle and making a separation.* And a little lower: *He ordered some waters to be borne below the Firmament, and others to be above the back of the Firmament. But what, after all, shall we say this Firmament is? Condensed water, or air spread out, or some other essence? No prudent person would rashly assert this. For what is said must be received by us with great modesty and gratitude, and we must not go beyond our nature and search into the things that are above us; but only know and hold this among ourselves: that by the Lord's command the Firmament was produced, making a separation of the waters, able to contain some beneath itself and to carry others on its back.* Further on, however, we shall see that he is not speaking of the heaven where the Planets move, since he thinks it immobile; or that he does not recognize in it solidity with the hardness that Claudius Marius Victor nevertheless supposed, [Margin: Claudius Marius.] book 1 of the commentary on Genesis, in these verses:

..... Cum se firmissima moles Fluctibus e medijs concreto corpore cedens Extulit, ac late duro solidata rigore, Divisas suspendit aquas, gelidumque profundum Axibus obiecit calidis, seque aequore septo Nixa superfudit rebus, quas circite vasto Contegit aethereum, deducto hinc nomine, caelum.

("…When the most firm mass, yielding from the midst of the waves with congealed body, raised itself up, and, solidified far and wide with hard rigidity, held the divided waters suspended, and set the icy deep against the hot axes; and, resting on the enclosed sea, spread itself over the things that the aethereal heaven — its name drawn from this — covers with its vast circuit.")

[Margin: St Jerome.] With Tertullian, too, expounding Ezekiel as I showed above, St Jerome agrees in the Letter to Oceanus: *Between heaven and earth the Firmament is built, which, according to the etymology of the Hebrew tongue, takes the name heaven, that is, Samaim, from the waters; and the waters that are above the heavens are set apart for the praises of God. Hence also in Ezekiel the*

Prophet crystal is seen stretched out above the cherubim, that is, compacted and denser waters. [Margin: St Augustine.] St Augustine, book 2 of *De Genesi ad litteram*, chapter 1, points to the opinion of these authors before him and does not refute it, saying: *The Firmament, as it seems to some, is ice of waters; and it is called Firmament because it was made firm by waters congealed by divine power, which is called heaven from hiding, or concealing.* Yet further on he holds this much at least for certain: *This Firmament was made from the substance of water mentioned above*; and a little after: *The Firmament, then, that is, heaven, was made in the midst of the waters, to divide between the water that was above the firmament and the water that was below the firmament, so that by the power of God the firmament stood in the midst of the waters, having water beneath itself, within itself and around itself.* See him also at question 106 in the *Questions on both Testaments*, which are found in volume 4 of the works of St Augustine.

[Margin: Gennadius.] Let Gennadius, an author of the fifth century, be counted with these. On Genesis, as the Catena of Lippomanus and the Gloss of Martinengus have it, he says: *So he named it Firmament from the very workmanship of the thing, because, whereas it was before of a pliant, fluid and soluble nature, it received a solid and in no way mobile compaction.* [Margin: Theodoret.] Theodoret, almost his contemporary, set out his mind thus in question 11 on Genesis: *For it was necessary to know, from the reckoning of the time and from the very manner of creation, the diversity of the heavens: that one was created before the light and the other after the light; and that the former was created not out of any matter, the latter out of water. For, he says, Let there be a Firmament in the midst of the water, to separate the waters from the waters through the middle. For thus the heavens obtained their name from the thing itself.* He alludes to the Hebrew name *Samaim*, that is, *there waters*, and goes on: *Since it was composed of the fluid substance of waters, and, being fluid by nature, was condensed and consolidated, it was named Firmament.* [Margin: Eucherius.] More briefly Eucherius, book 1 on Genesis: *By the name Firmament he signified heaven, because it is strongly and firmly composed.* [Margin: Iunilius.] Let Iunilius close this fifth century; in his Commentaries on the Hexaemeron he discourses thus: *Here is described the creation of our heaven, in which the stars are fixed: which, it is agreed, is the firmament in the midst of the waters. For that there are waters placed beneath it we also see for ourselves in the air and on the lands; that there are waters placed above it we are taught not only by the authority of this scripture but also by the words of the Prophet, who says: Stretching out the heaven like a skin, who cover its upper parts with waters. The starry heaven, then, is agreed to be the Firmament in the midst of the waters. Nor does anything prevent its being believed to have been made of waters too. For we know what the firmness of crystalline stone is, and what its transparency and purity — and it is certain that it is produced from a gathering of waters. What prevents us from believing that the same disposer of natures solidified the substance of the waters into the firmament of heaven?* I have already said that there are some who take Iunilius and Bede for the same man, although Bede belongs to the 8th century. First, then, from the 6th century we shall bring forward Procopius and Olympiodorus.

[Margin: Procopius.] Thus Procopius of Gaza, in his commentaries on Genesis, on the Firmament made not in vain on the second day, says: *Nor would anyone say that its creation was superfluous. For while it received on its back, as it were, no small mass of waters, it came about that the waters left behind flowed together more readily and more quickly into one collection, and that the earth, the flood removed, emerged the more quickly, fit for habitation.* But this is remarkable: he teaches that this is the common opinion of Theologians — namely, that this heaven was made of congealed water — since he says: *There are those who maintain that its nature is little known and little ascertained by us; although, by the well-trodden way of all Theologians, it is handed down that it was compacted of water, and that it is called by the Hebrews Samaim, a word which denotes crystal or frozen water.* [Margin: Olympiodorus.] After him Olympiodorus, in his Catena on Genesis: *So, he says, I myself made the most tenuous nature of heaven solid, as if one had fitted a cube together with stone* — so, that is, that solidity signifies not only threefold dimension, as in a cube, but also hardness, as in a cube of stone.

[Margin: Strabus.] Let us pass now to the ninth century, in which Strabus, in the ordinary Gloss, expounding the work of the second day, has the scent of Iunilius's opinion: for after copying out his view almost word for word, and using the comparison with crystal, he then added of his own: *If anyone is troubled how waters, fluid by their nature and apt to slip downwards, can stand above the heaven, whose shape seems to be round, let him remember the one of whom it is written by Job:* [Margin: Job 20 [recte: Job 26].] *Who binds up the waters in his clouds. For he who below the heaven binds up waters, held back for a time in the vapours of the clouds, can suspend waters above the sphere of the heaven, so that they do not slip, not by vaporous thinness but by icy solidity — he who also hangs the mass of the earth upon nothing. But what kind they are, and of what use, he knows who founded them.*

[Margin: St Anselm.] St Anselm of Canterbury lived at the same time, and accordingly wrote things not unlike these, in *De imagine mundi*, book 1, chapter 25: *The upper heaven is called the Firmament, because it is a firmament in the midst of the waters: that is, spherical in form, watery in the nature of waters, adorned with stars on every side, solidified out of waters like ice, indeed like crystal; hence it is also called the Firmament.* With these words he certainly seems to describe the eighth sphere, or heaven of the Fixed stars; for this is the upper one, and adorned with stars on every side. The tenth century has been called the iron century, because it had scarcely one or two writers of any name. But at the end of the eleventh century Anselm of Laon said in the interlinear gloss: [Margin: Interlinear Gloss.] *The upper part of the waters was congealed in the manner of crystalline stone; the lower was reduced into matter.* [Margin: Hugo Victorinus.] Not long after him, Hugo Victorinus, *De Sacramentis* book 1, part 1, chapter 17: *The firmament was drawn out and made into such a form that, coming in between as a kind of middle with its circuit, it separated and divided from one another that great and immense heap of waters, and made of the waters waters and waters: that is,*

waters which it would embrace within its circuit and contain beneath itself, and waters which it would leave outside and above the round of its boundary.

[Margin: Comestor.] More plainly the Master of the Scholastic History, on Genesis chapter 4, namely Petrus Comestor: *So on that day God made the firmament in the midst of the waters, that is, a certain outer surface of the world out of frozen waters, consolidated like crystal and translucent, containing the rest within itself, after the likeness of the shell that is on an egg; and in it the stars are fixed. And it is called firmament, not however because of its own solidity, but because it is the boundary of the waters that are above it, firm and impassable. It is also called heaven [cælum] because it conceals [cælat], that is, covers, all sensible things.* Who does not see that in this passage only that outermost heaven is designated in which the fixed stars are, and which is the outermost shell and surface of the visible world? [Margin: Master.] Petrus Lombardus, on book 2, distinction 14: *Here is described the creation of that heaven in which the stars are fixed; beneath which are placed the waters in the air and on the earth, and others placed above, of which it is said, who cover its upper parts with waters. In the middle, then, is the firmament, that is, the starry heaven, which can be believed to have been made of waters. For crystalline stone, whose firmness and transparency are great, was made of waters.*

[Margin: Richardu[s?].] In very few words Richardus, book 2 of the *Excerptions*, chapter 7, indicated that the stars are fixed in the heaven like nails and revolve with it, and hence that the heaven is solid: *The Firmament is proved to be revolving from the stars fixed in it above.* [Margin: Hugo Car[?].] Hugo Carensis, in the *Postills*, held to the Master of the Scholastic History, as is clear from these words: *The Firmament, the surface of the sensible world, made of waters congealed into crystal, as they say, containing all other sensible things after the likeness of the shell of an egg; and it is called firmament because it is firm.* [Margin: Dionysius Carthus.] Dionysius Carthusianus does not depart much from this, commentary on Genesis, article 10, where he teaches that the Firmament was made on the second day not as to its substantial form but as to certain qualities, especially solidity; and he adds: *The Firmament, that is, the heaven of the stars, which is the eighth sphere, because beneath it are the seven spheres, or orbs of the heaven, of the planets.*

But although not all of the 27 authors adduced express a solidity of the starry Heaven — at least one that includes a hardness like that of ice or stone — but only that it was made of water, most of them nevertheless express it, or indicate an equivalent. Its Solidity, moreover, was taught expressly and absolutely by the more recent Theologians, [Margin: Martinengus. Molina. Delrius. Cornelius. Serarius. Salianus. Tannerus. Sà.] especially Martinengus in the *Glossa magna*, page 590, and, from our Society, Molina, *De opere sex dierum*, disputation 2, last chapter; Martinus Del Rio [Martín Antonio Delrío] and Cornelius à Lapide on Genesis, at the 2nd day; Serarius on the 2nd Epistle of St Peter; Salian in the *Annals of the Old Testament*, at the 2nd day; Tanner, volume 1 of the *Theology*, disputation 6, question 3, doubts 1 and 2; and Sà [Manuel de Sá] on that text of Apocalypse 4, *And in the sight of the throne, as it were a sea of glass like crystal*.

Quæſtio 2. An aliquod Cælum Sidereum ſecunda die factum aut relictum fuerit fluidum, vel ita ſolidum, vt duritiem tamen non habuerit nec habeat, ſed alia de cauſa firmum ac ſolidum dictum ſit ex Scripturis & Patribus: Vbi & de motu Planetarum in cælo.

Question 2. Whether some starry Heaven, made or left on the second day, was fluid, or so solid that it nonetheless neither had nor has hardness, but was called firm and solid for another reason — from the Scriptures and the Fathers. Where also on the motion of the Planets in the heaven.

IV. I suppose here, from Genesis 1 and from the Fathers to be cited in section 3, chapter 1, number 9, that the Firmament is that whole space in which the wandering and the non-wandering stars were placed by God, or in which they were produced.

[Margin: 2nd Conclusion.] Let this CONCLUSION likewise be affirmative. Although it cannot be shown positively from the sacred Scriptures, it will become manifest from not a few Fathers and Doctors — indeed from the scriptures as well, but negatively, in number 5. For some think it is called the Firmament because it is something corporeal, or a body having threefold dimension, and think this suffices for solidity; some because it is an impassable boundary of the waters; some because it is incorruptible; some, again, expressly affirm that it is penetrable by rains or by stars, and of itself immobile; some, finally, ascribe solidity not to the whole starry heaven but only to its highest part, or the eighth sphere — as will presently be made plain. [Margin: Philo.] Philo, book 1 *De mundi opificio*: *He aptly called the heaven firmament, as a corporeal thing. For a body is naturally firm and solid, having three dimensions. And what other notion can there be of a solid and of a body than dimension in every direction?* [Margin: Origen.] The same was the notion in Origen, homily 1 on Genesis: *After that he makes the Firmament, that is, the corporeal Heaven. For every body is without doubt firm and solid; and this is what divides between the water that is above the heaven and the water that is below the heaven.* [Margin: St Basil.] In almost the same sense St Basil, homily 3 on the Hexaemeron, understood the Firmament — namely as a body having threefold dimension, but fit to resist, yet without hardness. For when he had said that on the second day a Heaven different from the first and of a more Solid nature was made, he explains himself more fully in this way: *Outsiders call that body firm which is, as it were, solid, dense and full, to distinguish it from the Mathematical body, which consists in dimensions alone — in breadth, I mean, length and depth. But firm and solid is that which, with the di- mensions, can push back and resist. Sacred Scripture, however, is accustomed to call firmament whatever is very strong and does not yield, so much so that it often uses this very word even of condensed air, as when it says: Who makes the thunder firm. For Scripture has called the firmness of the thunder that solidity and resistance of the wind shut up in the hollow bosom of a cloud which, bursting out violently,*

produces the sound we call thunder. In this place too, therefore, we judge that this word was established by Scripture for a firm and solid nature, fit to hold back and restrain the waters, which by their own nature slip away. Then, rejecting the hardness of ice or crystal, he adds: *Yet the firmament, although according to the common and widespread opinion it seems to have arisen from water, is not to be thought similar either to water congealed into ice, or to any such matter made from water as the nature of crystalline stone is agreed to be, or as is the nature of the specular stone, which grows among the metals, etc. For it is surely the mark of a childish and simple mind to hold such opinions about the celestial bodies.* And again, expounding the name Firmament: *Plainly, he intimates a nature in no way resisting; he does not say that the firmament is of the kind that is solid, heavy with its own weight, or resistant, etc.; but Moses called it firmament by comparison with the most tenuous bodies, and because it may easily be grasped by the senses.* In homily 1 on the Hexaemeron, however, he had taught that the nature of the heaven is declared by Isaiah to be tenuous and not at all solid, in these words: *The heaven was made firm like smoke, etc.* — words I shall report in chapter 7, number 13.

[Margin: St Nyssen.] With him his brother St Gregory of Nyssa is in remarkable agreement, in *De historia sex dierum*: *I for my part judge that no body dense, thick, solid, resisting and hard, etc., is to be considered in the firmament, but the extremity of sensible nature; and that it is called firmament by Scripture by comparison with the everlasting, incorporeal property that escapes touch. For who does not know that whatever is solid and firm has been thoroughly condensed and consolidated by a certain hardness? But what is dense and hard is not empty and free of the quality of weight and heaviness; and what is heavy cannot naturally be carried to the regions above.* [Margin: St Ambrose.] St Ambrose subscribed to the same St Basil, book 2 of the *Hexaemeron*, chapter 2, but has these points of his own: *Firm is everything that God has established*; and further on he asks: *How was the firmament solidified among the waters? They flow forth, it is bound fast; they run, it remains*; and he answers that this was done by divine power and might. And in chapter 4: *From firmness, then, the firmament was named, or because it was made firm by divine might, as Scripture teaches us, saying: Praise him in the firmament of his might.* But in chapter 6, speaking of the heaven which Isaiah compares to smoke, he says: *wishing to declare its nature subtle and not solid.* [Margin: St Augustine.] And St Augustine too, book 2 of *De Genesi ad litteram*, says: *For one may understand the firmament to be so called on account of its firmness, or on account of the impassable boundary between the upper and the lower waters.* These very words were copied out by Eucherius, book 1 on Genesis; by Bede, in the book on the creation of the six days; by the Gloss, both the ordinary and the interlinear, that is, Strabus and Anselm; by Hugo Carensis in the *Postills*; and by the Master, both of the *Sentences*, on book 2, distinction 14, and of the *Scholastic History*, chapter 4 — granted that these authors do not deny any heaven all solidity.

[Margin: Albertus Magnus.] In another way, namely as incorruptibility, Albertus Magnus interpreted this firmness, part 1 of the *Summa de quatuor coaevis*,

question 4, article 19: *The firmament is so called from the firmness of its nature, because it is neither generated nor corrupted.* And he takes the harmony of the heaven for a tempering of qualities that are not at all in conflict, and adds: *For this harmony prevents the harmfulness of each one by itself; and on this account it is called firm, because that harmony is indivisible, since it is drawn out beyond the action and passion of contraries.* [Margin: Tostatus.] Likewise Tostatus [Alonso Tostado], in his Commentaries, or notes, on Genesis: *That whole heaven is named from firmness, because the celestial substance is firm and lasting.* And although he adduces that saying of Elihu in Job, *Which are most solid, as if cast of bronze*, he nevertheless adds: *But in Hebrew that whole celestial body is called Raquin, which signifies expansion, not firmness, etc.; and it is called the expanse because it is spread out over the whole world, covering all things.*

[Margin: St Damascene.] But I return to the more ancient authors. Among them St Damascene, book 2 *On the Faith*, chapter 6, makes no mention of solidity; for he had said: *Then God called heaven the firmament, which he commanded to be made in the midst of the waters, bidding it divide the half of the water that is above the firmament from the half that is below the firmament. Its nature St Basil, taught by divine scripture, said is tenuous, like smoke; others, however, say it is watery, because it was produced in the midst of the waters; others, that it is of the four elements; others, a fifth body different from them.* [Margin: St Cyril of Jerusalem.] Before him, St Cyril of Jerusalem, Catechesis 9, assumes the heaven to be pervious and penetrable to waters, saying: *He set the waters above the heavens, so that when the earth needed the watering of rains, this heaven might be ready by nature for it.*

I admit, however, that, St Basil and St Gregory of Nyssa excepted, the following testimonies are clearer for the fluidity of the heaven, resting as they do on the immobility of the whole heaven, at least of the planetary one, and on the motion of the stars within it. [Margin: St Justin.] St Justin, question 39 of the *Questions to the Orthodox*: *How is it that those who say this speak truly, when the stars are carried not in the heaven but below the heaven? If we say they are in the heaven, how do they have the power and action of moving, when the celestial body is immobile?* [Margin: Eusebius of Emesa.] In what sense he is to be understood we shall learn from Eusebius of Emesa, in Lippomanus, in the Catena on chapter 1 of Genesis and the work of the fourth day: *It is asked whether the luminaries and stars complete their course at a distance below the heaven, or are fixed in the heaven, or make their journey in the heaven like travellers.* And he answers that they are in the heaven, but not fixed, because they themselves move while the heaven is unmoved; and he concludes: *Sacred and divine scripture therefore testifies that the heaven is firm and immobile, but that the Sun and Moon move in the heaven and complete their course. For in Joshua it is said: Sun and Moon, stand still; it does not say: Heaven that moves the Moon and the Sun, stand still. Likewise to Hezekiah it is said: Let the Sun go back; it does not say: Let the heaven that moves the Sun go back.*

[Margin: St Chrysostom.] I find that St John Chrysostom was plainly of the same opinion, homily 6 on Genesis: *He set the stars in the firmament of heaven. What does 'set' mean? Is it as if one were to say 'fixed'? Far from it; for we see*

them cross a great space in a single moment of time, and never stand in one place, but complete their own course, which the Lord prescribes for them. And homily 14 on the Epistle to the Hebrews: *Which God fixed, and not man: where are those who say that the heaven moves? etc.* And homily 12 to the people of Antioch: *The heaven indeed has remained immobile, as the Prophet says, who set the heaven like a vault, and stretched it out like a tent over the earth; but the Sun, with the other stars, revolves daily.* [Margin: Philastrius.] Philastrius, however, presses the same opinion in weightier words, in the *Catalogue of Heresies*, heresy 46: *There is a heresy which has the stars fixed in the heaven, and does not acknowledge that, from the treasury and the hidden places of light and disposed by God, they come forth suddenly towards evening at the divine command, and at the appointed hours fulfil with their light the course and ministry enjoined on them. This is found contrary and alien to the Catholic faith, if anyone should think so, and it will be shown to have fellowship with pagan vanity and the empty wisdom of the Philosophers rather than with Christian knowledge.*

[Margin: Procopius.] Let Procopius add his vote to these, on chapter 2 of Genesis, where, to the question put forward — *whether the luminaries revolve fixed in the heaven, or complete their revolutions while the heaven stays stable and immobile* — he gives a satisfactory answer: *As it seems to me, the luminaries proceed through the space of the heaven, extending all their light to us. For not in vain does Scripture have, God set them in the firmament; nor is the word 'set' to be understood, as some will have it, for 'fixed'. Therefore also Jesus son of Nave cries out: Sun, stand still; and he did not say: Heaven, stand still, which moves it.* [Margin: Diodorus.] The mind of Diodorus of Tarsus, on Genesis, was without doubt the same; Lippomanus also reports it in the Catena: *Let no one, he says, when he hears 'and he set them in the firmament of heaven', suppose that the Sun, Moon and Stars are fixed in the heaven and the heaven moves, bringing a gentile dogma into the Church.* And he adduces the example of Adam, whom God set in paradise but did not fix; and he goes on: *Therefore it must be understood that, just as men are set on the earth, so the luminaries are set in the heaven, completing that celestial journey.*

[Margin: St Augustine. Isidore.] To these must be joined those who thought that the non-wandering stars are indeed fixed in the firmament, but that the Planets move in it, or in the aether contained beneath it, by themselves, and not with the motion of the orb. St Augustine seems to approve this, book 2 of *De Genesi ad litteram*, chapter 10, and Isidore, book 3 of the *Etymologies*, chapter 49: *They say that the Sun moves by itself. For if it remained fixed to the heaven, all days and nights would be equal; but since we see that it will set tomorrow in one place and set yesterday in another, it is apparent that it moves by itself, and does not turn with the world.* Nor indeed, if anything was mistaken by him or by others in astronomical subtlety, does it harm us; for it is enough if we prove what we intend from the authority of the Fathers — namely, that the Planets do not move with the motion of the or- b; [Margin: Richardus Victorinus.] and so does Richardus Victorinus, book 2 of the *Excerptions*, chapter 7: *On the fourth day he made the luminaries, which are shown to be fixed in the firmament, except for*

the seven Planets, whose names are these: Moon, Venus, Mercury, Sun, Mars, Jupiter, Saturn. By the name of luminaries he means the lights of the stars. [Margin: St Anselm.] But St Anselm of Canterbury, book 1 of *De imagine mundi*, chapter 24, speaks admirably to our purpose: [Margin: Fire, or aether, as the heaven of the Planets.] *Fire, which is enrolled as the fourth element, is so called as if "not begetting"; it extends from the Moon up to the firmament, and is as much subtler than air as air is thinner than water and water rarer than earth. This is also called aether, as if pure air; it rejoices in perpetual splendour. From it the Angels take bodies when they come, sent to men. In it seven stars are carried, each in its own circle, against the world, and on account of their wandering course they are called Planets, that is, wanderers. These are swept along by the immense speed of the firmament from East to West, yet are shown to go by their natural course against the world, like a fly on a millwheel.* Yet the same author, in chapter 25, as we reported in number 3, teaches that the firmament in which the non-wandering stars are is solid, like crystal. [Margin: Iunilius.] Iunilius had taught the very same thing long before, in his *Hexaemeron*: [Margin: Aether for heaven.] *It must be understood that the birds fly along the firmament of heaven because the aether too is indicated by this name: that is, that upper space of air which reaches from this turbulent and murky place, in which the birds fly, up to the stars, and which is believed, not without reason, to be wholly tranquil and full of light. For the seven wandering stars, which are said to be carried wandering in this space of aether, scripture has said are set in the firmament of heaven.*

[Margin: Dionysius Carthusianus.] Dionysius Carthusianus likewise reports another opinion and does not disapprove of it, in his exposition on Genesis, article 12: *Here the firmament is taken for the starry heaven, or Eighth sphere*; and presently: [Margin: Plato. Ptolemy.] *Plato in the Timaeus says that the stars are not fixed in the firmament but travel and lead a dance in it; and in this Ptolemy followed Plato. Hence they say that it is not the heaven but the stars of the heaven that move and are carried around.* [Margin: Rupertus.] Finally Rupertus, book 1 on Genesis, chapter 23: *Nevertheless we do not go so far in agreeing that there are waters above the firmament as to grant that they are also congealed.*

[Margin: 2nd argument: from the fact that the motion of the Planets is never granted to the heaven.] V. The second argument from the scriptures is taken from negative authority, which has great force in this place: on the contrary, motion is attributed to the Sun and to the Moon, whereas the motion of any of the Planets is never read in sacred scripture as ascribed to the heaven. For whenever there is talk of the rising or setting of the Sun, it is always attributed to the Sun, as in Genesis 19: *The Sun was risen upon the earth*, and chapter 32: *And immediately the Sun rose upon him.* So too the Sun itself is said to go down or set: Leviticus 32, Judges 19, 2 Paralipomenon 18, Tobit 2, and Joshua 10: *Sun, do not move against Gabaon, and you, Moon, against the valley of Aialon; and the Sun and the Moon stood still, etc.* Of this same miracle, 1 Paralipomenon 4: *Who made the Sun stand still*; and Ecclesiasticus 48: *In his days the Sun went back.* Of that other miracle, worked on the dial of Achaz, book 4 of Kings, chapter 20,

and Isaiah 38: *And the Sun returned ten lines by the degrees by which it had gone down.* So in Job 9 we have of God: *Who commands the Sun, and it does not rise.* And Psalm 103: *The Sun is risen, and they are gathered together.* And Ecclesiastes 1: *The Sun rises and sets, and returns to its place, and there, rising again, circles through the South and bends towards the North; surveying all things round about, the wind goes on, and returns to its circles*; and Matthew 5: *Who makes his Sun rise upon the good and the bad.* Search diligently, then, and turn over the sacred pages: you will never find motion attributed to the heaven, such that the Sun or Moon might be understood to move with its motion, but only to the Sun and the Moon.

[Margin: Mutual penetrability of the celestial bodies.] Either, therefore, the celestial globes penetrate one another together with the heaven, and do not have the impenetrability that the other bodies below the Moon have — which some have conceded, as reported, and not refuted, by Albertus Magnus, part 1, question 4, article 19, and by St Bonaventure on book 2, distinction 14, part 2, article 1, question 2: *As light passes through air*, says Albertus; or because *A body of light can be together with another light*, as St Bonaventure says; and which others admit, who are to be reported in chapter 7, number 6. Or else it must certainly be said that, the heaven being for the most part unmoved, the Planets move through it as birds move through the air, the part of the heaven through which they travel giving way; and that part at least must be admitted to be fluid. Or it must be said that sacred scripture expresses the motion of the Luminaries as being the one that is more manifest and strikes the eyes, as Martinengus, Pererius and Amicus say, who are to be adduced below, in chapter 7, number 13.

Quæſtio 3. An & quæ Aquæ ſint ſupra cælos ſidereos, & in quem finem vel vſum & quantæ molis ?

Question 3. Whether there are Waters above the starry heavens, and of what kind; for what end or use; and of how great a mass.

VI. Not a few have denied these waters, among them Clavius in the *Sphere*, page 45, Arriaga in the single disputation on the heaven, section 4, and all those who are to be reported below, in numbers 11 and 12. Let the CONCLUSION nonetheless be this: [Margin: 3rd Conclusion.] *Some Waters, once of the same species as the elemental waters, have been above some starry heavens from the second Day of the founding of the World down to these times.*

It is proved, first, from sacred Scripture. In Genesis 1 the Abyss is supposed to have been made on the first day, that is, a depth and great mass of waters, as is the common consensus of the interpreters, with one or another dissenting — whether those waters were then mixed with the other elements or not. Then, of the work of the second day, it is said: *Let there be a Firmament in the midst of the waters, and let it divide the waters from the waters. And God made the Firmament, and divided the waters that were under the firmament from those that were above the*

Firmament. And God called the firmament heaven. Here, in the strictness of the Hebrew language, the word *were* is not present, at least in the second place; it was added in the second place by a certain consequence or correspondence, since it could have been rendered: *those under the Firmament from those above the Firmament*: *those that were under the Firmament, from those above the Firmament*, with *were to be*, or *were*, or *are* understood. For before the Firmament was made there were no waters above the Firmament. These things premised, it is sufficiently clear that there are some waters above the firmament, and that they are of those which were joined and continuous with the waters that remained below the Firmament. Then in Psalm 148 it is said: *Praise him, heavens of heavens, and let all the waters that are above the heavens praise the name of the Lord.* And earlier, in Psalm 103: *Stretching out the heaven like a skin, who cover its upper parts with waters.* And again in the Canticle of the three youths: *Bless the Lord, all you waters that are above the heavens.* Hence those lines in the hymn for Vespers of Monday:

Immense caeli Conditor, Qui mixta ne confunderent Aquae fluenta dividens Caelum dedisti limitem, Firmans locum caelestibus, Simulque terrae rivulis; Ut unda flammas temperet, Terrae solum ne dissipent.

("Immense Founder of the heaven, who, dividing the flowing waters lest, mingled, they should throw all into confusion, gave the heaven as their boundary, making firm a place for the celestial waters and likewise for the streams of the earth, so that the wave may temper the flames, lest they waste the soil of the earth.")

[Margin: 2nd proof from the Fathers.] VII. It is proved, secondly, by the Authority of the Fathers, who are so many that Delrío says in his notes on Genesis that they have the force, as it were, of a single Council. And certainly in the sixth Synod of Constantinople the letter of Sophronius was read in action 11 and approved in action 13; in it, among the other errors of Origen, this one was reported: [Greek: ὑπερουρανίων ὑδάτων κακίζοντες (hyperouraniōn hydatōn kakizontes, "disparaging the supercelestial waters")], namely, rejecting the creation of the supercelestial waters. Moreover, we have already brought forward many of the Fathers, in number 3: namely Tertullian, Hilary, Hippolytus, Caesarius, Severianus, Cyril, Chrysostom, Claudius Marius, Procopius, Anselm, Theodoret, Iunilius, Strabus, Hugo, Comestor, and finally all who think that the heavens were made of water and made firm or solidified. [Margin: St Augustine.] But besides the passages already adduced, St Augustine, book 2 of *De Genesi ad litteram*, chapter 1, after saying: *Many assert that the nature of these waters cannot be above the starry heaven, because they have their weight so ordered that they either flow upon the earth or are borne as vapour in the air next to the lands*, then concludes, in chapter 5: *But in whatever way, and of whatever kind, the waters there may be, let us in no way doubt that they are there; for the authority of this scripture is greater than the whole capacity of human wit.* [Margin: Bede. Eucherius.] Eucherius and Bede on Genesis bring forward and approve this very opinion in as many words. But again St Augustine, book 11 of *The*

City of God, chapter 34, teaches that this is no more to be wondered at than if someone should say that the seat of Phlegm, or pituita, is in the head of man: if we did not know this, and scripture said it, it would not be believed by certain Philosophers who are moved by the weights of the elements, and whom he there calls *weighers of the elements*. And expounding Psalm 103, on the words *who cover its upper parts with waters*, he says: *And this is read, and according to the let- ter, is understood: for when he commanded that a firmament should be made between waters and waters, it came about that there are lower waters, which flood the lands, and upper waters, removed from sight yet commended to faith.* [Margin: St Prosper.] St Prosper copied out and adopted this opinion, on Psalm 103: *Therefore, although the eye of the body does not discern them, the eye of faith can reach them.* [Margin: St Clement.] Indeed St Peter, as Clement has it in book 1 of the *Recognitions*, after saying that part of the waters was solidified into heaven, added: *After this, what was left of the waters in the lower regions the place of the sea received, by the command of the eternal will.* He therefore supposes that those waters are of the same nature as the other waters. [Margin: St Hilary.] So too does St Hilary, on Psalm 135, when he says: *For by the waters raised up he tempered that very nature of the first heaven.*

[Margin: St Basil.] And St Basil too, homily 3 on the Hexaemeron, after teaching that an abundance of the upper waters was necessary for tempering fire, and after reporting the fictions of Apollinaris and Origen, who understood by the waters above the heavens either Angels or something of that kind, says: *Setting aside, then, these opinions and those of that kind, as being like dreams and old wives' tales, let us understand water as water*: that is, according to the letter, with this name taken in its common sense. In the same place, to those asking how fluid waters can stand upon the spherical surface of the heaven, he had answered that, although the concave surface of the heaven is, or seems, round, the convex surface is not necessarily round, but can have the shape of a vessel containing waters. [Margin: St Ambrose.] St Ambrose took this very point from Basil, book 2 of the *Hexaemeron*, chapter 3, against those who, as he himself puts it, *want to destroy what has grown habitual in our minds and been impressed on them by frequent reading of the scriptures, because waters cannot be above the heavens, saying that that orb of heaven is round, etc.* And a little after, having dismissed them, he adds: *But we follow the sequence and order of the scriptures, and contemplate the work by the judgement of its author, etc. I hear that the firmament is made by a precept by which the water should be divided and the upper separated from the lower. What is clearer than this? He who commanded the water to be separated by the Firmament set between them in the middle provided for how, divided and separated, it could remain so.* Then, pouring himself out in praise of the divine omnipotence, he concludes: *When you hear these things, why do you wonder if, above the firmament of heaven, water could be suspended by the working of so great a majesty?* He confirms this from the waters of the Red Sea and of the Jordan, poised on either side in heaps and held suspended until the people of God passed over dry-shod; from the waters bound in the clouds; and from the swelling of the sea, which does not

flood the land. And in chapter 4, after adducing the opinion of Origen, who interpreted the name of Waters as an intellectual, or Angelic, nature, because those waters are invited to praise God, he added: *To us, however, it seems neither alien nor absurd if we understand true waters, for the reason we have given. For dew and frost, and cold and heat, bless the Lord according to the prophetic hymn, and we do not refer these to intelligible natures, but to reality.*

[Margin: St Epiphanius.] Epiphanius recounts the same error of Origen in his letter to John, Bishop of Jerusalem, and refutes it, saying: *And how do we read that in the flood the cataracts of heaven were opened, and the waters of the flood overflowed?* [Margin: St Chrysostom.] We heard St John Chrysostom above, in number 3, but we must hear him again, homily on Psalm 148, on the words *And all the waters that are above the heavens*: *You have heard Moses too saying that, of the waters, he left these below, but made those stand on high upon the celestial ridges, when he had established the firmament in the midst of the abyss.* [Margin: Theodoret.] To him I join Theodoret, question 11 on Genesis, who speaks thus: *God divided the nature of all the waters in two: some he placed above, which by their moisture and coldness would not allow the firmament to be corrupted by the fire of the luminaries; the remaining waters stayed below, to nourish with their vapours the air, scorched and dried by the fire above.* [Margin: St Damascene.] St Damascene, book 2 *On the Faith*, chapter 6, should also be read; he teaches expressly that these waters are above the firmament. [Margin: And Chlichtovaeus.] So does Iudocus Chlichtovaeus [Josse Clichtove], his commentator, who, although he takes them for the ninth heaven, nevertheless admits that Damascene thought otherwise, when he adds: *Or there really are thin and transparent waters, standing above the firmament that is adorned with so great a multitude of stars, by the precept of the founder, and for a reason which the founder himself knows, though it is hidden from us — as the sacred writings seem to hold in very many places, and Damascene here.* [Margin: Procopius.] Moreover, having reviewed the opinions of many, Procopius, chapter 1 on Genesis, concludes: *They say that the Firmament is called heaven either because it is concreted and compacted from the most simple nature of water, or so that it may distinguish and separate from the lower ones a most tenuous and most light nature, comprehensible by no sense. In saying "in the midst of the waters", he teaches clearly enough that the division of the waters was equal on each side.*

[Margin: Bede.] We named Bede above as subscribing to St Augustine; now let us adduce him again, from the book *De natura rerum*, chapter 8, differing thus: *The waters set above the heaven are lower indeed than the spiritual heavens, that is, the Empyrean and the Angels, but nevertheless higher than every corporeal creature. Some affirm that they are kept for the flooding of the deluge; others, more rightly, that they are suspended to temper the fire of the stars.* And in the *Questions on Genesis*: *Let the heretics at last cease their madness and, confounded, acknowledge that he who could create all things out of nothing could also establish that nature of the waters in the heaven with an icy solidity. For since they themselves say that the orb glittering with burning stars revolves, did not divine providence necessarily see*

to it that water should overflow within the orb of heaven and above the orb, to keep apart those blazing fires of the axis? [Margin: Cassiodorus.] Let Cassiodorus follow him, although he is older, on Psalms 103 and 148, where, supposing these waters, he adds the cause: *So that the tenuity of the heavens may stand firm, and the waters placed above the firmament, though they are heavier, may not flow down except when they are commanded.* [Margin: Haymo. St Bruno.] But most acutely Haymo and St Bruno, on the same two psalms, have those waters praise God — that is, rouse us to his praise — for this very reason: that, though they are true waters, they are nevertheless held there, even if their use is hidden from us. [Margin: Remigius.] Most simply, however, Remigius of Auxerre, on Psalm 148: *That there are waters above the firmament is clear from Genesis, where it is said: he divided the waters, etc.*

[Margin: Rupertus.] Now let Rupertus the abbot come forward for us, book 1 on Genesis, chapter 23: *Others of the Doctors want nothing else to be understood by the name of the waters that are above the firmament than waters, simply. Their opinion is without doubt the more just and the safer, namely, that the sense should not disagree with the letter of the sacred history.* Yet he denies that they were congealed; and in chapter 24 he teaches that the firmament is like the roof of the vault of heaven; and in chapter 25: *And it is indeed a wonderful work of the magnificent God that the subtle nature of the firmament, spread beneath, sustains the mass of the waters.* He confirms this by the example of the air and the water that sustain the mass of the earth on every side; and in chapter 31: *The waters that are below the firmament are surely remnants, or a part, of the waters that are above the firmament.* [Margin: St Anselm.] St Anselm of Canterbury, book 1 of *De imagine mundi*, chapter 28, thought them attenuated after the manner of a cloud, saying: *Above the firmament are waters suspended like a cloud, which are said to encircle the heaven round about; hence it is also called the heaven of waters; above it is the spiritual heaven, etc., and the Paradise of paradises.* In chapter 25, however, he set the firmament itself as solidified like crystal, as I reported in number 3. [Margin: Hugo Victorinus.] But Hugo Victorinus chose half of this opinion, in his annotations on Genesis, chapter 6: *That there are waters above the firmament is held both in Genesis and in the Prophet, etc. But what those waters are like is not certain to us. Some, however, say that they are solidified there in the manner of ice; but it has seemed more likely to me that they stand there suspended as vapour, after the likeness of a vapour, that is, of smoke or cloud.*

[Margin: Comestor.] Petrus Comestor, in the *Scholastic History*, chapter 4, plainly holds the contrary, but under a disjunction: namely, that both the Firmament and the waters above it congealed in the manner of ice. For after asserting: *Truly the firmament divides the waters that are below it from the waters that are above it*, he added: *and they, like it, are congealed like crystal, so that they cannot be melted by fire; or else they are vaporous in the manner of a cloud.* [Margin: Hugo Carensis.] Hugo Carensis used almost the same words in the *Postills*, saying of the waters above the firmament: *And these waters are congealed after the manner of crystal, so that some call them the crystalline heavens; or they are vaporous after the*

manner of a cloud. [Margin: Oleaster.] Prudently, Lusitanus, or Hieronymus ab Oleastro, on chapter 1 of Genesis, on these waters: *Since scripture everywhere cries out that they are there, many Theologians prefer to follow the blind Philosophers rather than the authority of scripture, etc.* And having adduced other authorities of scripture, he concludes: *I would rather, then, err with scripture (if it could err) than speak the truth with the Philosophers.* And presently: *I think, however, that they are elemental and of the same nature as the lower ones; for before, as is clear from the text, they were continuous with the lower ones; and once the firmament, or the division, had been made, they do not seem to have changed their nature.* It is my pleasure on this occasion, against those who neither the Divine scriptures nor the interpretations of the Fathers hold in reverence, to report a judgement full of gravity from Bishop Vielmius, lecture 14 on Genesis. [Margin: Vielmius.] There, after setting out the objections against waters of this kind — as though they were above the heavens both to no purpose and by violence — he says: *Rightly indeed, etc., were it not that the word of God stood in the way, especially as interpreted by nearly all the ancient saints, who understood from these words that waters of one kinship and nature with ours are placed and exist above the heavens.* And after bringing forward the words of Genesis he adds: *But we Christians are at this time in such a calamity that many of our own (if indeed they deserve to be called our own) grow used, from the first flower of youth, not to stand in awe of holy antiquity.* Moreover, Claudius Marius Victor, whom we have already cited for a solid heaven in number 3, judged that the quantity of those waters is great; for he sings:

And that a great sea is borne above the stars and constellations, prove it by the reasoning of those very men who refuse to believe it, and want the World to hang.

For brevity's sake I now pass over many more recent writers on Psalm 103, at the verse *You who cover its upper parts with waters*, and on Psalm 148, at the verse *And all the waters that are above the heavens*. [Margin: Authors who place in the heaven waters different from the elemental ones.] Granted that St Gregory of Nyssa, in the *Hexaemeron*, said that these waters are of a different nature from the elemental ones, lighter than fire and devoid of all sensible qualities; and granted that many who assert the incorruptibility of the heaven appear to recognise that difference from the elemental waters — and with them Alensis [Alexander of Hales], Albertus, Scotus, Durandus, Bonaventure, Aegidius, Catherinus, Petrus de Tarantasia, and St Thomas in the *Disputed Questions*, q. 4 ad 5, on book 2 [of the *Sentences*], d. 14 q. 1, and in the First Part, q. 68 art. 3 ad 1. For he teaches that these waters resemble crystal in their solidity and water in their transparency, but are of a different species. With them our Tanner agrees, tome 1 of his *Theology*, disputation 6, q. 3, doubt 1, where in assertion 10 he concludes that by the name of the waters above the heavens is most probably to be understood the Empyrean, or a simple celestial body, transparent, liquid and breathable, destined for the dwelling of the Blessed. Gulielmus Parisiensis held the same, part 1 of *De Universo*, chapter 39. But surely he would rather have called it air than water, since air is better suited to breathing.

VIII. From the authors adduced, then, one may gather four opinions on the condition of these waters. [Margin: 1st opinion, on the quality of these Waters.] The first view — later in time, however, than many — was that they differ in substance from the elemental waters. We adduced its authors a little earlier, and it is indeed hardly consistent with the literal sense of Sacred Scripture, or with most of the Fathers already cited in numbers 3 and 7. [Margin: 2nd opinion, of waters thinned into vapours, and its authors.] The second holds that those waters are indeed of the same kind in substance, but rarefied and spread above the Firmament after the manner of a vapour or cloud — much as we see, from high mountains, a misty air besieging cities and towns, or thin vapours and smokes lying over valleys and standing waters, or the whole surface of the horizon covered with dewy mists. As a result of this lightness, even if they had no solid firmament beneath them, they could nevertheless remain suspended there, in the same way as vapours and mists above our air. So thought St Augustine, *De Genesi ad litteram* book 2, chapter 4 — especially on the supposition of a rarefaction possible finitely to infinity, and of the view of those who assert: *All things are divided infinitely, since every part of a body is a body, and every body must have half of its quantity. And therefore, if water can, as we have seen, reach droplets so minute that it is borne as vapour above this air, which is by nature lighter than waters, why could it not also remain above that lighter heaven in more minute droplets and lighter vapours?* Subscribing to him were Eucherius, book 1 on Genesis, chapter 3, who says: *For just as these clouds, which are everywhere, are borne above the air, which is the third element, so I think it can happen that thin and subtle waters are borne above the heaven*; the Master, on book 2, d. 14, using St Augustine's very words; and also St Anselm, both Hugos, and Comestor, as is clear from their words cited a little before, toward the end of number 7. To these add Anselm of Laon in the interlinear gloss, who distinguishes the upper waters from the lower by this mark: *In the midst of the waters suspended as vapour, and of those gliding over the earth* — if he is to be understood of vapours above the starry heaven. St Thomas, however, in the *Disputed Questions*, q. 4 art. 1 ad 5, refutes this opinion on the ground that water cannot exceed the degree of rarity proper to water: *Nor could it*, he says, *naturally go beyond the spaces of fire and air, unless it had lost the nature of water and surpassed their rarity.* And certainly clouds and vapours, however thin, have exhalations and spirits mixed into them, and with these they make up a body lighter than air taken in a bulk equal to their own magnitude; and that is why they fly above the air. But St Thomas spoke of what happens naturally. For God could have spread out the waters, thinning them so that they were rarer than the ethereal air itself, and yet have willed not to withdraw his conserving concurrence from the original substantial form of water — and indeed from its coldness and moisture as well. Of the Doctors already mentioned, however, St Anselm, Comestor, Hugo Carensis and the Master admitted a Firmament solid like ice or a vault, as is clear from what was said in number 3.

[Margin: 3rd opinion, of liquid waters above a solid Firmament, and its authors.] The third opinion was that these waters are liquid and flowing, in the way the other elemental waters flow, and that they do not slip down because they are held up by the back of the firmament. Of this opinion were Tertullian and Saints Basil, Ambrose, Hilary, Caesarius, Cyril, Chrysostom, Hippolytus of Portus and Anselm; likewise Clement, Theodoret, Iunilius, Procopius and Strabus. Nor did St Augustine, Hugo Victorinus and Comestor reject it, as will be plain to anyone who rereads their words quoted by us from number 3 to number 8. Of these, some think those waters do not flow away because they are enclosed in vessels and outermost hollows of the highest heaven; others attribute this to the power of divine Omnipotence. But it could be added that, for this, it suffices or contributes both that they are at an equal distance from the centre of the World, and that there is a rapidity — either of the Firmament, lest they be carried round by it, or their own, if that watery heaven is taken as the primum mobile. For we see that water in a vessel spun very fast up and down does not flow out. Or else they do not gravitate there, because they are outside the sphere of the elements, as Oviedus says in his *Physics*, page 466.

[Margin: 4th opinion, of waters merely congealed, and its authors.] The fourth opinion seems to have been that of those who judged both the waters above the heavens and the Firmament itself to be solid after the manner of crystal or ice, as though admitting twin crystalline heavens; or who certainly recognised no waters other than the Firmament itself, consolidated like ice, or at least its upper part. In that way both things are true: that through it the waters are divided from the waters, and that they do not fall down because they have congealed into that hardness. So, it seems, thought Josephus the Hebrew, Pope Clement and Severianus, adduced in number 3. Strabus admitted it in the ordinary Gloss, in these words: *He was able to suspend the waters not by bodily thinness but by icy solidity*; and Anselm of Laon in the interlinear gloss, saying: *The upper part of the waters is congealed like crystalline stone; the lower is gathered into a womb.* And Bede, in the book *De natura rerum*, chapter 7: *We think, however, that the nature of the waters there now hangs not by vaporous thinness but by icy solidity, in order to temper the natures of the stars.* But no one, so far as I know, set out two crystalline heavens more distinctly than Comestor, *Scholastic History* chapter 4, when he said of the firmament and the waters above it: *And they, like it, are congealed like crystal* — granted that he did not deny that they could be thinned out like a cloud. Into this class can be placed those who, as Hamerus reports in his *Commentary on Genesis*, understand by the upper waters the crystalline heaven, so called for its hardness and transparency; by the lower waters, the heaven of Saturn; and by the firmament, the Aplanes [the sphere of the fixed stars]. Our Clavius too, on chapter 1 of the *Sphere*, formerly page 45, says that no one of sound judgement understands that there are flowing and falling waters above the heavens, like these lower ones; rather, the ninth and tenth heavens are to be understood, which are called waters for their transparency and uniform rarity, and by others crystalline or glacial. So

too Cajetan, on 2 Corinthians chapter 12, says that the watery heaven is the primum mobile, which he calls the third heaven; and Io. Antonius Delphinus [Giovanni Antonio Delfino], *De caelestibus globis* page 62, that those waters are the ninth, crystalline heaven, or primum mobile.

IX. [Margin: The quantity of the Waters above the heavens.] But you will ask how great that quantity of waters above the heaven is. I answer that this is most uncertain. Some, however, moved by the phrase *let there be a firmament in the midst of the waters*, judged that half of the whole abyss — that is, of the water created on the first day — was left on the earth, and the remaining half passed into the heaven by expansion or solidification. So hold Severianus, Damascene and Procopius, already adduced from number 3 to number 7, and Theophilus, to be reported in number 10. But

St Hippolytus thinks that a third of them was left on the earth, a third driven together into the firmament, and a third placed as waters above the heavens.

X. [Margin: The end and use of these waters.] The end for which the waters already mentioned were carried up into the heaven is said by some to be unknown, and known to God alone. Others think they are reserved there for the dew that drips upon the earth, as Comestor reports from the opinion of others, *Scholastic History* chapter 4, saying: *Why they are there, God knows; except that some hold that dew comes down from there in summer.* Others think they are reserved for rains, especially at the time of the flood, and that these are the Cataracts of heaven which are said to have been opened then, Genesis 7, and of which it is said in Malachi 3: *If I will not open to you the cataracts of heaven.* So the Master, on Psalm 103, says of these waters: *They flow down through rains only when commanded; as is said, they are sent down through rain when the cataracts of heaven are opened.* The same is held by St Epiphanius in the letter to John, Bishop of Jerusalem; by Cyril of Jerusalem, Catechesis 9; by Cassiodorus, Richardus and Haymo on Psalm 148; by Lusitanus on chapter 7 of Genesis; before these by Josephus, *Antiquities* book 1, chapter 1; and by Theophilus of Antioch, book 1 *To Autolycus*, who says: *The second heaven, this visible one, has been called the firmament; it carried up half of the water, so that for the use of men it might pour out rain, showers and dew.* Some hold that the waters were placed there to make the heaven firm, unshaken by the storms of the winds — for St Justin too counts this among the other causes, q. 93 of the *Orthodox*; some, to chill the star of Saturn and to preserve cold influences in the World, from the same Justin in the same place; others, to drive the rays of the stars back downward: *For fire by its nature tends upward*, says Procopius in his *Commentary on Genesis*; *therefore water is joined to the highest heaven, to thrust and drive the brightness down to the lowest parts.* Others hold that they blunt the heat of the first, or Empyrean, heaven: so St Hilary on Psalm 135, and Bede, in the book *De natura rerum*, chapter 7. Others, that by the variety of visible forms which crystal and water can receive from the light of day, as appears in the Rainbow, they refresh the eyes of the blessed — as Cornelius à Lapide teaches, on no slight conjecture, on the Pentateuch at the second day of the world, and Salian in

the *Annals* at the same day, number 20. Very many, however, hold that those waters were carried up into the heaven for this end: to temper the heat of the stars and of the aether, and to preserve heaven and earth from burning. This is taught by St Justin as well, question 93 of the *Orthodox*; St Basil, homily 3 on the *Hexaemeron*; St Ambrose, *Hexaemeron* book 2, chapter 3; St Damascene, *On the Faith* book 2, chapter 9; Theodoret, question 11 on Genesis; Procopius on Genesis, chapter 1; Bede, *De natura rerum* chapter 8, who prefers this opinion to the others; St Thomas in the postills on Genesis; Claudius Marius Victor, commentary on Genesis; and the Church herself, in that hymn:

That the wave may temper the flames, lest they scatter the soil of the earth.

But perhaps they are there so that by their own motion they may perform the office of the 24-hour motion, that is, of the primum mobile, as we shall say below, section 2, chapter 3.

Quæſtio 4. An Aquæ ſuperiores ſint Angeli Sancti ?

Question 4. Whether the upper Waters are holy Angels.

XI. From what has been said so far it is sufficiently clear that the Waters which sacred scripture teaches are above the heaven are some watery body: either of the same nature as elemental water, as we taught with the more common opinion from number 6 onward, or at least agreeing with it analogically in their transparency, and with the hardness of crystal. [Margin: Origen's error.] From this — and above all from sacred scripture understood, as is right, according to the letter — it is clear that the fiction of Origen deserves to be hissed off the stage. He said that the waters above the heaven are good Angels, and those below the heaven evil demons, because it was said of the upper waters that they should praise the name of the Lord. But this error, destructive of the literal sense and of sacred history, is refuted by St Basil, homily 3 on the *Hexaemeron*; St Ambrose, *Hexaemeron* book 2, chapter 4; St Epiphanius in the letter to John of Jerusalem; St Augustine, *De civitate Dei* book 11, chapter 34; St Thomas, 1 p. q. 68 art. 2; likewise Procopius, chapter 1 on Genesis; and Rupertus in the same place, book 1, chapter 23; and, among more recent writers, Pererius, book 1 on Genesis, page 63; Suarez, *De opere sex dierum* book 2, chapter 4; Martinengus in the *Glossa magna*, page 626; and Tanner, tome 1 of his *Theology*, disp. 6 q. 3 doubt 1. Without prejudice to the sense of the letter, however, those waters can be taken mystically, or figuratively, for Angels or spiritual creatures, as Saints Nyssenus [Gregory of Nyssa] and Jerome did on Psalm 76, adducing *The waters saw you, O God*, and that of Apocalypse 17, *Many waters, many peoples*. So did St Augustine, in the unfinished book *On Genesis*, chapter 8, and *Confessions* book 13, chapter 32 — although, lest this give anyone a handle for error, he retracted it, *Retractations* book 2, chapter 6.

Quæſtio 5. An Aquæ ſuperiores ſint Nubes ac Vapores ſupra Aerem vel in Aere ?

Question 5. Whether the upper Waters are Clouds and Vapours above the Air, or in the Air.

XII. It has seemed to some that elemental Waters are unfittingly placed above the heavens, especially the incorruptible ones, since they are a heavy, gross body, less noble than air; indeed, that they are placed there to no purpose and for no probable use, or even against their own nature, against the order of the elements and the heavens, and finally against the seemliness of the divine workmanship; and lastly that, if they are asserted to be non-elemental so as to avoid these difficulties, it is maintained without any valid foundation that the waters there are of a different species. They therefore went so far as to say that by the name of the waters above the heavens are to be understood the waters contained, as to their substance, in the clouds, vapours and mists that are in the highest or the middle region of the air; and that the Firmament, in this place, is the aerial heaven — the whole region composed of air and aether up to the stars, spread between those waters and the waters of the sea and the rivers as a firm and stable boundary. This opinion is indicated, and judged not wholly improbable, by St Thomas, 1 p. q. 68 art. 2 and 3; by Durandus on book 2, dist. 14 q. 1; and, following St Augustine, *De Genesi ad litteram* book 2, chapter 4, by Eucherius, Bede and the ordinary Gloss on Genesis. Indeed Abulensis, in the postills, and Vielmius, lecture 14, attribute it to the Rabbis and to Abenezra [Ibn Ezra]. It is defended tooth and nail by Rupertus the Abbot, *De operibus Trinitatis* book 1, chapter 22; Eugubinus [Agostino Steuco] in the *Cosmopoeia*; Arias Montanus [Benito Arias Montano], Lorinus, Pineda, Pererius, book 1 on Genesis from page 65; Gregorius de Valentia [Gregorio de Valencia], 1 p. disp. 5 q. 3 point 2; Suarez, *De opere sex dierum* book 2, chapters 4 and 5; Torniellus in the *Annals* at the 2nd day of the world; and Kepler in the introduction to the *Commentaries on Mars*.

For they try to show that the air can be called the firmament from Proverbs 8: *When he prepared the heavens I was present; when he made firm the aether above, and balanced the fountains of waters.* In the Hebrew, in place of "aether", there stands *Sekakim*, which properly means clouds, so that the Septuagint translated it τὰ ἄνω νέφη [Greek: ta anō nephē, "the clouds above"], that is, the upper clouds. Consequently, they say, the fountains of waters which the Wisdom of God then balanced were the upper fountains of the clouds, or the cataracts of heaven, of which Genesis 7 and Malachi 3 speak; and they say that the passage of Job 26 is to be understood of the clouds: *Who binds up the waters in his clouds, so that they do not burst out downward all together* — especially since Pliny the Elder himself, book 31, chapter 1, said: *What is more wonderful than waters standing in the heaven?* Finally they try to drag in here the passage of Jeremiah 10: *At his voice God gives a multitude of waters in the heaven, and raises mists from the ends of the earth.* Finally, they hold that the space which is now between the earth and the Moon

was formerly full of watery and misty matter, according to Job 38: *Who shut up the sea as with doors, etc., when I made the cloud its garment, and wrapped it in darkness as in swaddling-bands?* and Wisdom 24: *I made in the heavens that an unfailing light should rise, and like a mist I covered all the earth*; and that this matter was easily converted into air. Nor are Fathers lacking who champion this opinion: for St Augustine, *De Genesi ad litteram* book 2, chapter 4, said that it was *praiseworthily devised, and not against the faith*; and Bede approved it, *De elementis Philosophiae* book 2. [Margin: Authors against this opinion.] But Catherinus rejected it, on chapter 1 of Genesis; and so did Martinengus in the *Glossa magna*, page 566, saying that it is supported by no arguments; on page 585, adhering to the Fathers, he judges erroneous the opinion of those who say that by the name of Firmament only the air is understood, and on page 589 he calls it not safe enough. Molina, disputation 2 *De opere sex dierum*, says that it is plainly false; and Tanner, tome 1, disp. 6 q. 3 d. 1, says that the opposite is the common view of the Fathers, and in the dissertation *On the Heaven*, q. 8, page 179, calls the opposite certain and established. [Margin: Arguments against this opinion.] Nor has it ever seemed to me very probable: first, because on the 2nd day the Sun was not yet present to raise clouds and mists; and because it was more fitting for the divine workmanship that on the first day he should create pure elements, not elements mixed with clouds; indeed, for several days there had been no rains, as Moses says in Genesis 2: *For the Lord God had not rained upon the earth, but a spring went up.* Next, the whole of that Firmament spoken of in Genesis 1, verse 4, divides the upper waters from the lower; but our air is not such, nor is it a firm interval dividing the waters of the clouds from the lower waters, since we often see clouds and mists lying upon the sea and the marshes — so much so that the common people think the clouds suck up water from there. Nor is it consistent with sacred Genesis that the firmament made on the 2nd day should be different from the Firmament spoken of on the fourth day, that is, the one in which the Luminaries and the other stars were placed, which are certainly not located in the air. Or, if the whole space from the earth to the Fixed stars is the Firmament, it would not have told us distinctly in which part God placed the stars — the upper or the lower? And if you say that they were placed in the Firmament of heaven, that is, in the part called heaven, the objection stands: for on this opinion the waters above the heavens are above the middle or the lowest region of the air; so, if this region is heaven, someone could think on Moses' authority that the stars are located in the air. But it was a far more probable undertaking, and one more worthy of God as craftsman, to create all the heavens and all the elements on the first day; then, on the second day, to make the Firmament out of condensed water — that is, at least the heaven of the fixed stars — and so to separate the Empyrean heaven from the aether and the air by a stable boundary and interval, so that this work alone was the entire business of one day; and on the third day to bring about the divisions of Land and Sea.

CAPVT III.

Chapter III.

Quot & Qui Cæli à Deo Prima & Secunda die Mundi Conditi fuerint ?

How many Heavens, and which, were founded by God on the First and Second day of the World.

I. [Margin: All the heavens created as to their substance on the first day.] FIRST CONCLUSION. *On the first day God created all the Heavens as to their substance: namely the Empyrean, the Starry and the Aerial.*

This conclusion has been sufficiently proved from scripture and the Fathers in chapter 1, question 3, from number 6 to 17, and in question 6, where we dealt specifically with the Empyrean, that is, from number 24 to 31; and from what was said there it is clear that this is more probable than that only the Empyrean and the elements were created. Nor is it against the conclusion if someone were to say that the starry heavens were made on the second day, provided he says that they were made not by creation or substantial generation, but by an expansion of rarefied water into the Planetary heaven, and by a condensation into the heaven of the fixed stars or into the crystalline and watery heaven. For by the very fact that all that water was created on the first day, and is not held to have been changed substantially afterwards, those heavens are held to have been created, as to their substance, on the first day.

II. [Margin: Which heavens were made from water on the 2nd day?] SECOND CONCLUSION. *On the second day God made from the elemental waters both the Firmament, that is, the Starry heaven, and the Crystalline and Watery Heaven — whether these two are really distinct from each other and from the Firmament, or not.*

This conclusion likewise becomes manifest from the sacred scriptures and from the very many Fathers and Doctors adduced throughout chapter 2, up to number 11. For from the eleventh onward we refuted two false opinions in particular: one about the Angels, the other about an aerial heaven and clouds founded on that day.

III. [Margin: The distinction of the Watery and the Crystalline Heaven.] THIRD CONCLUSION. *It is more probable, having regard to the authority of the Fathers, which rests on Sacred Scripture, that the watery Heaven, or the Waters that are above the Heavens, are liquid or fluid; or at least that they are really distinct from the crystalline Heaven, taken either for the whole Firmament or for its highest part.*

For in chapter 2, from number 2 to 4, we showed from Scripture and the Fathers that the Firmament was made on the second day out of water consolidated like ice or crystal; and from number 6 to 8 that there are true waters above this Firmament — whether thinned into vapours, or, as more affirm, not thinned but flowing and liquid like the elemental waters, or consolidated into ice, as we taught from number 8 to 9. Therefore those waters, which

some Doctors have also called the Watery heaven, are really distinct from the Firmament.

IV. [Margin: The upper part of the starry heaven solid, the lower fluid.] FOURTH CONCLUSION. *It is more probable that the heaven which is solid like ice or crystal is the heaven in which the Fixed, or non-wandering, stars are, or else that other heaven which God placed immediately above it; but that the heaven of the Planets is fluid.*

This conclusion is one of those that we have so far investigated most of all, with so great a gathering of authorities; and it must therefore be established by distinct arguments — and, unless I am mistaken, very strong ones.

[Margin: 1st argument.] First, then, many very weighty Fathers and Doctors say that the Firmament is solid, solidity being taken for such hardness as ice has, or crystal, or an eggshell, or the hide of a tent, as is clear from what was said in chapter 2, from number 2 to 4; and not a few recognise the same solidity in the waters placed above this heaven. On the other hand, many others no less weighty — indeed some of those who had asserted the solidity already mentioned — nevertheless teach that the heaven is not solid with a solidity that includes hardness; and others that it is fluid and permeable, as is established from what was said in chapter 2, numbers 4 and 5. Those who asserted solidity with hardness assert it chiefly so that the heaven may be fit to sustain the fluid waters above the heavens and to separate the invisible heaven from the visible. Those who contend that the heaven is fluid, and stand more evidently for its fluidity, rely chiefly on the motion of the Luminaries through a motionless heaven — a motion that Scripture never attributes to the heaven, but only to the Planets. Therefore they can be reconciled with one another in no better way than by distinguishing: granting Solidity and hardness to the highest heaven of the visible things, or to the highest part of the Firmament — since on it immediately, and on it alone, lies the burden of sustaining the hypercelestial waters and of bounding and separating the Empyrean and every invisible heaven from the visible — and granting Fluidity to the Heaven in which the Luminaries travel, and so the other Planets with the Sun as their coryphaeus, or leader. It is better to reconcile so many Fathers, since the sacred text fully permits, and indeed indicates, such a distinction, than to suppose them at odds with one another, or to abandon them, or to swerve without necessity into one of the extreme opinions.

[Margin: 2nd argument.] Second: by the same conclusion not only are very many Fathers and Theologians reconciled with one another, but also with the more recent and more expert Astronomers, as will become clear from what is to be said in chapter 7, especially toward the end. Why, then, should we not foster this alliance with every effort?

[Margin: 3rd argument.] Third: Sacred Scripture itself, as I was saying, indicates clearly enough that some heaven is hard, being fit to divide the upper waters from the lower and to preserve that separation perpetually; and we showed in chapter 2, number 2, that this is gathered from the Hebrew name

itself. But the same Scripture, when it says that the Luminaries move freely through the heaven, and never mentions any motion of their heaven, as was said in chapter 2, number 4, also indicates that at least the part of the heaven through which they are carried does not move — supposing the impenetrability of bodies, celestial ones included, which the Theologians likewise draw from the sacred scriptures, as I here suppose. Therefore the conclusion already mentioned is very consonant with the sacred scriptures, and so the more probable; and the passage of Proverbs 8, *When he made firm the aether above*, may without impropriety be understood of the highest part of the aether, solidified.

[Margin: 4th argument.] Fourth: among the Fathers who discuss the solidity and fluidity of the heaven, many speak only indefinitely; but those who speak distinctly about some part of the Firmament ascribe Solidity and hardness only to the highest starry heaven, that of the non-wandering stars, or grant to the Planetary heaven only fluidity and permeability by the Planets. Although I have already brought forward some of them, it is my pleasure nevertheless to repeat here their select words on this matter, and those of others. [Margin: St Bonaventure.] St Bonaventure, on book 2 [of the *Sentences*], d. 14 p. 2 art. 1 q. 1, calls it the common view of Physicists and Mathematicians that *the Planets move in the heaven in one continuous body, subtle and apt for motion, such as air and water are.* [Margin: St Anselm.] Clearly, too, St Anselm, *De imagine mundi* book 1, chapter 21, where he says: *The higher Heaven is called the firmament because it is a firmament between the waters in the middle. It is spherical in form, watery in nature, adorned on all sides with stars, consolidated out of waters like ice, indeed like crystal.* If it is higher and adorned on all sides with stars, then it is the one called the eighth sphere. But he himself discloses his mind in chapter 24, when he adds about the Planetary heaven: *Fire, the fourth element, extends from the Moon up to the firmament. It is as much subtler than air*

as air is thinner than water, and water rarer than earth. Here too the aether is called pure air, as it were, etc.; in it the seven stars are carried, each in its own circle, against the course of the world, and because of their wandering course they are called Planets, etc. We cited the whole passage in number 4.

[Margin: St Isidore.] With the same distinction St Isidore, *Etymologies* book 3, chapter 49, affirmed *that the Sun moves by itself, is not turned with the World, and is not fixed in its heaven*; [Margin: Richard of Saint Victor.] and Richard of Saint Victor, book 2 of the *Exceptiones*, chapter 7: *On the fourth day he made the Luminaries, which are proved to be fixed in the Firmament, except the seven Planets, the Moon, etc.* [Margin: Gulielmus Parisiensis.] The teaching of Gulielmus Parisiensis also favours us in part, where in part 1 of *De universo*, chapter 34, he says that after the first heaven, that is, the Empyrean, which he calls most at rest, there was established on day 2 a heaven which is at the extreme limit of mobility, and that this is the Firmament; and in chapter 37 he says that the Firmament made out of the waters is a heaven containing nine heavens. Here he seems to admit eleven heavens, namely the Empyrean, the Firmament or primum mobile, the eighth sphere, that of the Fixed stars, and the seven orbs

of the Planets. He therefore favours us insofar as he does not recognise the heavens of the Planets as the Firmament made out of the waters.

[Margin: St Thomas.] No less — indeed more — St Thomas supports us in his postils on Genesis, saying: *But that Firmament which divides these waters is the heaven itself in which the Fixed Stars are, under which are the seven Planets and their orbs.* He said "under which", not "in which". [Margin: Hamerus.] Hamerus, moreover, reports and tacitly approves the same opinion in his commentary on Genesis, in these words: *There are also those who borrow their understanding from Astronomy. For they interpret this firmament as the eighth sphere, fitted with innumerable torches of stars. By the Greeks it is called Aplane, by the Latins inerratica* [both meaning "the unwandering"]. [Margin: Catherinus.] And clearly Ambrosius Catherinus, in his exposition of chapter 1 of Genesis: *It is therefore far more fitting and more correct that the heaven we call starry, namely the eighth sphere, should be understood by this name.* [Margin: Carthusianus.] And Dionysius Carthusianus too, in his Commentaries on Genesis, article 10: *What is to be understood by the name of Firmament is clear from the fact that a little later the stars are said to be placed in the firmament. Therefore at God's command the firmament was made, that is, the Heaven of the stars, which is the eighth sphere, because under it are the seven spheres, or orbs and heavens, of the planets, etc. And this firmament is now taken as including the seven spheres already mentioned — including them, I say, not in itself but under itself, so that the Firmament solidified out of the waters is the eighth sphere, like a vessel or the shell of an egg containing in itself, or within its own circuit, the heavens of the Planets.* And he adds: *It has already been shown before that the exposition of those is more reasonable, and more consonant with the text and with the ancient and Saintly Doctors, who say that in the beginning the celestial bodies and the elements were produced together under distinct and proper substantial forms. Therefore the Firmament and the Orbs of the Planets were created in the beginning as regards their whole substance, etc.* He therefore distinguishes the Firmament and the eighth sphere from the orbs of the Planets.

[Margin: Hugo Carensis.] The words of Hugo Carensis in his postils say the very same: *The Firmament is the surface of the sensible world, made of waters frozen into Crystal, as they say, containing all the other sensible things after the likeness of an eggshell; and it is called the firmament because it is firm.* [Margin: Comestor.] The Master of the *Historia scholastica* on Genesis, that is, Petrus Comestor, chapter 4, plainly agrees with him: *On that day, namely the second, God therefore made the Firmament in the midst of the waters; that is, a certain outer surface of the world, consolidated out of frozen waters like crystal, and translucent, containing within itself the other sensible things, after the image of the shell that is on an egg; and in it the stars are fixed.*

[Margin: Chrysostom, Procopius, Iunilius.] Moreover, from number 4 of chapter 2 it is established that the heaven of the Planets is not moved but is passed through by the Planets, in the opinion of Chrysostom, Anselm, Procopius, Iunilius, Carthusianus and others; and from number 3 it is established likewise that the highest heaven, which divides the upper waters, is solid. From these,

therefore, it is gathered as the more probable view that the highest heaven is solid, but the Planetary heaven fluid and permeable.

[Margin: 5th argument. The heaven of the Planets the same as Fire, or Aether.] Fifth: according to not a few Doctors, the heaven of the Planets is the same as the Aether, or Fire; but this is without doubt fluid, and yields to bodies moving within it more than air does. [Margin: St Anselm.] The major premise is proved first of all by the authority of St Anselm of Canterbury, adduced a little before and in number 4; [Margin: Iunilius.] and by that of Iunilius in his *Hexaemeron*, who says: *It is to be understood that the birds fly along the firmament of Heaven.* [Margin: Innocent III.] So too Pope Innocent III counts the heaven in the place of the element of fire, saying on the fifth penitential psalm: *In the creation of the World Heaven and Earth were created together, the first and the lowest among the four elements.* [Margin: Bede.] And Bede, in his exposition of Genesis, likewise judged the same when he says: *Since the World consists of four elements, Heaven, Air, Water and Earth.* [Margin: Hugo Carensis.] Almost the same is Hugo Carensis in his postils: *Heaven, that is, the two upper elements; Earth, the two lower.* Nor do Tostatus, on chapter 1 of Genesis, and Rupertus, book 1 of the Commentary on Genesis, chapter 8, refuse it — though as the view of Plato, who understood sacred Genesis in this way; [Margin: Plato.] for they say: *When Plato had read this Scripture, etc. Because he suspected that fire too was signified by "heaven", he thought that only four elements, namely fire, earth, air and water, were enumerated in this place.* [Margin: St Augustine.] To this belongs that saying of St Augustine in the unfinished book *De Genesi ad litteram*: *So that thus four elements have been stated, from which this visible world rises: namely heaven, earth and water, and air*; and in book 2 of *De Genesi ad litteram*, chapter 3: *Therefore above the air pure fire is said to be heaven.*

[Margin: Pliny the Elder.] Well known, too, is the opinion of Pliny the Elder, book 2, chapter 5, who says: *Nor do I see any doubt about the elements, that they are four: the fiery one highest, and from it the eyes of so many shining stars.* [Margin: The Stoics.] Long ago, too, the Stoics called the heaven a moving blaze, [Margin: Heraclitus.] and Heraclitus called it fire; [Margin: Empedocles.] and Empedocles, as quoted by Clement of Alexandria in book 5 of the *Stromata*, enumerated the four parts of the world in these verses:

Earth, and the overflowing Sea, and the moist Air, and Titan Aether, who binds all things round in a sphere.

Anaxagoras and Empedocles asserted that the starry heaven is Fiery, as Plutarch reports in *De placitis* book 2, chapter 13; [Margin: Pythagoras. The Egyptians.] and Pythagoras and the Egyptians held the same, if we believe Albert the Great, *De caelo*, tractate 1, chapter 4. For this reason I judge it neither new nor absurd, but indeed highly probable — [Margin: Delrio. Tellez. Paracelsus.] with Paracelsus, Delrio on chapter 1 of Genesis, and Tellez, disputation 40 of the *Physics*, section 1 — that the aether, or heaven of the Planets, is Fire, and not merely fiery; and that the luminaries are placed in the Firmament in the way in which something would truly and properly be said to be placed

in a room or in a vessel, even if it were not fixed into the roof itself, or into the shell or crust. For the Firmament contains the heavens of the Planets as the shell of an egg contains the white and the yolk, and together with them it makes up one heaven, which in Genesis 1 is called the firmament of heaven. Suarez, Valentia [Gregorio de Valencia] and Pererius ought to grant this all the more willingly, since by the name of Firmament they themselves understand that whole diaphanous body which extends from the earth up to the highest heaven.

CAPVT IV.

Chapter IV.

De Opere diei Quartæ, ideſt de Luminaribus alijſq. Stellis conditis, & in cælo poſitis à Deo.

On the Work of the Fourth Day, that is, on the Luminaries and other Stars created and placed in the heaven by God.

I. We pass over, as if at a leap, the works of the third day — that is, the gathering into the hollows of the earth of the waters that had remained under the heaven, and the plants born from the earth and grown to maturity on that same day by God's command — because they do not bear much on the system of the World, in which the heavens and the celestial bodies are chiefly considered. We therefore move on to the work of the fourth day, which is contained in these words of Genesis: *And God said, Let there be Luminaries in the firmament of heaven, and let them divide the day and the night; and let them be for signs and seasons, and days and years; that they may shine in the firmament of heaven and give light to the earth. And it was so. And God made two great luminaries: the greater luminary to rule the day, and the lesser luminary to rule the night, and the stars; and he set them in the firmament of heaven, to give light upon the earth, and to rule the day and the night, and to divide the light from the darkness.* With these set down, the following questions have to be dealt with.

Quæſtio 1. Cur Siderum Productio in diem quartum dilata?

Question 1. Why was the Production of the Stars postponed to the fourth day?

II. If God had not clothed the earth with grasses and plants on the third day, a physical cause of this postponement could have been given from the dignity of the heaven: for since in six days the whole

business of this work of fashioning was to be completed by divine decree, the first three were assigned to the creation of the great parts and to universal place: namely, the first day to creating the heavens and the elements, the second day to separating the heavens from one another and from the elements, and the third to separating the lower elements. The remaining three days were destined for the adornment of the heavens and of the elements. Therefore the first of these days, namely the fourth from the very beginning of creation, had to be granted to adorning the heaven, as the noblest of bodies and superior among

the simple ones, and to making it illustrious with the most excellent creatures. [Margin: 1st cause of the production of the stars on day 4.] So, setting aside for now the adornments of the plants, this First cause of creating the Sun and the stars on day 4 is put forward by St Augustine, *De Genesi ad litteram* book 2, chapter 13; by Bede with him, in his exposition of Genesis; by Iunilius on the *Hexaemeron*; by the ordinary and interlinear Gloss; and by the Master, on book 2, distinction 14: namely, that the higher and nobler region of the World should be adorned before the lower.

[Margin: 2nd cause.] Closest to this is the Second cause, given by St Thomas, part 1, question 70, article 1; by Hugo Carensis in his postils; by Comestor, chapter 6; by Albert the Great, part 1 of the *Summa*, question 14, article 14; and by Lyranus and Tostatus in their postils: namely, that the heaven had to be adorned first, before the elements, as being more worthy and as already mentioned in first place in the creation of the world. But the same authors teach that plants, as being attached to the earth and immobile, do not belong to that adornment of which Genesis 2 says, *Thus the heavens and the earth were finished, and all their adornment*; whereas the things that have motion do belong to the adornment, because by the very fact that they move from one place to another it is apparent that they are not intrinsic parts of the earth. Sprouts and plants, by contrast, since they are intrinsic to the earth, as hairs are to the skin and flesh of an animal, do not come under the name of the adornment of the earth. Martinengus quotes the words of these Authors in volume 2 of the *Glossa magna*, from page 846 to 848. But some of these same authors, and others, suppose that grasses and plants too belong to the adornment of the earth — for instance Origen, homily 1 on Genesis; Chrysostom, homily 6; and Anastasius Synaita, book 6 of the commentary on Genesis. And certainly that universal particle, *and all their adornment*, that is, of heaven and earth, seems to embrace sprouts and plants as well.

[Margin: 3rd cause.] The Third cause, then, seems to have been that the middle day of this Week, and therefore the nobler, should be adorned with the most excellent things. St Augustine reports this very cause, *De Genesi ad litteram* book 2, chapter 13, but presses against it as if disapproving: for this day was not the middle one among those on which something was produced by God, since on the Sabbath he rested from all work; nor is the Sun more excellent than the animals produced on the fifth and sixth days. And the same can be said against Philo, who thinks that the excellence of the number four was regarded, because four is potentially ten: for if to four you add the preceding numbers, namely 1, 2, 3, ten results.

[Margin: 4th cause.] St Athanasius on Genesis, question 85, and Theodoret in the same place, question 16, pointed to a Fourth cause: namely, that the light of the first three days, being excessive and intolerable to animals, should be tempered and diminished by being distributed among several stars — as though the whole heaven had previously shone in the way the Sun now does, or as though it were certain that that light was then more intense than afterwards.

[Margin: 5th cause.] The Fifth cause, according to Procopius on Genesis chapter 1 and others cited in Martinengus, page 845, is said to have been that lamps should be lit for the banquet being prepared for man, and that the less noble things should be sent ahead of man, as attendants and forerunners go before an emperor.

[Margin: 6th cause.] But to me the most probable of all seems the Sixth cause. On the one hand, it was to be clear that light — which is the universal vehicle of influences and the soul of colours — and the grasses and plants, which seem to depend most of all on the heaven, do not depend essentially on the Sun and the other stars; and men would therefore be turned away from idolatry and from offering worship to creatures that are otherwise most beautiful. On the other hand, the stars were to exercise from the beginning, together with God the principal founder, some power in producing animals, and were not to seem inferior to the elements. Nor ought their production to be deferred to the last day, lest God should seem to have come to rest in it as the most excellent work and the end of the others. [Margin: Philo.] The first part of this cause was indeed handed down by Philo in his book *On the Creation of the World*, whose words very well deserve to be copied here. This, then, is how he speaks of God the craftsman: *For he foresaw the opinions of men not yet created: that they would follow probable conjectures, which have much appearance of reason, but not likewise pure truth; that they would believe their own eyes more than God, admirers of sophistry rather than of wisdom; and that they would credit to the courses of the Sun and Moon — to the summer, winter, spring and autumn changes — and to the circuits of the heavenly stars the causes of the yearly produce of the earth and of all things that spring up. Lest they should dare to ascribe the first causes to any creature, whether through impudence or through ignorance, let them go back in their minds* (he says) *to the first generation of this universe, and remember that before the Sun and the Moon plants of every kind and fruits of every kind came forth from the earth. And so let them persuade themselves that hereafter too the earth will bring them forth by the will of the heavenly Father, whenever it pleases him, without waiting for the favour of the heaven, to which he gave power indeed, but not free power, etc. And this is the reason why the earth sprouted first and brought forth grass.*

[Margin: St Basil.] St Basil, having pursued the very same point at length and eloquently in homily 5 of the *Hexaemeron*, condenses it in homily 6 into these few words: *Heaven and earth came first; light was created after heaven and earth; night and day were separated; then the firmament was brought forth; next the dry land emerged, and the waters flowed together into one determined place. At last the earth was filled with its sprouts, both with innumerable kinds of grasses brought forth and abounding with various forms of shrubs and trees that sprang up in a moment. But there was not yet a Sun, nor a Moon — lest those who do not know God should call the Sun the prince and father of light, or judge it to be the creator of the things that spring from the earth. That is why the fourth day came: and then God said, Let there be Luminaries.*

[Margin: St Ambrose.] But sweeter than all honey, and even than ambrosia, are the words of St Ambrose on this matter, *Hexaemeron* book 4, chapter 1: *Beware therefore,* he says, *lest the rising ray of the Sun confound your sight too. And so look first at the firmament of heaven, which was made before the Sun; look at the earth, which began to be visible and composed before the Sun came forth; look at its sprouts, earlier than the light of the Sun. The bramble is earlier than the Sun; the grass older than the Moon. Do not, then, believe that to be God before which you see God's gifts were preferred. Three days passed, and no one looked for the Sun, and the brightness of light abounded.* And a little later: *What, then, did the height of the wisdom and knowledge of God foresee, that trees should begin to exist before those two luminaries of the world, and certain heavenly eyes of the firmament, unless that all should know, by the testimony of the divine reading, that the earth can be fruitful without the Sun?*

[Margin: St Chrysostom.] Let that golden mouth, namely Chrysostom, homily 6 on Genesis, join this ambrosial mouth. He teaches that the grasses were sent ahead of the Sun, *so that you may not ascribe the produce of fruits to the Sun, but to God, the maker of all, who said from the beginning, Let it sprout*; and below: *What we have said of the seeds may also be said of the day: that there were three days before the formation of the Sun*, etc. [Margin: Severianus.] Severianus, in Lippomanus's *Catena*, offers things similar to these: *Why did God adorn the earth before the heaven? Because of the error that was to come about many Gods, such as the Sun, the Moon and the Stars.* [Margin: Procopius.] And Procopius, in the Commentaries on Genesis, chapter 1: *The Sun followed the plants, grasses and sprouts in the order of creation, lest anyone should believe it to be the author of the things just mentioned. So too the creation of light long preceded it, lest anyone should perhaps tacitly judge the Sun to be the bestower of light, and divine worship be decreed to it on that account. For what reason allows the Sun to be the origin of light, when the creation of light preceded it?*

Quæſtio 2. Fueritne Sol cum reliquis ſtellis quarta die productus quoad ſubſtantiam; An illis prima die productis indita ſit lux tanquam forma, & addita vis influendi, ac motus proprius diſtributus?

Question 2. Was the Sun, with the other stars, produced on the fourth day as regards its substance? Or, the stars having been produced on the first day, was light put into them as a form, and a power of influencing added, and a proper motion distributed?

III. You see the whole variety of opinions on this matter indicated in the title of the question. [Margin: 1st opinion and its authors.] For the First opinion was that the Sun and the stars were created on the first day, together with the heaven, as regards their substance; but that on the fourth day light was gathered and poured into the Sun and the stars, a determinate power of influencing added, and finally a motion proper to each star assigned toward the East, so that they might be signs of the seasons, etc. So taught St Thomas, on book 2 [of the *Sentences*], distinction 13, and part 1, question 67, article 4, and question 70, article 1, reply to 1; Dionysius Carthusianus on Genesis, articles 9 and 12;

Aegidius, part 2 of the *Hexaemeron*, chapters 5, 6 and 31; Catherinus on chapter 1 of Genesis; Vielmius in the same place, lecture 20; Augustinus Eugubinus in the *Cosmopoeia*; Valentia, disputation 5, question 3, points 1 and 4; Pererius, book 1 on

Genesis, page 49; Suarez, *De opere sex dierum* book 2, chapter 8, from number 16, and chapter 9; Tannerus, volume 1 of the *Theology*, disputation 6, question 4, doubt 2. Among these, Catherinus and Vielmius think that the Sun was produced on the first day and perfected on day 4 accidentally, with light, power and motion; but that the Moon and the other stars were produced on day 4 as regards their substance — for they cannot understand the primeval light as anything other than the Sun. Eugubinus, however, by a plainly arbitrary fiction, affirms that the Sun was founded on the first day, the Moon on the second, the other Planets on the third, and the Fixed stars on the fourth. Pererius, moreover, says that light was given to the Sun as an essential form — a view supported by St Nazianzen, oration 43, and supported also by the Hebrew name of the Luminaries, Meoroth, and by the Greek of the Seventy, φωστήρες [phōstēres, "luminaries"]; he also mentions a determinate power for influences, and a proper motion. Suarez, on the other hand, teaches that the Sun and all the stars were produced on the first day as regards substance, light and power of influencing, and that on day 4 they received nothing other than their proper motion; Tannerus, a more intense and stable light, and their proper motion. The foundation of these views — though not of all of them — is twofold: first, that the heavens are incapable of new generation, of condensation or rarefaction, and that therefore all the celestial bodies had to be created on the first day; and second, that they think it very difficult to explain what kind of light that was which was made on the first day, and how the first three days consisted of morning and evening, unless it is said that the Sun and the Stars existed as regards substance, and as regards motion — but the common motion, that is, that of the primum mobile.

IV. [Margin: The 1st opinion attacked.] But the opinion already mentioned must without doubt be rejected by anyone who wishes, as he ought, to understand Sacred Scripture literally, since in this there is no conflict — indeed, as will be said later, there is the greatest agreement and an admirable order of the divine works. Next, the opinion already mentioned has none of the ancient Fathers as its patrons, and most of them against it. Moreover, the authority of Sacred Scripture by itself, and much more with the interpretation of the Fathers joined to it, ought to have moved the mind of every prudent man to understand that the Luminaries and stars were made anew on day 4, at least as regards form and shape; to resolve those very slight difficulties that had presented themselves in the production of light on the first day outside its proper subject, and in the production of the Sun on day 4; and not to measure their production by merely Physical rules, but by the divine power made manifest to us by God himself in such clear words. For in what clearer and simpler words, I ask, could Moses have explained to us the new production of the Luminaries and stars, and their

placing in the heaven, and then the distribution of their charge and office, than in those he used? [Margin: 1st and 2nd argument.] And let this be the First Argument, namely the authority of Sacred Scripture understood literally; for the Second, from the Fathers, will be adduced shortly, to confirm the second opinion.

[Margin: 3rd argument.] The Third argument is that Sacred Scripture said not only that the Luminaries were made on that day, but that they were placed in the heaven and ordered to divide the night and the day, and to be for Signs and seasons, etc. Now if they were made on the first day, where were they placed? Or if they were placed in the heaven on the first day, why is this passed over in silence on that day and ascribed to day 4? Does this not give occasion for manifest error to the uneducated people for whom, they hold, Moses wrote above all? Besides, if the first day had the motion of the primum mobile, and the day was divided from the night by it, why is that office repeated, or insisted upon, on the fourth day? For these words, *and let them divide the day and the night*, contain not the proper motion toward the East but rather the common motion.

[Margin: 4th argument.] Fourth: the proper motion of the planets and of the Fixed stars toward the East is very remote from the common notion of ordinary people — indeed the proper motion of the Fixed stars was detected only by Hipparchus — nor is it in itself an accident worthy of God's assigning a whole day to arranging it alone, if one considers the works of the other days, on which either great bodies of the world were founded or separated, or substances of different kinds were produced with their accidents, and not merely a motion, or one accident or another. So on days 5 and 6 animals were produced, and not merely their manifold motions.

[Margin: 5th argument.] Fifth: the end would be lost which, in the opinion of the most weighty Fathers and Doctors, God had in deferring the production of the Luminaries and stars until day 4 — namely, that it might be apparent that the Light of the heaven, and the plants of the earth, could exist and be brought forth without the Sun and the stars, and that in this way men might be turned away from offering divine worship to the Sun, the Moon and the host of heaven; we have already spoken of this end in the preceding question. I therefore cannot let pass unreproved, above all, Steuchus, or Eugubinus, who wishes to attribute to the Sun what neither Scripture nor the Fathers attribute to it. For he says in the *Cosmopoeia*: *The Sun, gathered into a globe and kindled, itself did the remaining works on earth. Once made, it made the day, made the air, made the uncovering of the earth, drained the waters, created the plants and the animals.* Is this deterring men from adoring the Sun? But how gratuitously, and out of his own free invention rather than from the light of the divine writings, he imagines that the Sun was founded on the first day, the Moon on the 2nd, the lesser Planets on the 3rd, and the stars on the 4th! In this he errs more than Catherinus and Vielmius, who grant that the Moon and all the Stars, the Sun excepted, were founded on the fourth day.

But that all the Luminaries were produced by God on the same day, as things of the same order, is taught by [Margin: St Athanasius.] St Athanasius, sermon 3 against the Arians: *For all things alike obtained their rise and origin together with all; although among themselves some differ from others in glory. For not one of the stars, or of the great luminaries, so appeared that this one emerged into the nature of things earlier and that one later; but all were called into being on the same day and by the same command*, etc. [Margin: Theodoret.] In a similar way Theodoret, expounding that verse of Psalm 71, "His name endures before the Sun", discourses thus: *This particle, Before, declares him to be older than the Sun and the Moon. For it is not simply that he endures before the Sun; rather, he placed the generation of generations before the Sun and the Moon. For the Sun and the Moon are of the same time: they were made at the same time. For God said, Let there be Luminaries in the firmament of heaven; and God made two great Luminaries.*

V. [Margin: 2nd opinion.] The Second view, then, and one wholly certain in my judgement, is that on the fourth day God made the Luminaries and the Stars anew — whether by producing them out of some matter (for we have already taught, in chapter 1, number 7, that whatever was created out of nothing and by creation strictly taken, he created on the first day), or by a condensation of parts of the heaven, as some would have it. For even if the second way does not include the production of a new substance, and no generation physically taken occurs through it, nevertheless, regarding God here as the supreme craftsman, a certain new artefact is posited as made, which is like a substantial production — so much so that Aristotle brought forward the forming of a statue as an example of substantial generation, because something is said to be made a being simply, and not made such-and-such with some accidental addition. For this reason we shall also adduce for this view those Authors who think that the stars were made by mere condensation and configuration of parts of the heaven. This is the opinion of Ascanius Martinengus in the *Glossa magna*, page 867, who calls it a quasi-ecumenical definition; of Molina, *De opere sex dierum*, disputation 15; and of Salianus in the *Annales Ecclesiastici* of the Old Testament, at the 4th day of the World.

[Margin: 1st proof, from the Scriptures.] And it is proved, First, from Sacred Scripture taken in its plain and literal sense. By the words *Let there be* and *He made*, Scripture signifies the production of the Luminaries and stars by God on this fourth day in the same way as on the first day it had signified the production of Light; it then expresses the place in which they were produced and placed, and finally recalls the offices of the stars. And it can be understood of a new production as regards substance without any conflict or difficulty. Indeed, this view not only makes the sequence of the text clear and separates the works of this day clearly and distinctly from the works of the other days, but also displays a most fitting disposition of divine providence. For what is more fitting than that God should found no mixed or particular body before he had fashioned the universal and greater bodies and had divided and separated them perpetually by fixed limits and regions — which was done in the first three days, as is clear from

what has been said so far; that he should then, beginning from the vegetative grade, produce plants and grasses; then step up to the things that require a power of moving from place to place, whether intrinsic or extrinsic, of which kind are the stars; afterwards, proceeding to the sensitive grade, produce on the fifth day the animals of the water and the air, which are the ornaments of the two elements nearer to the heaven and are moved by the rowing of wings or fins; and finally, on the sixth day, make the earth inhabited, first by brute animals and then by rational ones?

Secondly, it is proved by Authority: for rightly Martinengus says: [Margin: 2nd proof, from the Fathers.] *This opinion has stronger supporters, superior both in number and in authority. It is better fortified by antiquity, since it had taken root in the Church, received by the common votes of the Fathers, almost twelve hundred years before the others.* And above all the Church assents to it in the hymn:

> *Who on the fourth day, setting up the flaming wheel of the Sun, the ministering order of the Moon, and the wandering courses of the stars.*

[Margin: Tertullian.] We also have that poem of Tertullian:

> *The fourth day begets the Moon together with the lamp of the Sun, and fashions the stars, radiant with trembling light.*

[Margin: St Basil.] St Basil, homily 6 on the *Hexaemeron*: *For then, that is, on the first day, the very nature of light was produced; but now this body of the Sun was founded for this purpose, that it might be a vehicle for that firstborn light.* [Margin: St Ambrose.] St Ambrose, who almost always supports him, in book 4 of the *Hexaemeron*, chapter 1, where he begins his explanation of the works of day 4, says: *In our reading the Sun must now rise, which had not existed before. We have already passed the first day without the Sun; we spent the second without the Sun; we completed the third without the Sun. On the 4th day God commands the Luminaries to be made: the Sun, the Moon and the Stars.* [Margin: St Chrysostom.] So too St Chrysostom, homily 6 on Genesis: after the earth had been adorned with grasses on the third day, he teaches that the heaven was adorned on the fourth day, *above all by the formation of the two great luminaries, the Sun, I say, and the Moon*; and he adds: *For this reason he made the Sun too on the fourth day, lest you should think it the author of the day.* [Margin: Severianus.] Severianus, most briefly: *After the earth had sprouted, then God made the Sun and the Moon.* [Margin: Procopius.] In no other sense Procopius, chapter 1 on Genesis: *First light was brought forth into the open; then at last the receptacle of light was founded*; and he compares the Sun to a lamp, and the light to fire, etc. I have put these five Fathers first because they are the same who teach, with Philo, that the production of the Sun was deferred to the fourth day for this reason: lest the Sun be thought the first author of light and of plants, as we showed in question 1 of this chapter.

[Margin: St Nazianzen.] St Gregory Nazianzen, in the oration on New Sunday, says that the first light was founded by God *not through some instrument, or the Sun, but incorporeally and without the Sun*; and a little later: *But, in order*

to make something worthy of greater admiration, here he placed the form before the matter: for the form of the Sun is light. Then he also brought in the matter, founding this Sun as the eye of the day. So he made the body of the Sun on this day — granted that he made its form, if its form is light (as Nazianzen and our Pererius think), on the first day, at least as regards its species.

[Margin: St Augustine.] St Augustine, book 1 *On Genesis against the Manichees*, chapter 14, answers those who ask how the stars — that is, the Sun, the Moon and the stars — were made on the fourth day, and how the three earlier days could have existed without the Sun, in this way: *To them we reply that it could have come about that the three former days were each reckoned by as long a span of time as the Sun takes to go round, from the moment it proceeds from the East until it returns again to the East. For men could perceive this span and length of time even if they lived in caves, where they could not see the Sun rising and setting. And so it is understood that this span could have taken place even without the Sun, before the Sun had been made.* How much more readily he would have answered the Manichees, had he thought that the Sun was made as regards its substance on the first day and had the motion of the primum mobile! Eucherius, as usual, subscribes to him, book 1 on Genesis, chapter 5.

But since the matter is clear, and undoubted among the ancient Fathers, I have no need to review them one by one. If anyone wants their words, let him read them at their sources, or in Martinengus, *Glossa magna*, from page 859 to 873, or in Salianus at the 4th day of the world; let it suffice to have indicated the places. The following, then, may be seen: St Damascene, book 2 *On the Faith*, chapter 7, who calls a Luminary the receptacle of Light; St Athanasius, question 74; St Nyssenus [Gregory of Nyssa], the book *On the History of the Six Days*; Theodoret, question 14 on Genesis, and on Psalm 148; Anastasius Synaita, book 4 on Genesis; Apollinaris, in Steuchus; Didymus, in Lippomanus's *Catena*; St Bonaventure, on book 2, distinction 14, where, on St Basil's opinion of the Sun as a vehicle and vessel of light made on this day, he adduces that verse of Ecclesiasticus 46: *An admirable vessel, the work of the most High*; Burgensis, in the *Additions*; Hugo Victorinus, in the notes on Genesis, chapter 6, and book 1 *On the Sacraments*, part 1, chapter 15; the Master, on book 2, distinction 13; Comestor, chapter 6 of the *Historia Scholastica*; Lyranus in the *Postills*, who chooses this view; Tostatus on Genesis; and almost all the others before the 13th century.

Quæſtio 3. Quo modo Producta ſint Luminaria & ſtellæ quarto die? Num Creatione ex nihilo, an Condenſatione & Rarefactione; An generatione per productionem formæ ſubſtantialis?

Question 3. How were the Luminaries and stars produced on the fourth day? By creation out of nothing, or by condensation and rarefaction? Or by generation, through the production of a substantial form?

VI. [Margin: 1st opinion: that the stars were created out of nothing.] The First opinion was that of Burgensis in the *Additions* on Genesis. He held that

the primeval light was miraculous and produced in a supernatural way; and, once natural provision had then been made, he says that the Luminaries and stars were created out of nothing on the fourth day, because God said *Let there be luminaries*, etc., just as he had said *Let there be light*. He did not say *Let the heavens bring forth luminaries*, or *Let a bright cloud bring forth the Sun*, as he said *Let the waters bring forth*, *Let the earth sprout*, etc. — and this, to show us that no subject concurred in their production. On that day, moreover, the firstborn light was wholly extinguished: just as Joshua 5 says, *The manna ceased after they had eaten of the fruits of the land*, so that extraordinary light ceased when the stars, the sources of ordinary light, were created. Suarez, book 2 of *De opere sex dierum*, chapter 8, number 2, would have subscribed to this opinion had he thought that the Sun, etc., was produced on day 4 as regards its substance; for, he says, *since the luminaries and stars are incorruptible bodies, they cannot, in keeping with their nature, be produced except by creation out of nothing.* Yet he says that this opinion has no weighty supporters — for he mentions none — and that it is to be rejected, because whatever God produced by creation properly so called, he created at once and all together from the beginning, as is the accepted view of the Theologians and as we have already taught in chapter 2, number 7. It does not follow, however, that if the Stars are incorruptible intrinsically, they require to be created out of nothing. For they can consist of matter and of a form such that the matter is wholly filled and seeks no other form, and that there is no natural agent able to introduce contrary dispositions and to assail them with that corruptive alteration; and so they can be incorruptible of themselves and yet be produced out of such pre-existing matter. I add, moreover, against Burgensis: by the very fact that Moses did not say *he created*, but that God said *Let there be*, God surely commanded some creature to concur in that production, at least in the order of a material and sustaining cause; and so he also drew the first light out of the potency of the diaphanous body, and did not create it out of nothing, as Burgensis supposes. But to the earth and the waters he said *Let it sprout*, *Let them bring forth*, etc., because he willed that they should concur in the production of those mixed bodies not only as a material and sustaining cause, but also as an instrumental efficient cause — through the remote dispositions of the primary qualities, which they already had, and the proximate dispositions of the secondary qualities, or of the temperament proper to each of the mixed bodies, which he put into them.

VII. [Margin: 2nd opinion: of condensation and rarefaction.] The Second opinion is that the Sun and the other stars were made from the same matter of which the starry heaven consists, but by mere condensation or rarefaction. This opinion is mentioned by Molina, *De opere sex dierum*, disputation 15, and by Suarez, book 2, chapter 8, number 5, with no Author named; and they suppose it follows from this opinion that the Luminaries and stars do not differ substantially among themselves or from their heaven, but only in quantity of matter, which makes density, or in scarcity of it, which makes rarity. All those, however, who said that the Sun and the stars were made from that primeval

light, gathered into these bodies, or globes of the stars, and distributed into them, might seem reducible to this opinion — for I do not believe that they took the light to be an accident alone, without a subject. Among them were Gregory of Nyssa, Didymus, Apollinaris, Athanasius, Aegidius, Albert the Great and some others, named at the end of number 5. Singular among them is Nyssenus in the *History of the Six Days*. He says that the stars were made from a collection and heaping together of light, or fire — yet in such a way that its parts were already, beforehand, some denser than others and of different natures — and that on the 4th day all the particles that were of the same nature, say solar, flowed together to constitute the Sun, and those that were lunar to the Moon, and so on for the rest. Furthermore, Albert the Great, part 1, question 4, article 21, and St Bonaventure, on book 2, distinction 14, but from

the mind of Aristotle, teach that the stars were made from a condensation of the heaven. Finally Aegidius, in the *Hexaemeron*, part 2, chapter 31, imagines a threefold condensation of light: the first unfit for illuminating; the second fit for it, when light is said to have been made dividing the day from the darkness; the third when it was condensed into the body of the Sun. But since that light was diffused through all diaphanous bodies — that is, through the whole extent of the heavens and of the waters above the earth — if it had been gathered by condensation, together with its subject, into the stars, then the whole matter, at least the celestial matter, would have passed into the stars, and it would have been necessary to produce the starry heaven anew, at least by rarefaction, so that the void might be filled. This has no appearance of probability, nor does it agree with Scripture, which supposes that the stars were placed in a firmament and heaven already made — in fact, on the first and second day. Suarez, however, refutes this opinion on other grounds. He thinks that the celestial bodies are incorruptible, and indeed that in their first production they must have been optimally disposed and must connaturally have required the whole perfection of their substance, and so their due density and rarity; whereas condensation and rarefaction befit only corruptible bodies, since such changes are by their nature ordered to corruption and generation. But he proves this with no valid arguments, and he seems not to recognise any natural condensation and rarefaction other than that which comes about by the force of heat and cold. Besides, the things that the Author of nature made in the beginning are not to be judged by the same law as those that are now made by other natural agents.

So for my part this opinion does not satisfy me, on a different, twofold ground. First, because the perfection of the Sun, the Moon and the Stars — that is, of bodies so noble, and of so great and so varied a power for influencing such varied sublunary mixed bodies — certainly seems to require that at least the Planets have a substantial form differing among themselves and from the heaven, one that virtually contains the lower mixed bodies; and even if the whole heaven of the Sun were condensed into one globe, one Sun would never be forged out of it. Secondly, because if any of us had been present at the

production of the stars on the fourth day, he would have had all those signs of a new substance produced that we have now when we see some substantial composite produced — namely a new shape, colour, light and active powers — and these moreover persisting together, with such constancy, up to this very day. Therefore Scripture is to be understood in a plain and simple sense, of stars made simply, that is, produced as regards their substance. Otherwise we could refer most of the things that are made anew to condensation and rarefaction.

VIII. [Margin: 3rd opinion: of substantial generation.] The Third, then, and true opinion is that the Sun and the other Stars were produced on the fourth day as regards their substance — not from nothing, but from some matter, of which shortly — in such a way that they received a proper and distinct substantial and specific form. This was the view of those who hold that the Luminaries and stars were produced from air, or from a bright cloud, or from water, or from fire, of whom we must speak in the following question. This mode of production is defended by Molina, *De opere sex dierum*, disputation 15; by Salianus at the 4th day of the world; and, before them, by Hugo Victorinus, chapter 6 on Genesis and book 1 *On the Sacraments*, part 1, chapter 15 — for he says that the form of the Sun was made from a bright cloud or from fire, as wine was made from water at the wedding at Cana; by Lyranus in the *Postills*, in the second exposition, who says: *Here the work of the fourth day is described; and it is understood that the Luminaries are made here as regards their specific substantial forms*; and by Tostatus, or Abulensis, on Genesis, who says: *Hence it is believed that the Sun was made from that little cloud, advanced substantially into another species, and accidentally in brightness and in the power of influencing.* It remains for us to investigate, from the Fathers and Doctors of the Church, from what matter the Luminaries and stars were produced on the fourth day.

Quæſtio 4. Ex qua Materia facta ſint ſeu producta quarto die Mundi, Luminaria & ſtellæ, Ex quintane eſſentia An ex materia Elementari?

Question 4. From what Matter were the Luminaries and stars made, or produced, on the fourth day of the World: from the fifth essence, or from elemental matter?

IX. [Margin: 1st opinion: of the matter of the simple heaven.] The First opinion was that all the Stars and Luminaries were made from the celestial body itself, or from the matter of the heavens condensed and intensified — but in such a way that the celestial body is simple, and not composed of any elements. So thinks Albert the Great, in the first part of the *Summa de quatuor coaevis*, question 4, article 21. [Margin: The opinion of Albert the Great and St Bonaventure.] This was the opinion of Aristotle and of almost all the Peripatetics, and so St Bonaventure, on book 2, distinction 14, in the Commentaries, said from that opinion: *It can be said according to the Philosopher that the luminaries were produced from an aggregation of light, or of their orbs. For just as scattered heat, if it were gathered into one, would become more intense and stronger, so, when the nature of light found in the orbs is gathered into one by the power of its own fashioning, a luminary is constituted; and accordingly a luminary is greater or lesser according as*

the aggregation of light in it is greater. The Peripatetics may be seen on book 2 of *De caelo*, chapter 7, or from text 41.

X. [Margin: 2nd opinion: the stars from earthy matter.] The Second opinion was that the Sun and the stars are clods of earth, or stones, snatched up and set alight by the whirling of the heaven. So Theodoret, in the book *On Matter and the World*, and Plutarch, book 2 *On the Opinions of the Philosophers*, chapter 13: [Margin: Thales.] *Thales said that the stars are earthy, but fiery.* [Margin: Anaxagoras.] *Anaxagoras said that the surrounding aether is fiery in its own essence, but that, snatching up rocks from the earth by the force of its whirling, it set them alight into stars with its own fire.* [Margin: Diogenes.] *Diogenes thinks the stars are like pumice, and are the breathing-holes of the world; and he also holds that invisible stones often fall from heaven and are extinguished — just as once a stony star, very like fire, fell at the river Aegos.* But Theodoret adds that Anaxagoras, accused by Cleon of having said that the Sun is a glowing plate, was condemned by the Athenians as one of the atheists. Diogenes Laërtius reports similar things here and there in the lives of the philosophers already mentioned. Further, in the same Theodoret and in Plutarch, book 2 of the *Placita*, chapter 20: *Anaxagoras, Democritus and Metrodorus said that the Sun is a globe of glowing iron, or a fiery rock; and Epicurus, an earthy compaction, like pumice, fiery within its eaten-out passages.* [Margin: Euripides.] So Euripides, the disciple of Anaxagoras, in the tragedy *Phaethon*, called the Sun a golden clod. It is of these authors, I believe, that Seneca speaks in book 7 of the *Natural Questions*, chapter 1. For when he had said, *No one could inquire into anything more magnificent, or learn anything more useful, than the nature of the stars and constellations — whether it is contracted flame, as our sight too affirms, and as the very light flowing from them and the heat coming down from there affirm*, he went on: *Or whether they are not fiery orbs, but certain solid and earthy bodies which, gliding through fiery tracts, draw their splendour and heat from there, bright not of their own; in which opinion there have been great men, who believed that the stars are compacted from something hard and feed on a fire not their own.* [Margin: Philo's censure of this opinion.] Philo, however, sharply rebukes them and condemns authors of this kind to eternal fires, in the book *On Dreams*. For he says: *What are the stars themselves? Are they fiery masses of earth? For some say they are fiery hills and glades. They themselves deserve the mill and the prison, where these instruments exist for torturing the impious who are like them.* These, then, we pass over — above all because they have no Fathers or Doctors of the Church as their patrons.

XI. [Margin: 3rd opinion: the stars from water, or air, or vapours.] The Third opinion was that the Sun and the stars are of the matter of exhalations and vapours, and hence partly watery, partly airy. The Stoics held that the stars are fiery and feed on vapours. [Margin: Pliny.] So Pliny, book 2, chapter 9, especially about the Moon; for he says: *The stars undoubtedly feed on earthly moisture, and the Spots of the Moon are nothing other than the dregs of the earth, snatched up with the moisture. For things consist of those things by which they are*

nourished. [Margin: Xenophanes.] And in Plutarch, book 2 of *De placitis*, chapter 13: *Xenophanes [held] that the stars are compacted from fiery clouds, extinguished by day, and at night glow again like coals; and that their risings and settings are kindlings and extinctions.* [Margin: Zeno.] Zeno Citticus [Zeno of Citium], in Laërtius, book 7, said that the Sun draws from the sea the nourishment of intelligible — that is, most subtle — fire. But, to consult the sacred authors: [Margin: Comestor.] Petrus Comestor, chapter 6 of the *Historia Scholastica*, says: *Of that bright cloud it is handed down either that it returned into the matter from which it had been made — like the star that appeared to the Magi, and the dove in which the Holy Spirit was seen — or that it always accompanies the Sun, or that the solar body was made from it.* [Margin: Tostatus.] Similarly Tostatus on Genesis: *Hence it is believed that the Sun was made from that cloud*, etc. [Margin: Hugo Victorinus.] Further, Hugo Victorinus, in the notes on Genesis, chapter 6, says: *But all the Stars, like the Moon too, were made of airy matter, and only reflect light; they do not shine — that is, they do not shine by their own light, but by light received from the Sun, which is held to have been made from light, or from a bright cloud.* [Margin: Eugubinus.] But more safely Steuchus, in the *Cosmopoeia*, saying: *This is most true, and asserted also by the most ancient Theologians, that in the same way there was drawn out of the waters the ethe-*

real substance, and the heaven itself, and the heavenly breathings. For we see water changed into air, into clouds, into torches and fiery vapours. It must therefore be thought that this was done at that same time, when the wisdom and genius of God was borne over the waters and drew purer substances out of them — first the Sun, whose elaborate size and beauty surpass all things celestial and terrestrial. Stirring, then, and shaking the waters he had created, he separated them, and kindled fire, and the purest lights, as of mirrors and of clouds, etc.; and he adds: *Flame is nothing other than kindled air.*

XII. [Margin: 4th opinion: that the stars are fiery.] The Fourth opinion, and the most celebrated, was that the Sun and all the other stars are fiery and produced from fire, or consist of a fiery form. Among more recent writers it has been embraced by Ascanius Martinengus in the *Glossa magna*, page 875; Steuchus in the *Cosmopoeia*; Salianus in the *Annales Ecclesiastici*, at the 4th day of the World, from number 4; and Christoph Scheiner in his *Rosa Ursina*, book 4, part 2, chapter 17; Boulliau, book 1 of the *Astronomia*, chapter 7; Franciscus Resta, tractate and book 1 of the *Meteorologica*, chapter 10; Tellez, disputation 44 of the *Physics*, section 3, number 14 — although he thinks here that certain stars consist of other elements. [Margin: Empedocles, Zeno, Cicero, Trismegistus, Hermes, Xenarchus, Plato.] So, long ago, Empedocles declared the stars to be fiery and to consist of fire, as Plutarch relates, book 2 of *De Placitis*, chapter 13; and so did Zeno with the Stoics, whom Cicero joined on this point, book 2 of *De natura Deorum* and the book *On the Dream of Scipio*. Trismegistus held the same in the *Pimander*, chapter 10; Hermes, in Cyril, book 2 *Against Julian*; Xenarchus, in Simplicius, book 1 on *De caelo*; Seneca, book 7 of the *Natural Questions*; Germanicus, the interpreter of Aratus, who says: *The Sun meanwhile,*

while it is fiery, grows hotter still because of the excessive motion of its revolution; and the Philosophers say that its fire is nourished by water; and Manilius, book 1, from the verse *It marks out fiery forms, and fires answer to fires*, etc. Plato too held them to be fiery for the most part, but sharing also in the other elements, after the manner of a glue. Granted that Aristotle argues against him in book 2 of *De caelo*, chapter 7.

Sacred Scripture certainly favours this opinion when, in Ecclesiasticus 43, the Sun is likened to a furnace of burning: *The Sun when it appears, announcing at its going forth, an admirable vessel, the work of the most High. At noon it burns up the earth, and who shall be able to endure the face of its heat? Keeping a furnace in works of heat; the Sun three times as much, burning up the mountains, breathing out fiery rays, and shining with its rays it blinds the eyes.* Taken literally, these words signify that the Sun is a kind of furnace of heat, and so hot formally. So too the Church, in the Vespers hymn for the 4th feria:

> *Who on the fourth day, while you kindle the flaming wheel of the Sun*
> —

unless you think this said poetically. So Juvencus sang in the prologue of the first book of the *Evangelical History*:

> *Nothing is held immortal in the frame of the World, not the sea, not the land, not the fiery stars of heaven.*

And in book 3 he calls the Sun *Ignicomus*, "fire-haired"; and Proba Falconia, in the *Centos*:

> *For there were not yet the fires of the stars, nor the bright aether.*

And Dracontius, book 1, *Hexaemeron*:

> *Soon he bids the globe of the Sun shine with the fire of salvation, and bids the Moon go second from its fire.*

But the Fathers certainly seem to have spoken not poetically but properly. [Margin: Philo.] The most ancient of them, Philo, in the book *On Dreams*: *There are certainly some who say that the Moon is not a globe of pure aether, as the other stars are, but mixed of aether and air; and that the spot appearing in it, which some call a face, is nothing other than the admixed air, which by its own nature is believed to be black all the way up to the heaven.* [Margin: St Justin.] St Justin, in the book on the refutation of the doctrines of Aristotle, teaches that the Sun cannot heat unless it is itself hot. [Margin: Tertullian.] Tertullian, in the book *On the Soul*, teaches that the Sun is endured by the eyes of the eagle, while it is invisible to owls — *not because it is incorporeal, but because the visual power fails*; and he adds: *For the Sun is a body, since it is fire; but what the eagle would confess, the owl would deny.* [Margin: St Basil.] As for those who deny that the Sun is hot, see with what a brand St Basil marks them, homily 3 on the *Hexaemeron*: *Although*, he says, *they do not even grant that the Sun is hot: such abundance of time overflows for them for ravings and old wives' trifles*, etc. [Margin: St Ambrose.] St Ambrose, following him closely, book 2 of the *Hexaemeron*, chapter 3: *We often see the Sun moist and dewy, by which it gives evident sign that it has taken to itself a nourishment of waters for its own tempering. But there is in them such zeal*

for attacking the truth that they deny the Sun itself to be of a hot nature, etc. And he goes on to say that the Sun is therefore now in one place, now in another, lest, if it rested in one place, it should burn up everything there.

[Margin: St Cyril of Jerusalem.] St Cyril of Jerusalem joins these, catechesis 9: *The heaven is water, and in it the Sun is fiery, and the Moon and the stars; and how do fiery things run in water? But if anyone doubts this because of the contrary natures, let him remember that fire in Egypt, in the time of Moses, burning in the hail, and consider the most wise workmanship of God.* [Margin: St Cyril of Alexandria. Hermes.] The other Cyril too, that is, of Alexandria, book 2 *Against Julian*, on the opinion of Hermes, has this: *Hermes, in the books of the Diexodica, in the first discourse, said: The Lord of all said, by his holy and intellectual Word, which has the power of founding: Let there be a Sun; and at once fire appeared, which by nature is borne upward — pure, I say, and most brilliant, and most fertile.* [Margin: St Nyssenus.] Most clearly of all, St Gregory of Nyssa, in the *History of the Six Days*, teaches that the light made at the first was fire, separated from the mass of the other elements, but having diverse qualities: one for constituting the Sun, another the Moon, another the other stars. [Margin: Caesarius.] Add to these Caesarius, who says expressly, in questions 68 and 69, that the Firmament is crystal, which was to receive the Sun and the Moon and the company of the other stars, *which has its nature from fire*; so, lest what is fixed should be dissolved by their heat, by means of it he separated that boundless water from it, placed as it were upon its shoulders to cool the inflammation. [Margin: St Chrysostom.] No less absolutely St John Chrysostom, in the homily to the Neophytes: *The nature of those stars is fiery, and these are taught to obtain a fiery nature*; and in homily 6 on Genesis he calls the Sun the element of fire: *For the Sun not only heats, but also dries; and not only dries, but also scorches, and furnishes us with many other and varied uses. And so this element is a great wonder.* And on Psalm 134 he teaches that fire is mixed in everywhere: *And there is fire: this in the Sun, another in the Moon, another in lightning, another in the air, another that in lamps, and that which is made from wood*, etc. [Margin: St Augustine.] And St Augustine, in the appendix, sermon 59: *Sun, heat and brightness are three words, and the three are one. What is bright is hot, and what is hot is bright*, etc. [Margin: Arnobius.] Likewise Arnobius, *Against the Gentiles*, book 2: *Can you, when asked, make plain what the Moon is, what the stars are?* etc. *Why have these little fiery fragments come together through the whole body of the World?* And book 8: *Although fire kindled the stars*, etc. [Margin: Lactantius.] And Lactantius too, inveighing against the gentiles who adore the stars, book 2, chapter 6: *Now how contradictory and absurd it is that, while they affirm the heavenly fires and the other elements of the world to be Gods, they likewise call the World itself God!*

[Margin: Anastasius Synaita.] Anastasius Synaita, book 2 of the commentary on the *Hexaemeron*, indicates clearly enough that he held the same opinion, in these words: *For he who made the heaven firm out of waters, and hung the earth upon the waters, could also have kept the firmament indissoluble without water, even from the fire of the Sun.* [Margin: Theodoret.] And what of Theodoret, most

expert in Greek opinions? Having related, in the book *On Matter and the World*, the opinions of the Philosophers on the fiery nature of the stars, he then says, in book 1 *On Providence*: *For this reason, then, although so great a fire revolves around this — namely the Firmament — that is, the fire of the Sun, the Moon and the other stars, yet in so many revolutions of years it is neither melted and poured off, nor dries up, nor burns, unconsumed.* For by fire, as he continues in the same place, metals are melted, mud and marshes dried, stones baked, wood and straw set alight. *But the nature of the heaven suffers none of these things; for what appears icy in it is not melted and poured off, although so great an abundance of fire is present to it*, etc. And on Psalm 148: *He commanded the immense fire of the luminaries to run between the waters of the Firmament compressed into a cloud. Water and fire are opposed to each other; and yet neither is the fire extinguished by the water, nor is that compressed water consumed by the immense fire.* [Margin: Procopius.] Procopius, chapter 1 on Genesis, subscribes to this entirely. For when he had said, *The Sun, Moon, Stars, whose substance is fiery*, he says: *Lest they should dissolve the congealed heaven, an abundance of waters was placed by God in the upper region of the heaven, so that it might keep it unharmed by the heat of the fire.* [Margin: Alcuin.] [Margin: Bede.] In the same way Alcuin, in the questions on Genesis, and Bede, in the book *On the Nature of Things*, chapters 5 and 19, reply to the question of what nature the heaven and the stars are, that they are *of a fiery and subtle nature*. [Margin: St Anselm.] And St Anselm of Canterbury, book 1 *On the Image of the World*, chapter 23, says: *The Sun is spherical in form, fiery in nature, surpassing the earth eight times in size* — unless perhaps we should read *eighty times — the body of the Moon is globular, fiery in nature, but mixed with water.* [Margin: Isidore.] Further, St Isidore, book 3 of the *Etymologies*, chapter 48: *The Sun, while fiery*

, grows hotter still from the excessive motion of its revolution. And Blessed Peter Damian, sermon 1 on the Epiphany: *For a star is of a fiery nature.* [Margin: The Master.] As for the Master's statement, in book 2, distinction 14, that St Augustine agrees with those who say that the stars and luminaries were made of fire, it is perhaps drawn from the book *De Genesi ad litteram*, chapter 4, and from book 2 of *De Genesi ad litteram*, chapter 3. And certainly St Thomas and St Bonaventure, on book 2 of the *Sentences*, distinction 14, question 1, article 1 or 2, and Tannerus, *On the Heavens*, questions 2 and 3, say that St Augustine and a number of the Saints held, following Plato, that the celestial bodies were made of the elements, or of fire.

It is clear, then, how many weighty authors this opinion has on its side; and so we can by no means oppose it, if we ought to revere antiquity and the chief masters in the Church more than certain more recent writers who are too much devoted to the Peripatetic school. Had these men seen the many faculae which the Sun continually throws out — as our age has seen by the benefit of the telescope, according to what was said in book 3, chapter 3, and is to be said more fully here in section 4, chapter 12, numbers 19 and 20 — they would surely have changed their opinion. And indeed, as Scheiner rightly argues in book 4 of the *Rosa Ursina*, part 2, chapter 22: since Scripture says, in Ecclesiasticus

17, *What is brighter than the Sun?*, and the faculae that appear in the Sun are brighter than the rest of the Sun's surface, then if they were not parts of the Sun, something would be brighter than the Sun. And no one who has looked at the Sun through a telescope will deny that these faculae are formally flames.

This is supported, in the first place, by the Hebrew name *Or*, or *Ur*, which signifies the Sun and light, as Pagninus teaches in the *Thesaurus linguae sanctae*, from page 46. From the word *Or* is derived *Maor*, which signifies a luminary, as we have it in Genesis 1, verse 16, and Psalm 74, verse 16. Hence the Greeks probably took the name οὐρανὸς [Greek: ouranos, "heaven"] as from a first root. But *Ur* signifies the flame of fire, and not only light, as is clear from Isaiah chapter 31, verse 9, and chapter 47, verse 14. So in Genesis 15 it is said, *I brought you out of Ur of the Chaldeans*, that is, out of the fire of the Chaldeans, as Cornelius à Lapide, with others, interprets it on chapter 11 of Genesis. The Hebrew names of the Sun also strongly support it: *Chamah*, which signifies heat; *Schemes*, which signifies "There is fire"; and *Cheres*, which signifies dryness. That the Sun is hot formally, and not only virtually, is taught by Tellez, Resta, Scheiner and Salianus, cited above.

Quæſtio 5. Cur Moyſes Solem & Lunam Luminaria Magna; & illum luminare maius, hanc luminare minus appellarit.

Question 5. Why Moses called the Sun and the Moon great Luminaries, and the one the greater luminary, the other the lesser luminary.

XIII. This question is not useless to the astronomer, since the Copernicans misuse the words of Moses to establish that sacred Scripture speaks about physical things not with the rigour of truth but to suit the understanding of the common people, or according to appearance [?]; and so, when it says that the Sun rises, moves, and so on, it is to be understood according to appearance. "For look," they say, "Scripture calls the Sun the greater luminary, although it does not subtend more minutes in the sky, in its diameter, than the Moon; and it calls both a great Luminary — that is, according to appearance, since otherwise the Moon is in reality smaller than many Fixed Stars and than the other Planets."

But although we grant that the Moon is in reality of smaller bulk than other stars, and that it appears great on account of its nearness to the earth, it nevertheless deserves the name of a great Luminary. [Margin: Why the Moon is a great Luminary.] *First*, in its character as a Luminary, because it fills and illuminates the whole sublunary hemisphere with its light far more fully than all the Fixed Stars together. For this reason St Basil, in the *Hexaemeron*, homily 6; St Ambrose, book 4 of the *Hexaemeron*, chapter 6; Iunilius on the *Hexaemeron*; Procopius on Genesis; Comestor, chapter 6 of the *Scholastic History*; and Steuchus in the *Cosmopoeia* affirmed that these Luminaries are to be called great not so much comparatively as absolutely. Above all St Augustine, book 2 of *De Genesi ad litteram*, chapter 16, concludes in these words: *For certainly let them grant this much to our eyes: that it is manifest that it shines over the earth more fully than the rest, and that the day does not grow bright except by the light of*

the Sun; nor does the night, with so many Stars appearing, shine so, if the Moon is absent, as when it is illuminated by her presence. For this reason they were called φωστήρες [Greek: phōstēres, "luminaries"] by the Seventy translators — that is, not great bodies, nor great stars, but specifically great Luminaries. *Secondly*, it is great on account of its efficacy and its power, greater and more perceptible to sublunary nature, as St Thomas, part 1, question 70, article 1, reply to 5, and Vielmius, lecture 21 on Genesis, teach together with St Chrysostom. *Thirdly*, from its fellowship and likeness with the Sun, which is absolutely great: the full Moon appears equal to it, so that if the Sun is great, the Moon too can be called great relatively to the Sun. *Lastly*, the Moon cannot be understood to be great in real magnitude if it is compared with many Planets and Fixed stars, because that conflicts with the plain demonstrations of the Astronomers; and therefore we are compelled to take the word "Great" here according to appearance, with St Thomas on book 2 of the *Sentences*, distinction 15, question 1; Carthusianus on Genesis, article 12; and Cajetan and Tostatus on chapter 1 of Genesis.

But when sacred Scripture says that the Sun moves and the Earth stands still, no inconvenience follows from these words taken literally, nor any manifest absurdity; and therefore it must be understood not merely according to appearance but according to truth: that the Sun really moves and the Earth really stands still. One is ashamed, indeed, to report the fables of the Talmudists, who say that the Moon was at the beginning of equal bulk with the Sun, but was afterwards diminished because she dared to ask God that the Sun's splendour be lessened; or because an Angel flying through the air touched the Moon with his wing and darkened her — as Vives [Juan Luis Vives], book 3 *On the Truth of the Christian Faith*, Lyranus in the *Postills*, Tostatus on Genesis, and Carthusianus in the same place, article 12, report.

XIV. God, moreover, called the Sun the greater Luminary: *First*, by reason of its bulk, since the Sun is in reality the greatest of all the stars, and is not merely twenty-seven times greater than the earth, as Anaximander thought (on the report of Plutarch, book 2 of *De placitis*, chapter 2, and of Theodoret, book 4, which is *On Matter and the World*), but much greater, as is clear from what was said in book 3, chapter 11. *Secondly*, inasmuch as it is a Luminary — that is, by reason of the splendour with which it rules the day and surpasses the splendour of all the stars even taken together. So the Sun is named *Sol* by the Latins, because it alone [ſolus] shines and, having overwhelmed the other stars with its brilliance, alone appears. *Thirdly*, because it is the fountain of light, and therefore greater not only than the other planets but also than the Moon — that is, more independent, because the other Planets receive their primary light from the Sun, as we showed in book 7, section 1, chapter 5. *Fourthly*, by reason of its position, because it stands in the middle of the Planetary system, or in the fourth place. *Fifthly*, by the simplicity of its motions, since it never departs from the Ecliptic, and is for that reason the rule of the other motions and the regulator of the times. [Margin: Psalm 18.] Therefore [?] David rightly likens

it not only to a bridegroom coming forth from his chamber but also to a giant, and for a number of reasons it was called the greater Luminary by God.

[Margin: Encomia of the Sun, and its encomiasts.] Accordingly we read those rivers of sacred eloquence poured out in its praise — praise which redounds at last to the praise of its maker: Gregory Nazianzen, oration 2 *On Theology*, which is the 34th; Basil, homily 6 on the *Hexaemeron*; Ambrose, book 4 of the *Hexaemeron*, chapter 1; Chrysostom, homily 6 on Genesis; Tertullian, book 2 *Against Marcion*; to whom add Cicero, *On the Dream of Scipio*, and Macrobius on it, and Pliny, book 2, chapter 6. Gathered together from these authors, the Sun is called the eye of the world, the heart of the heaven, the delight of the day, the beauty of nature, the prince of the Planets, the King of the stars, the regulator and norm of the times, the fountain of lights; and by Pliny, though not very aptly, the soul and mind of the whole World. More correctly and more magnificently Ecclesiasticus, chapter 43, calls it *a wondrous vessel, the work of the Most High*.

[Margin: The chariot of the Sun taken from the chariot of Elijah.] As for the Poets and Painters having given it a four-horse chariot, listen to St Chrysostom, who for that reason compares it with Elijah — or compares Elijah with the Sun, which in Greek is called Ηλιος [Greek: hēlios, "sun"] — and says that the occasion of this fable was taken from the rapture of Elijah. For in the homily on the ascension of Elijah he says: *Hence, I believe, the Poets and painters took their models in depicting the image of the Sun: he who, himself glowing and radiant, in a chariot with shining horses, is raised from the wave of the Ocean and, escaping between the steep crags of the mountains, seems to ascend as it were to the heavens, is brought in in the likeness of its light. For the Sun in the Greek tongue is called Helios. Hence Elijah is truly Helios, since in a chariot with horses shining with fire he ascends from the wave of the Ocean, that is, from the turmoil of the World, advancing by the crags of the mountains, that is, by the hardships of great labours, borne up to the heavens.*

[Margin: The horses of the Sun.] The names and offices of the four horses of the Sun, according to Fulgentius, book 1 of the *Etymologies*, are taken from the four seasons of the year, or rather from the division of the ancient hours. For *Erytraeus* in Greek means "reddening", because in the morning the Sun rises ruddy; *Acteon*, again, means "shining" and "purged of vapours", which happens about the third hour of the day;

Lampos, when, the sixth hour completed, it reaches the navel of the day; and finally *Philogeus*, when at the end of the ninth hour it inclines downward towards the earth — for *Philogeus* means, as it were, "loving the earth".

Quæſtio 6. An Sol quarta die poſitus ſit in puncto cæli Solſtitiali, an in Aequinoctiali, & cuius Aequinoctij? Luna verò in Plenilunione, an in Nouilunio?

Question 6. Whether the Sun, on the fourth day, was placed at the solstitial point of the heaven or at an equinoctial point, and of which Equinox? And the Moon: at Full Moon, or at New Moon?

XV. [Margin: The star was made in the heaven, not outside the heaven.] I assume here that the words *He set them in the firmament of heaven* do not mean that God made the Luminaries and stars outside the heaven and then carried them over into the heaven — as Anastasius Synaita alone among the Fathers, so far as I know, said, book 4 on the *Hexaemeron*. They mean that he set them by making them, or made them by setting them, in the heaven itself, as St Augustine, *On Genesis, the unfinished book*, chapter 13, and Procopius and Catherinus on Genesis learnedly explain; and that this *set* is to be referred not so much to their placement as to the end and office for which they were made, and is to be joined at once with the words *that it might shine*, etc. This assumed, the question whether in the first instant in which it was established the Sun was at the summer Solstice, as Mercator and Kepler hold, or at the equinoctial point of the vernal Equinox, as many hold, or rather at the point of the Autumnal Equinox, belongs to the controversy whether the World was created in Spring, in Autumn, or in summer. We treat that at length in book 2 of the *Chronology*, chapters 4 and 16, and to those places we refer the Reader.

[Margin: Whether the Moon was established at Full Moon or at New Moon?] As to the second controversy, about the Moon: Anastasius Synaita, in the Commentaries on the *Hexaemeron*, book 4, says: *When God had made these two Luminaries, he at once fixed the great one, namely the Sun, at the East of the firmament, and the Moon at the West* — from which it follows that the Moon was opposite the Sun and full of light. Moreover the Fathers of the synod of Palestine, as Bede reports in volume 2, in the short work *On the Vernal Equinox*, meeting under the presidency of Theophilus by the authority of Pope Victor, concluded that the World was made in Spring, because of the words of Genesis 1, *Let the earth bring forth green grass*; and at the Equinox, because for the words *and he divided the light from the darkness* they read *He divided between light and darkness equal parts*; and that on the fourth day of the World there was a Full Moon, because God made both a great Luminary — that is, perfect in its apparent magnitude — and ordered the Moon to rule the night; but it would not have begun to rule the night unless it had shone the whole night, and so had had full light. Of the same opinion were not only Bede himself, on the *Hexaemeron* and in the book *On the Reckoning of Time*, but also Procopius on chapter 1 of Genesis; St Damascene, book 2 *On the Faith*, chapter 7; Abulensis on chapter 1 of Genesis, question 25; and Lyranus in the *Postills*; and St Thomas thinks the same probable, part 1, question 70, article 2, reply to 5.

On the other side St Augustine, book 2 of *De Genesi ad litteram*, chapter 15, although he defines neither absolutely, and affirms that *whether God made the Moon at its first day or full, he made it perfect*, nevertheless inclines to the New Moon. For it ought to begin at the beginning of its month; otherwise it would have begun to move not on the first but on the fourteenth day of the Moon, and, once made, it would at once have begun to wane, when it ought rather to wax. But Pererius, book 1 on Genesis, page 93, and Suarez, book 2 of *De opere sex dierum*, chapter 9, number 10, touch on this question and settle on

neither side. Suarez adds, however, that some, taking a middle way, said that the Moon was made at quadrature, that is, as it usually shines on the seventh day from its synod with the Sun. [Margin: Suarez's slip in Astronomy.] But the reason which he at once adds contains a blunder and a slip of the pen, or of the imagination, in Suarez. For he says: *In the disposition which it usually has on the seventh day: because it then rises above our horizon when the Sun sets, and so could illuminate the whole night.* Yet on the seventh day the Moon is on the Meridian, or near it, when the Sun sets, and illuminates then not the whole night but half of it.

[Margin: The Author's opinion.] For my part, if we look to authority, I incline to the Full Moon; indeed, I add other reasons too. Just as God willed that this should be the first month of the spring season, whose full moon fell either on the day of the vernal Equinox or after it — as I taught, with the Fathers and the Catholic Church, in book 1 of the *Chronology*, chapter 28 — so it is very probable that the first year of the World began at the vernal Equinox, and that he placed the Sun either at the beginning or in the fourth degree of Aries, so that together with that beginning he joined the fourteenth-day Moon, that is, the Full Moon. Thus afterwards, in the waning of its light, the Moon would show itself to be the lesser luminary by this title too, or would be *the Luminary that wanes at its consummation*, that is, when it has reached the highest perfection of its apparent light. And it was fitting that the aspect of the Moon to the Sun at the beginning of the World should be such as it was when the World was restored through the death of CHRIST.

Now, with the cycle of sabbatical years carried back to the beginning of the World: if we wish the World to have been established in one of those years that were Sabbatical, and in such a way that the Full Moon or the New Moon fell on the day of the vernal or the autumnal Equinox; and the World to have been created in the century that preceded the Epoch of Christ by 4000 years, as we showed in book 2 of the *Chronology*, chapter 15 — then from astronomical calculation only four years present themselves to me as probable for the beginning of the World, on account of the characteristics already mentioned. I have chosen to show them in the following small table, in which we have computed the years and months in the Julian manner, adding the weekday on which the Equinox and the new or full Moon fell together.

Years before the first year of CHRIST, all Sabbatical	Concurrence of the lunar syzygies with the day of the Equinox, and their time	D.	H.	Week-day

CAPVT V.

Chapter V.

CAPVT V.

Sitne Cælum Simplex corpus, an Compoſitum ex Forma & Materia diuerſa ab elementari, an eiuſdem rationis cum elementari? & ſi ex hac, Ex quonam elemento?

Whether the Heaven is a Simple body, or Composed of Form and of Matter different from the elementary, or of the same kind as the elementary? And if of the latter, of which element?

Quæſtio 1. De Simplicitate & Compoſitione Cæli.

Question 1. On the Simplicity and Composition of the Heaven.

I. [Margin: 1. Opinion: on the simplicity of the heaven.] The FIRST Opinion was that every heaven is a simple body, that is, not composed of matter and form really distinct. First, because Aristotle seems to have asserted it; next, because we have no argument from change by which to infer that there is in the heaven matter receptive of contraries, or of an alteration tending to the corruption of one substantial form and the generation of a new form; again, because that matter, if it were truly matter, would seek one form after another, and since these are denied it, that appetite would be in vain, and it would be violently and perpetually deprived of them; finally, the perfection of the Universe requires that there be in it this grade of substance too, that of a fifth essence and of an altogether simple body. For it cannot be demonstrated that a created corporeal substance which is simple is impossible. [Margin: Authors for the simplicity of the heaven.] So judged Averroes, in the book *On the Substance of the Orb*, chapter 2, and on book 8 of the *Metaphysics*, comment 12, on book 12, comment 20, and on book 1 *On the Heavens*, comment 20; Zimara [Marcantonio Zimara], theorem 107; Faber, theorem 59; Antonius Andreas on book 8 of the *Metaphysics*, question 4; Iandunus [Jean de Jandun] in the same place, question 7, and on book 1 *On the Heavens*, question 23; Saxonia [Albert of Saxony] on book 1 *On the Heavens*, question 4, article 1; Caietanus Thienensis [Gaetano da Thiene] on book 1 of the *Physics*, question 21; Piccolomini [Francesco Piccolomini], *On the Heavens*, chapter 106; Achillinus [Alessandro Achillini], book 1 *On the Orbs*, question 1; and, among the Scholastics on book 2 of the *Sentences*, Durandus [Durand de Saint-Pourçain] and Gabriel [Gabriel Biel], distinction 12, question 1 or 2; Maironus [François de Meyronnes], distinction 14, question 2; and Bassolius, question 1, article 4. And certainly Aristotle, if he is understood in the plain sense and without forced interpretation, teaches in book 1 *On the Heavens*, from text 20 and from text 121, that the heaven is ingenerable and incorruptible, like the Intelligences, because it has no matter; and in the same place, chapter 2, he infers from simple and circular motion that it is a simple body; and in book 12 of the *Metaphysics*, text 10, where he treats this question on purpose, he concludes: *But all things that change have matter, but a different matter; for even of the everlasting things themselves, those that are not generable but movable by locomotion have matter — not, however, matter apt for generation, but for motion from a place and to a place.*

II. [Margin: 2. Opinion: on the composition of the heaven.] The SECOND Opinion was, and is, that the heaven is composed of Matter and substantial form. To some, an argument for such a composition has seemed almost necessary: both because it falls under the senses, and because of quantity, rarity, density, local motion and, in short, physical change. Thus, finally, besides the philosophers and the Fathers who say that the heaven consists of one or more elements, [Margin: Authors of the 2nd Opinion.] this is the view of St Thomas, part 1, question 66, articles 1 and 2, on book 1 *On the Heavens*, lecture 6, and on book 8 of the *Physics*, lecture 20 — granted that earlier he seems to have inclined to the former opinion, on book 2 of the *Sentences*, distinction 12, question 1, article 1, on book 8 of the *Metaphysics*, chapter 14, and in the *Disputed Questions*, the question *On Spiritual Creatures*, article 6, reply to 2. So too Avempace [Ibn Bājja], as reported by Albert on book 1 *On the Heavens*, tractate 1, chapter 3; Avicebron [Solomon ibn Gabirol] in the book *Fons vitae*; Plotinus, book 1, Ennead 2, question 1; Simplicius on book 2 *On the Heavens*, comments 3 and 35; Philoponus on the 6th and 13th of Proclus; Avicenna, book 1 of the *Sufficientia*, chapter 2; Niphus [Agostino Nifo], *On the Substance of the Orbs*, comments 39 and 42; Soncinas on book 12 of the *Metaphysics*, question 7; Iavellus [Crisostomo Javelli] on book 8 of the *Metaphysics*, question 12; Soto [Domingo de Soto] on book 2 of the *Physics*, question 1; Flandres [Dominic of Flanders] on book 8 of the *Metaphysics*, question 7; Paulus Venetus [Paolo Veneto], *On the Heavens*, chapter 1, who attributes it to Themistius and Theophrastus; Aegidius, in the treatise *On the Matter of the Heaven*; Gianninus, *On the Nature of the Heaven*, part 1, chapter 21; the Coimbra commentators, *On the Heavens*, book 1, chapter 2, question 4; Rubius [Antonio Rubio] in the same place, question 5; Suarez, disputation 13 of the *Metaphysics*; Hurtadus [Pedro Hurtado de Mendoza], disputation 1 *On the Heavens*, section 1; Moris., disputation 2 *On the Heavens*, doubt 2; Amicus [Francesco Amico], tractate 4, question 2, doubt 2; Tannerus, *On the Heavens*, question 3; Arriaga, disputation 2 of the *Physics*, section 11, subsection 2; and Oviedus, the single controversy *On the Heavens*, part 2.

Among the Scholastic Theologians, moreover: Capreolus and Ocham [William of Ockham] on book 2, distinction 12, question 1; St Bonaventure on book 2, distinction 12, article 2, question 1; Aegidius on book 2, distinction 12; Alensis [Alexander of Hales], part 2 of the *Summa*, question 44, member 2; Hervaeus [Hervaeus Natalis], *Quodlibet* 4, question 3; Albert the Great, part 1, question 4, *On the Four Coevals*, article 3; and Carthusianus on book 2, distinction 14, question 1, who says that the opposite is erroneous, indeed contrary to Aristotle. For they try to draw Aristotle to their opinion, on the ground that in book 8 of the *Metaphysics*, texts 3 and 10, he says that every sensible substance consists of matter; and in book 1 *On the Heavens*, chapter 9, from text 93 to 95, that there cannot therefore be another heaven, because this one that we see consists of the whole of matter; and again, in book 12 of the *Metaphysics*, text 22, and book 2 *On Generation*, text 51, that the principles of all sensible things

are the same, matter and form. But in these places Aristotle takes matter for a corporeal and sensible entity which is the subject of sensible accidents, not for matter really distinct from the form, which he usually calls the matter of Generation. And when in book 7 of the *Metaphysics*, text 5, he seems to say that the heaven and the stars are from the elements, in fact he does not say this in the Greek text, but that these are substances, like the elements, the mixed bodies and all natural bodies.

III. [Margin: 3. Opinion: problematic, or distinguishing.] The THIRD opinion, then, either thinks each of the two former probable, as Zerbus [Gabriele Zerbi] does on book 8 of the *Metaphysics*, question 3, or distinguishes. For Scotus on book 2, distinction 14, question 1, Aversa, question 33, section 5, and Mastrius and Bellutus, disputation 2 *On the Heavens*, question 2, article 1, say that, if one looks to the authority of Aristotle, the Heaven is not composed of matter and form; but, if one looks to the authority of many theologians and to the truth, it is composed of matter and form. Ioannes Poncius [John Punch], on the other hand, himself also a Scotist, disputation 22 of the *Physics*, question 1, concludes that if reason is regarded it is uncertain whether the heaven is simple or composite, but if authority is regarded it is more probable that it is composite. I, for my part, use a threefold distinction, for which let the following stand.

I. CONCLVSIO.

Conclusion I.

[Margin: 1. Conclusion.] *The visible Heaven, if the authority of Aristotle is regarded, is a Simple body, that is, one having matter, but matter not really distinct from the substantial form.* This is clear enough from the passages of Aristotle cited at the end of numbers 1 and 2.

II. CONCLVSIO.

Conclusion II.

[Margin: 2. Conclusion.] *The visible Heaven, whether one regards the authority — resting on Sacred Scripture — of many Philosophers, ancient and recent, and of many Fathers, Doctors of the Church and Theologians, or the more probable reason, is not simple, but consists of matter and form really distinct from each other.*

For nearly all the Philosophers before Aristotle held that the heaven consists of one or more elements, or was generated from their matter, as will be clear from what is to be said in the following chapter. And very many of the Fathers affirmed that the heaven — either all of it, or indefinitely, or at least the Eighth sphere — was made of elementary water solidified in the manner of ice or crystal, and moreover that above the heaven there is an aqueous heaven consisting of true, elementary water. I have already cited them at length for this purpose in chapter 2, questions 1 and 3, where we also showed that this agrees closely with Sacred Scripture understood literally (as indeed it ought to be understood, since no inconvenience follows from it). Not a few, too, affirm that the starry

heaven is Fiery, indeed that it is the fourth element itself, fire; these I cited both in chapter 1, question 4, and in chapter 3, conclusion 4, argument 5. Finally, several assert that the Planets and the other stars are either fiery, or of earth, or of fiery vapours; these I reviewed in chapter 4, question 4, from number 10. To say that these authors speak metaphorically, or analogically, or because the stars are hot only virtually and not formally, is not to take their meaning in its plain and obvious sense; indeed it conflicts with the reasons of some of them, who thought that waters were kept in the heaven and above the heaven to temper the stars' heat. A distinction of this kind arises only from a presumed opinion about the simplicity of the heaven, whether on account of the authority of Aristotle or on account of the reasons indicated in number 1, which are presently to be resolved. Therefore the first part of the conclusion remains sufficiently proved.

[Margin: 1. Argument for the affirmative [?] side.] The second part of the conclusion is proved, *First*, from the new Stars and from certain comets, or hairy stars, some of which were more probably in the heaven, that is, above the Moon, as we showed in book 8 in the conclusions of the chapters — and indeed generated in the same way as the spots and faculae of the Sun are usually generated, according to what was said in book 3, chapter 4. [Margin: 2. Argument.] *Secondly*, because either the grades of beings are not to be multiplied without grave necessity and solid foundation (and this multiplication is greater than that of two really distinct entities within the order of composite being); or, if they are to be multiplied, and a simple substance is required for perfecting the Universe, it suffices that the Empyrean Heaven, which is invisible to us, be of this kind; nor is it necessary that every heaven, or any of the visible ones, be such. [Margin: 3. Argument.] *Thirdly*, although sensible Quantity, rarity, density, opacity, transparency, light, colour and the other accidents of this kind are not necessary indications of composition from matter and corporeal form, yet so long as we do not know of the simplicity from elsewhere, they are rather indications of such matter and composition. This is on account of the kinship they have with the other sensible accidents that accompany such a composition — indeed with themselves, taken in kind and considered in so many elements and mixed bodies, by reason of which the presumption and possession stand in favour of composition and of corporeal matter and Form.

Nor is a physically evident substantial transmutation required for this probable indication; otherwise it would no longer be a merely probable argument for composition, but an evident one. And those who think that the heaven consists of elementary matter, or of some element, will say that a sufficient indication of this change is had in that part of the element which is near the earth, and that it is not necessary that such changes occur in every part of it. For if there is some part of the earth, or of the air, never substantially transmuted since the beginning of the world, it is not for that reason to be called simple. [Margin: Solution of the objections.] And so one of the reasons usually brought for the first opinion is resolved. The reason drawn from the incorruptibility of the heaven will be resolved from what is to be said in chapter 6. As for the appetite

for other forms, which seems to be a property following from matter in the fourth mode — since otherwise, if matter sought only one form, it would not seem to have potentiality and indifference to several — it can be replied that such an appetite is in it only on the supposition that it is deprived of its former form, and that there is an agent which intends, and is able, to introduce another form; and God is undoubtedly an agent of this kind.

Quæſtio 2. De ratione Materiæ, ex qua Cælum conſtat.

Question 2. On the nature of the Matter of which the Heaven consists.

IV. [Margin: 1. Opinion: the Matter of the Heaven is different from the elementary.] The FIRST Opinion is that the Matter of the celestial Bodies is of a different kind from the matter of the bodies that are subcelestial or lower. Aristotle would certainly have defended this opinion (book 1 *On the Heavens*, chapter 2, and book 1 of the *Meteorologica*, chapter 3) if he had thought that the heaven consists of matter distinct from form. Taken absolutely, however, the holders of this opinion were Simplicius, Theophrastus, Alexander of Aphrodisias, Avicenna and Algazel [al-Ghazālī]; likewise Albert the Great on book 2 of the *Sentences*, distinction 14, question 2, and in book 2, part of the *Summa*, tractate 11, question 53; Alensis, part 2 of the *Summa*, question 50; Gulielmus Parisiensis, book *On the Universe*, part 1, chapter 39; St Thomas, part 1, question 66, article 2, and on book 2 of the *Sentences*, distinction 14, question 1, and in book 2 *Against the Gentiles*, chapters 18 and 20. He is followed there by Ferrariensis [Francesco Silvestri], Caietanus, Capreolus, Durandus, Bannes [Domingo Báñez] and Zumel [Francisco Zumel]; and likewise by Riccardus [Richard of Middleton] on book 2, question 8; Hervaeus; Zabarella [Jacopo Zabarella] in the short works *On the Matter of the Heaven*; Gianninus, *On the Nature of the Heaven*, part 1, chapter 21; Suarez, disputation 13 of the *Metaphysics*, section 11; Valentia [Gregorio de Valencia], part 1, disputation 5, question 2, point 1; Pererius, book 2 on Genesis, question 1; Fonseca [Pedro da Fonseca], book 5 of the *Metaphysics*, chapter 4, question 2; Amicus, tractate 4 *On the Heavens*, question 3, doubt 1, who adduces for it Flandres, Achillinus, Soncinas, Niphus, Mersennius, Pavesius and Piccolomini; Tannerus, *On the Heavens*, question 3; Rubius, book 1 *On the Heavens*, question 5; Aversa, question 33, section 5; and Poncius, disputation 22 of the *Physics*, question 2.

Among the Astronomers, too, Tycho Brahe, in the letter to Rothmann of the year 1588, August 17, page 106: although he admits a fluid heaven, he does not admit that it is of air, as Io. Penna [Jean Pena] and Rothmann contended. Indeed he says: *But that it is of air, or shares in any elementary nature, I shall by no means admit; for far be it that anything elementary, corruptible and variable, etc., be stitched onto the most pure and most perfect celestial nature, which is subject to no changes.* And shortly after: *for all unanimously and most certainly lay down that the heaven is wholly exempt from the number and nature of the four elements, and displays a certain more excellent nature; and therefore that it is a certain fifth essence, wholly different from those four elementary ones.* Then he taunts the Theologians

who, understanding Moses too little aright, said that the heaven consists of watery matter; and he concludes that, although it is uncertain of what nature the heaven is, and inscrutable to us, it is certain that it shares in no elementary nature. He confirms this in the letter of the year 1589, February 21, from page 137.

V. [Margin: Arguments for the 1st opinion.] The arguments for this opinion are these. *First*, the authority of St Dionysius, book 1 *On the Divine Names*, chapter 4, who says that the celestial bodies *are of such a nature and essence as can neither grow nor diminish, nor be changed in any part*; and of St Basil, homily 3 on Genesis, who says: *But we are not pleased to assert that the Firmament is made either of one of the simple bodies or as a mixture of them all: for we have already been so instructed by divine scripture itself that we may not think or imagine anything beyond what has been granted to our mind.* But from these passages nothing more is gathered than that the heaven is incorruptible, and not actually composed of elements.

Secondly, the same thing seems to be proved by the simplicity of celestial motion, the nobility of the spherical shape, the eminence of its place, the predominance of its influences, its independence from lower things, the perfection of the Universe, which requires this grade of matter, and above all the natural ingenerability and incorruptibility of the heaven. For it is to these heads that the reasons, set out at greater length by the champions of this opinion, are finally reduced. But some of these reasons are topical and have very slight probability; others prove only the nobility and excellence of the form, to which incorruptibility would be due. Therefore, although the incorruptibility of the heaven is defended better, and with greater dignity to the heaven, if it is said to have a different matter, as Suarez and Amicus say above, it still does not follow from natural incorruptibility that the matter of the heaven is of a different species from sublunary matter — as Arriaga notes, together with Molina [Luis de Molina], disputation 2 of the *Physics*, section 11, subsection 2. Granted, Suarez (disputation 13 of the *Metaphysics*, section 11, from number 14) contends that the heaven would of itself be corruptible no less than the elements if it consisted of the same matter: for that, he holds, it is enough that the matter have the privation of some form which it is proximately or remotely apt to have; and so the heaven would be generable *per se* from air, and air from the heaven, even if *per accidens* an agent capable of introducing such a form were lacking. The solution of this controversy therefore depends on the question of the incorruptibility of the heaven, which is to be treated a little below.

VI. [Margin: 2. Opinion: on matter of the same kind.] The *Second* opinion is that the visible heaven has matter of the same kind as the matter of sublunary things. This opinion was held not only by the ancient Philosophers, or by those more recent thinkers who supposed that the heaven and the celestial bodies consist of one or more elements, but besides them by Avicenna, book 1 of the *Sufficientia*, chapter 4; Avicebron, as reported by St Thomas; Scotus on book 2, distinction 14, question 1; St Bonaventure on book 2, distinction 12,

article 2, question 1, and distinction 14; Ocham in the same place, question 22; Aegidius in the treatise *On the Matter of the Heaven*, and on book 2, distinction 13; Gabriel on book 2, distinction 12; Abulensis on chapter 1 of Genesis; Moris., disputation 2 *On the Heavens*, doubt 3; Angestus, book 1 *On the Properties of Matter*, proposition 9; Molina, the tractate *On the Work of the Six Days*, disputations 2, 3 and 5; Scaliger, exercise 61; Mastrius and Bellutus, disputation 2 *On the Heavens*, question 2, article 2; Baltazar Tellez [Baltasar Teles] on the *Physics*, disputation 40, section 1, number 22; Salian in the *Annals of the Old Testament*, on the second day of the world; and Francisco Oviedus, the single controversy *On the Heavens*, point 2.

The arguments for this opinion are these. *First*, because a specific diversity of matters seems impossible, since every distinction of species and genera comes from the Form, according to Aristotle's saying in book 7 of the *Metaphysics*, text 49: *It is the act that separates, or distinguishes.* This saying, however, admits many explanations, and the opponents will say that substantial Form constitutes the Physical species, but not every species, or the metaphysical essential nature; and Suarez, disputation 13 of the *Metaphysics*, section 11, number 8, teaches at length that a specific diversity of matters involves no contradiction. *Secondly*, because if anything compels us to posit a different matter, it is the incorruptibility of the heaven; but this incorruptibility can stand even if the matter of the heaven is of the same kind. For its natural incorruptibility can belong to the heaven either by reason of a form that does not have contrary qualities capable of being overcome by the qualities of other bodies, or because it lies outside the hazard and the sphere of the sublunary agents — although that incorruptibility has not yet been demonstrated, nor is it demonstrable. *Thirdly*, and most of all: very many Fathers and doctors of the Church teach that the heavens or the celestial bodies are made of water or of fire. I have cited them at length, partly in chapter 1, question 4, partly in chapter 2, question 1, and partly in chapter 3, conclusion 4, argument 5; and St Thomas, on book 2, distinction 14, article 2, says that Saints Basil and Augustine and several of the Saints, following Plato, held that the heaven is of the nature of the elements.

VII. [Margin: 3. Opinion: suspending assent.] The *Third* opinion, on account of uncertainty, or of the equal weight of reasons and authorities on both sides, either teaches that each of the preceding opinions can be held problematically, or ventures to affirm nothing definitely. Thus the Coimbra commentators, book 1 *On the Heavens*, question 6, think each opinion probable as regards the matter (for as regards the nature taken from the form, they had already determined in question 5 that it differs from the sublunary); so too Hurtadus, disputation 1 *On the Heavens*, paragraph 15, although he inclines to the second opinion; and Arriaga, disputation 2 of the *Physics*, section 11, subsection 2.

Philo, moreover, in the book *On Dreams*, puts it thus: *The heaven, however, has an incomprehensible nature, and no true knowledge of it comes down to us. For what can we pronounce about it? That it is congealed ice, as some hold? Or the*

purest fire? Or a certain fifth body, movable in a circle, akin to none of the four elements? What of that outermost sphere of the fixed stars — has it solidity, or only a surface without depth, like figures painted on a plane? With equal restraint St Basil, speaking of the Firmament in homily 3 on the *Hexaemeron*, says that he is not pleased to assert that the heaven is made of one element or mixed from all, because he has learned from divine Scripture to think nothing beyond what has been granted. And St Damascene, book 2 *On the Faith*, chapter 6, after reviewing various opinions, concludes: *But there is no need to search into the substance of the heaven: it is unknown to us.*

But let us hear St John Chrysostom, homily 2 *On the Incomprehensible Nature of God*: *Of what substance the heaven consists we do not know. Let him who contends, and claims to know, say of what substance the heaven is. Is it some moisture congealed into frost? Is it a condensed cloud, drawn together into a thicker substance? Is it a gross and more corpulent air? No one, surely, can teach plainly what it is.* Let us also repeat the words cited elsewhere from his homily 4 on Genesis. *But what, then,* says Chrysostom there, *shall we say this firmament is? Condensed water, or compacted air, or some other essence? No prudent man would rashly assert this: for what is said must be received by us with great modesty and gratitude; and we must not go beyond our nature and search into the things that are above us, but only know and hold among ourselves this: that the firmament was produced by the Lord's command, making a separation of the waters, so that it can hold some beneath itself and carry others on its back.* Hugo [Hugh of Saint Victor] expressed altogether the same opinion in other words but with the same sense, book 1 *On the Sacraments*, part 1, chapter 18, concluding:

But now it does not seem to me that I should labour much over questions about these things, which no reason comprehends and no authority to which faith must be given proves. Having weighed these passages, Ascanius Martinengus in the *Glossa magna*, although on page 605 he admits that God made the starry heaven on the second day from the elements or from chaos — if the plain sense of the Mosaic history and the views of the Fathers are regarded — nevertheless concludes on page 607 that the substance of this heaven is unknown and imperceptible to us. Let this, then, be the

CONCLVSIO.

Conclusion.

[Margin: 3. Conclusion.] *Although it cannot be known by us demonstratively and evidently what the substance and nature of the visible heaven is, it is nevertheless more probable that it consists of matter of the same kind as the elementary.*

VIII. The first part of the conclusion is established both by the authorities adduced for the 3rd opinion and by the mere consideration of the arguments which we said are usually adduced for the 1st and 2nd opinions; for there is none of them that exceeds mere probability. And certainly, if we once admit that corruptible and incorruptible bodies alike can have the same matter, and that corruptibility is to be sought not only from the indifference of the matter

but also from the properties of the form — according as it has or does not have qualities corruptible by contraries — or even from the nearness and power of an agent, then no way remains for us of gathering with certainty, from any change or absence of change, that the matter is different rather than not different.

The second part is proved thus. That conclusion is more probable which is gathered from sacred scripture taken literally, and according to the interpretation of several Fathers, than its opposite, so long as the opposite is not deduced from valid arguments and demonstrative reasons, or from reasons that come close to demonstrative ones. But that the starry heaven consists of matter different from the sublunary is neither demonstrated nor urged by valid arguments approaching demonstration; on the other side, that it consists of watery or fiery or some other elementary matter is gathered from sacred Scripture taken literally, and from the Fathers, as I have already taught in chapter 2, questions 1 and 3, in chapter 1, question 4, and in chapter 3, conclusion 4, argument 5. Thus Carthusianus, on book 2, distinction 14, question 2, rightly pronounces it safer, on the basis of sacred Genesis and many Fathers, to assert that the heaven is of an elementary nature. And certainly, if above the Firmament there is a watery heaven, that is, one of water of the same matter as the elementary waters, and if the Firmament itself, taken for the 8th sphere — if not the whole starry heaven — is of elementary water, as we gathered from sacred Scripture and the Fathers in chapter 2, questions 1 and 3, who then would deny that the rest of the starry heaven below the eighth sphere of the Fixed stars is of the same matter? Nor ought either the authority of Aristotle in this matter, or one or another reason of fitness drawn from Physical or Metaphysical subtlety, move us to interpret Scripture and the Fathers violently. This is all the more so since Aristotle's opinion on the diversity of celestial matter, and on a certain fifth essence, sprang from an infected root — namely from the opinion of the eternity of the World, and of the necessity by which he thought the heaven and the World were produced by God — and since it tends to insinuate to us that the heaven cannot be destroyed even by God. [Margin: St Ambrose's warning against a fifth essence.] St Ambrose gravely and prudently warned us of this, in book 1 of the *Hexaemeron*, chapter 6, in these words: *Others, therefore, considering that these things could not be stable, introduced a certain fifth nature of body, by which they supposed that the substance of the heaven would long endure. But that opinion could not withstand the Prophetic sentence, which the divine Majesty of our God, the Lord JESUS Christ, also confirmed in the Gospel.* He then brings the words of Psalm 101, *The heavens are the works of your hands; they shall perish*, etc., and those of Christ in Matthew 24, *Heaven and earth shall pass away*; and he adds: *Those, therefore, accomplish nothing who think that a fifth, ethereal body must be introduced in order to assert the perpetuity of the heaven: for they see equally that a portion of one member, joined on unlike the rest, usually brings a blemish to the body rather than otherwise.*

QUÆSTIO 3. EX QUO AUT QUIBUS ELEMENTIS CÆLUM CONSTET.

Question 3. Of what Element, or Elements, the Heaven consists.

IX. Matching the number of the four Elements, we adduced four opinions on the nature of the stars as well, in chapter 4, question 4, from number 10. Now we shall report as many on the nature of the heaven itself, to be compared with those. Further, the opinions of the ancient Philosophers on the nature of the heaven are reported by Diogenes Laertius in their lives; by Plutarch, book 2 of the *De placitis philosophorum*, chapters 11 and 13; by Theodoret in the book *On Matter and the World*; by Clement of Alexandria in the books of the *Stromata*; by St Justin in the *Admonition*; and by Mirandulanus [Gianfrancesco Pico della Mirandola], book 1 of the *Examination of the Vanity of the Gentiles*, chapter 12.

[Margin: Authors for the 1st opinion.] The *First* opinion was that the heaven is fiery — indeed that it is that very element which we call fire, though pure, and because of the rarity of its substance not suited to burning. For this opinion, in chapter 3, conclusion 4, argument 5, I reviewed the Stoics, Heraclitus, Empedocles, Pythagoras, the Egyptians, Plato and Pliny the Elder, and, among our own, Saints Augustine and Anselm of Canterbury, Innocent III, Bede, Junilius, Hugo Carensis, Delrio [Martín Antonio Delrío], Paracelsus and Balthassar Tellez. But since I see that Plato's view is doubted, what I said there must be confirmed. [Margin: Plato's opinion on the fiery heaven confirmed.] Plato, then, says in the *Timaeus*: *God first created fire and earth; but two things alone cannot cohere well without some third, and both require some middle bond.* Then, after a little: *By this conjunction the World was so compacted that it can be seen and touched. Hence the body of the World was forged out of things of this kind, four in number.* And shortly after: *The World therefore received each of these four things entire; for its maker composed it from all the fire, air, water and earth, in such a way as to leave no part or power of any of them outside.* From these passages Plotinus, Porphyry, Taurus, Marsilio Ficino and very many Platonists gather that the World consists of these four bodies alone, and that, since the highest of them is fire, the heaven is nothing other than Fire. So too Philoponus, disputation 13 against Proclus, chapters 15 and 18, teaches that for Plato the heaven is the same as fire; and Nemesius in the book *On the Nature of Man*, and St Gregory of Nyssa, book 3 of the *Philosophy*, chapter 4, say that Plato asserts that the heaven which Aristotle calls the fifth essence consists of Fire and Earth.

Nor is it an obstacle that Plato counts five kinds of souls — earthy, watery, airy, fiery and ethereal — among which in the *Epinomis* he distributes the five regular bodies, or their five figures; or that in the *Timaeus* he says that that Fire is not a burning flame but a light that illuminates gently. From these passages Io. Picus, Maynettus and Simplicius (books 1 and 2 *On the Heavens*) try to reconcile Plato with Aristotle, as though they differed only in the word, and Plato in reality acknowledged a certain fifth essence in the heaven. For, as Philoponus replies, Plato does not distinguish the fifth body of the World from the four Elements adequately, but inadequately, as a whole from its parts taken

separately, and to this whole he assigns the fifth figure; and he calls Fire ether, as being a purer air, and because of its rarity least apt for burning. Add to these the very many whom I named in chapter 4, number 12, who assert that the stars are Fiery, or are fires; and Tycho in the *Epistolae Astronomicae*, page 137, who thinks indeed that the heaven is a certain fifth essence, but that if it did consist of any element, it should rather be called fiery, because fiery stars appear in it.

[Margin: 2. Opinion: on the watery heaven.] The *Second* opinion was that the starry heaven — either all of it, or at least the Firmament, that is, the eighth sphere — is watery, with waters placed above it. How many Fathers and Doctors held this opinion we made clear in chapter 2, questions 1 and 3, setting out and expounding their own words honestly and without violence; and in the same chapter, at the end of question 1, we said that Martinengus, Molina, Delrio, Cornelius à Lapide, Serrarius [Nicolaus Serarius], Salian and Tannerus were also of this opinion. Add to these those whom I adduced in chapter 4, number 11, who affirm that the stars consist of watery vapours and are nourished by them.

[Margin: 3. Opinion.] The *Third* opinion affirms that the heaven is of air — and not only that heaven in which the birds of the sky fly (for our Tellez, disputation 40 of the *Physics*, section 1, asserts that this heaven is of air, and is truly and properly called heaven), but also that in which the stars are. For that this heaven is of the same substance as pure air, by reason of its very similar rarity and transparency, was asserted by Io. Penna the Frenchman and by Giordano Bruno in the book *On the World* against the Peripatetics, and for several years by Christoph Rothmann, as Tycho reports in volume 1 of the *Progymnasmata*, page 92, and in the *Epistolae* to Rothmann dated 1587 January 20, page 60, and again in the Letter of the year 1588, August 17, page

107; and in Rothmann's letter of the year 1588, September; and in the letter of the year 1589, February 21. Rothmann, indeed, drew his argument from the refraction of the rays of the stars, which is the same in the ether and in pure air. But Tycho teaches in the same place that this argument has no force at all; and indeed it often happens that wine and water, or some other liquid, are of different species and yet agree so closely in density that they refract rays equally. Johannes Kepler, too, seems to be reducible to this opinion. In book 4 of the *Epitome of Copernican Astronomy* he explains the Creation of the World described by Moses in such a way that the heaven of the fixed stars is a crust or wall of the Universe consisting of water or crystal, while inside it, all the way to the Sun, the centre of the world (as he himself thinks), everything is full of pure air. This air he elsewhere calls in many places the ethereal [?] aura, and the expanse, from the Hebrew name *Raquiah*; it is contained in the same way as air is contained within watery bubbles produced by blowing. These things laid down, since according to what was said in conclusion 2 it is more probable that the visible heaven consists of elementary matter, I briefly express my opinion in the following Conclusion.

CONCLVSIO.

Conclusion.

[Margin: 4. Conclusion.] *It is more probable that the Heaven in which the Fixed stars are is Watery, but that the heaven in which the Planets are is Fiery.*

X. For that proposition is more probable than the others which, if it cannot be proved by valid reasons, rests on more authorities, reconciles more authors, accords better with Sacred Scripture taken together with the interpretation of the Fathers, and does not make the Workmanship of God unseemly or ill-proportioned. Such is our conclusion. For that some visible heaven solidified out of water hardened in the manner of ice or crystal is confirmed both by the Hebrew name of the Firmament and by a great multitude of Fathers and Doctors, as we showed at length in chapter 2, question 1. Yet many Fathers and Doctors likewise assert that some starry heaven is fluid, in which the Planets move by themselves and not with the motion of the heaven, as is clear from what was said in chapter 2, question 2. I taught sufficiently in chapter 3, conclusion 4, that the former, who introduce solidity, are to be understood chiefly or only of the orb of the Fixed stars, and the latter of the heaven of the Planets, and that in this way those Fathers are best reconciled with one another — just as almost all the more recent Astronomers, in order to save the celestial Phenomena, grant solidity to the sphere of the Fixed stars alone, but affirm that the heaven of the Planets is fluid and permeable. But since the heaven of the Planets could be fluid and yet be either watery, or airy, or fiery, we are persuaded in the end by the following reasons that it is rather fiery.

[Margin: 1. Reason.] *First*: since some of the Fathers said, without distinction, that the heaven is watery, and others that it is fiery, they cannot be better reconciled than if you interpret the former of the sphere of the Fixed stars and the latter of the heaven of the Planets, and do not award the whole dispute to one party. For the reasons they adduce for that solidity apply solely to that highest heaven: namely, that solidified waters should be, as it were, the outermost walls of the world, bounding our sight, or like the shell of an egg or the vault of the world, able to sustain the upper waters on their back; and that they should contain the innumerable fixed stars scattered through the whole heaven and temper their heat, preserving that heaven until the last day of the world. Conversely, the reasons that others adduce for the fluidity of the heaven apply only to the heaven of the Sun, the Moon and the Planets. Therefore, if one of these heavens must be called watery and the other fiery, it is surely the heaven of the Fixed stars that must be called watery, and that of the Planets fiery.

[Margin: 2. Reason.] *Secondly*, some of the Fathers and Doctors speak not without distinction but distinctly, and say expressly that the heaven which they gather from the scriptures to have been made of water made firm and consolidated is the eighth sphere, or the highest of the visible heavens, which for that reason has for many centuries usually been understood by the name of Firmament. In the same way not a few teach expressly that the heaven of the

Planets is fiery, indeed is the fourth element itself, fire, as I showed by quoting the words of those Authors themselves in chapter 1, number 16, and in chapter 3, conclusion 4, argument 5; and so they suppose that this heaven — in which the Sun, or Titan, stands, and the Titanian stars, that is, the Planets, receive from the Sun their light and the law of their motion — is called Ether, that is, pure fire.

[Margin: 3. Reason.] *Thirdly*, there is the fitness of the divine workmanship. For if only the good of the elements is regarded, their natural order ought to have been such as it was at the first instant of creation: namely, that the earth should be lowest, with the abyss, that is, water of great depth, surrounding it above, and that above the waters should be both of those elements which earned their name from the thinness of spirit, namely air, and, in the highest place, fire (for we showed in chapter 1, number 13, that both are signified by the words *the spirit was borne over the waters*). Yet the good of the remaining natural bodies required another order, which God accordingly established on the second and third day: namely, that part of the earth, uncovered by the waters, should become fit to hold men and the other animals with ample lodging and dwelling, and to nourish and refresh crops, flowers, grasses and foliage; that the moister air should be left for the breathing of animals around the earth and the water, and for the flight of birds, which for the most part nest and rest on the earth; and that above it should be fire.

Moreover, a great mass of waters had been created from the beginning, as its proportion to the earth demanded — so great that it deserved the name of abyss, that is, of water having an almost unsearchable depth — and neither all of it, nor even the greater part, could fittingly be enclosed within the hollows of the Earth or in underground caverns. The supreme maker therefore, most prudently, lest he should seem to have made anything superfluous and to be destroyed immediately after creation, obtained five advantages from that superabundant mass of waters. For he raised a part of them and placed it immediately beneath the splendour of the Empyrean, so that from that mixture of light and watery opacity he might form a most beautiful and perpetual Rainbow, and refresh the eyes of the Blessed with an incredible variety of colours far more delightful than ours; and so that there might, besides, be a kind of mirror, in which and from which the bodies of the Blessed and their splendours could be reflected in an admirable and manifold spectacle. Thus that watery heaven beneath the Empyrean may be imagined as a certain vast Rainbow set around the whole firmament, whose blue and darker part is lowest, toward us, the red in the middle, and the yellow or golden highest. Next, he consolidated the remaining part into the crystalline heaven, and by its density and opacity established a boundary between the invisible heavens — namely the Watery and the Empyrean, which belong to the other life — and the visible or sensible heavens, namely the fiery and the airy. Thirdly, he fixed the non-wandering stars in this Firmament, or crystalline heaven, so that they keep perpetually the same distance from one another and move at an equal pace with the motion of

that orb. Fourthly, he immediately tempered the heat of the innumerable fixed stars by the cold and moisture of the waters already mentioned, because the fixed stars, each of them, had to stay in the same place of that heaven, and were scattered through all that heaven. This immediate tempering was not necessary for the heaven of the Planets. These are only seven; they move only within the Zone of the Zodiac; and they do not remain in the same place of their heaven but roll very swiftly into one part after another, so that they do not threaten one and the same part with destruction or consumption by excessive heat; and it was enough to restrain and temper the elements of fire and air, enclosed by waters on both sides. Fifthly and lastly, he perhaps used the Watery heaven as the primum mobile — not so that that water should be a clepsydra measuring universal time by its downward flow, but so that by its perpetual whirling in a circle it might sweep the sphere of the Fixed stars along with it, and, carried round on the poles of the Equator in the space of 24 hours, might revolve that sphere along with itself — yet in such a way that the sphere of the Fixed stars should advance little by little toward the East on the poles of the Ecliptic. I said *perhaps*, because the motion of the Fixed stars toward the West could perhaps be reconciled in another way with their motion toward the East, as we shall say in section 2.

Thus for us the number of the elements and of the heavens, visible and invisible, is preserved, without a superfluous heap of orbs and without any incongruity in the works of God; the authority of the divine scriptures is preserved; the interpretation of the Fathers and Doctors of the Church, agreeing as though in a single council, is preserved; and finally the consensus of the more recent Astronomers is preserved. To my mind these considerations far outweigh the subtleties of certain Peripatetics, and their conjectures, which are topical rather than physical or metaphysical. Therefore the saying of our Oviedus, on page 463 of his *Course of Philosophy*, pleases me greatly: *In a Question whose resolution is destitute of all natural reason* — that is, of valid or forceful reason — *one must take refuge in the authority of the Fathers and Doctors*, etc.

CAPVT VI.

Chapter VI.

An Cælum Sit Generabile & Corruptibile.

Whether the Heaven Is Generable and Corruptible.

I. [Margin: 1. Opinion: for incorruptibility.] The FIRST opinion was, and still is, that the heaven is ingenerable and incorruptible intrinsically and by its own nature. This was held not only by Aristotle (*On the Heavens*, book 1, chapters 3 and 4, and book 2, chapter 1) and by all those Peripatetics who affirmed that the heaven is a certain simple substance — that is, one not composed of matter and form really distinct from each other — and indeed that it is an eternal and necessary being (I have already listed the chief of them, as regards

simplicity, in chapter 5, number 1). It was held also by many of those who said that the heaven consists of matter and form really distinct from each other. Chief among these were St Thomas, part 1, question 66, article 2, and on book 2, distinction 14, question 2; Albert the Great, part 1 *On the Four Coevals*, question 4, article 1; Alensis, part 2 of the *Summa*, question 50; St Bonaventure on book 2, distinction 14, article 1, questions 1 and 2; Pererius, book 2 on Genesis, question 1; Molina, part 1, question 9, article 2, disputation 2; Suarez, disputation 13 of the *Metaphysics*, section 11, from number 13; the Coimbra commentators, book 1 *On the Heavens*, chapter 3, question 1, article 2; Adam Tanner, question 5 *On the Heavens*, assertion 2; Amicus, tractate 5 *On the Heavens*, question 1; Hurtadus, disputation 1 *On the Heavens*, section 5; Arriaga, the single disputation *On the Heavens*, section 3, number 42; Oviedus, the single controversy *On the Heavens*, point 2, number 20; disputation 22 of the *Physics*, Ioannes Poncius [John Punch], question 4, last conclusion; and Tycho, in the letters cited in chapter 5, number 4 — whom, however, Tellez wrongly adduces for the contrary view. Some of these, however, such as St Bonaventure and Molina, grant the visible heaven matter of the same kind as the sublunary, but attribute its incorruptibility to the perfection of the form, or to the incapacity of a natural agent. Some, again, add that it will not be destroyed as to its substance even at the end of the World — so Pererius, the Coimbra commentators, and Tannerus.

[Margin: Arguments for incorruptibility.] Their foundations are these. *First*, the authority of Saints Dionysius, *On the Divine Names*, chapter 4; Gregory of Nyssa, the book *On the Making of Man*, chapter 1; Jerome on chapter 65 of Isaiah; Augustine, *City of God*, book 4, chapter 24; and Gregory the Great, *Moralia*, book 11, chapter 5 — who seem strongly to favour this opinion. *Secondly*, that this grade of incorruptible bodies is required for the perfection of the universe, since such a grade is not otherwise impossible. *Thirdly*, because no trace of substantial generation or corruption appears in the heaven as a whole or in its parts: all the novelties of the heaven — new stars, say, and Comets, and the spots and faculae of the Sun — can be accounted for by mere alteration, and by condensation or local motion, or at any rate by a fresh creation made by God. *Fourthly*, because the Fathers who say that the heavens are corruptible say so because neither the destruction of their substantial form nor even the annihilation of the whole composite is repugnant to them with respect to divine Omnipotence; and in fact the heavens are to be destroyed, or at least greatly changed as regards their accidental qualities.

II. [Margin: 2. Opinion: on the corruptibility of the heaven.] The *Second* opinion was, and still is today, that this visible heaven is corruptible by its nature — indeed, if you speak of our Theologians, that it is to be destroyed. Its ancient authors are reported by Plutarch, *De placitis*, book 2, chapter 4; Theodoret, in the book *On Matter and the World*; St Jerome on Isaiah, chapter 51; and Eusebius, book 15 of the *Preparation for the Gospel*. Thus, besides Heraclitus and Cratylus, who held that earthly and celestial things are in continual flux, those who judged that the heaven would at some time be dissolved were Anaxagoras,

Democritus, Epicurus, Chrysippus, Cleanthes, Posidonius, Antipater, Panetius, and their chief Zeno, and Seneca, a follower of the Stoics. As for what Plutarch says above — *Pythagoras and the Stoics hold that the world was begotten by God and is liable to corruption as far as its own nature goes, since it is sensible and corporeal; yet it will not therefore perish, but will endure for ever, since divine power holds it together; Epicurus holds that it will perish, since it was begotten, like an animal or a plant* — this belongs to the opinion of Pythagoras, not to that of the Stoics, since they thought that the world would at last be burned up in an ecpyrosis, or conflagration. That the Sibyls also sang of this is gathered from book 2 of the *Oracles*, from these verses:

Then a burning, fiery river shall flow from high heaven, and shall consume all places utterly, etc. And the celestial pole, etc.

Plato too, in the *Timaeus*, asserts that the heaven is by its nature dissoluble and perishable, but by the favour of God immune from [?] for the meantime[23]; and Aristotle also attributes this view to him (*On the Heavens* 1, text 102). Cicero held the same (*On the Nature of the Gods*, book 2), as did Lactantius (*On False Religion*, chapter 12) and Macrobius (book 1 on the *Dream of Scipio*). But that the heaven is corruptible, and is in fact to be substantially destroyed, is taught by the Master of the Sentences on book 2, distinction 14, and in the same place by Scotus, question 1, and Carthusianus, question 7; by Catharinus on the Epistle to the Hebrews, chapter 1, and on 2 Peter 3; Vallesius, *De sacra philosophia*, chapter 89; Hieronymus Magius [Girolamo Maggi], book 2 *On the Burning of the World*, chapters 6 and 7; Vielmius, lecture 18 on Genesis; Ascanius Martineng[?]s in the *Glossa magna*, from page 592; Salmeron, volume 1, last prolegomenon, and on 2 Peter 3, disputation 4, and in the same place Cornelius à Lapide and Serrarius; Martinus del Rio on chapter 1 of Genesis; our Molina, *De opere sex dierum*, disputation 3; Cornelius à Lapide both in the places cited and on Isaiah, chapter 34, from page 294; Leo Castrius [León de Castro] on chapter 51 of Isaiah; Emmanuel Sà [Manuel de Sá] in his notes on the 2nd Epistle of St Peter; Fabricius Paulucius on 2 Peter, chapter 3; Marinus Mersennius [Marin Mersenne] on Genesis, page 12, column 2; Io. Bapt. Folengus [Giovanni Battista Folengo] on Psalm 101; Genebrardus on Psalm 101; Martinus Becanus, *On the Work of the Six Days*, from page 403; and Io. Ludovicus de la Cerda [Juan Luis de la Cerda], *Adversaria sacra*, chapter 154. Suarez, too, thinks it probable, volume 2 on part 1, disputation 58, section 2; so Eusebius Nieremberg [Juan Eusebio Nieremberg], book 6 *On the Life of the Stars*, chapter 13; Tannerus in the dissertation *On the Heavens*, question 5, and volume 1 of his theology, disputation 6, question 2, doubt 6; Scheiner in the *Rosa Ursina*, book 4, part 2, chapters 24 and 25; Mastrius and Bellutus, disputation 2 *On the Heavens*, question 3; Kepler, *On the New Star*, chapter 23; Descartes, page 193 of his *Philosophy*; Franciscus Resta, the tractate, and book 1 of the *Meteorologica*, chapter 10; Balthassar Tellez, disputation 40 of the *Physics*, section 1; Fromond[?]s, book 3 of the *Meteorologica*,

[23] the print reads "ab interim interim immune", with "interim" set twice; the noun governed by "ab" is not printed — "interitu", "destruction", is the likely intended word, a conjecture

article 6; and Bullialdus [Ismaël Boulliau], book 1 of the *Astronomy*, chapter 5. Salian, however, although he had championed this opinion in the *Annals*, at the 4th day of the world, number 9, later seemed in the scholia to retract it and return to the Peripatetics. But I had nearly forgotten Lucretius, book 6, who sings thus:

And since I have taught that the temples of the world are mortal, and that the heaven consists of a body that was born, and that whatever things come to pass in it, and will come to pass, must be dissolved, etc.

The foundation of this opinion is threefold: namely the authority of sacred Scripture, the testimonies of the Fathers, and arguments drawn from experience — from the Spots and faculae, which arise and perish near the Sun's disc, as the Telescope bears witness, and from some Comets born and dying above the Moon, whose vicissitudes are explained more connaturally by generation and corruption than by other, more violent modes, or modes that involve miracles.

III. [Margin: 1. Argument, from Holy Scripture.] *First*, then, Psalm 101 says: *In the beginning, O Lord, you founded the earth, and the heavens are the works of your hands: they shall perish, but you remain; and they shall all grow old like a garment, and like a covering you shall change them.* And Job 14: *Man, when he has fallen asleep, shall not rise again until the heaven be worn away; he shall not awake from his sleep.* But it is certain that men will one day rise again; therefore the heaven too will one day be worn away. Isaiah, chapter 24: *All the host of the heavens shall waste away, and the heavens shall be rolled up like a book, and all their host shall fall away*; and chapter 51: *The heavens shall melt away like smoke, and the earth shall be worn out like a garment*; and chapter 65: *For behold, I create new heavens and a new earth.* And Matthew 24: *Heaven and earth shall pass away.* And 2 Peter, chapter 3: *But the day of the Lord will come like a thief, in which the heavens will pass away with great violence, and the elements will be dissolved with heat, and the earth and the works that are in it will be burned up. Since, then, all these things are to be dissolved*, etc.; and in the same place: *the heavens, being on fire, will be dissolved, and the elements will melt with the heat of fire; but we look for new heavens and a new earth according to his promises.* And earlier in the same place St Peter had said: *But the heavens are laid up, reserved for fire.* These authorities may not be interpreted, without necessity, by destroying or abandoning the literal sense. And it was soundly said by our Maldonatus, on the words *and the stars shall fall from heaven*: *I judge that Christ, who affirms it, is to be believed rather than Aristotle, who denies that it can happen*; and there he also holds, with Chrysostom and Euthymius, that the stars will truly fall.

[Margin: 2. Argument, from the Authority of the Fathers.] *Secondly*, several Fathers teach that the waters are above the heavens for this reason: to protect them meanwhile from the excessive heat of the stars; and they assert that the heavens are watery or fiery, as we have already shown in chapter 2, questions 1 and 3, and in chapter 3, conclusion 4, argument 5. Therefore, just as the elements are corruptible of themselves, so too are the heavens. Indeed, they teach in express words, which no evasion can escape, that the heavens are in fact

to be dissolved and, their former form being destroyed, transformed into a better state — as anyone may see who reads their words in Ascanius Martinengus, *Glossa magna*, and in Scheiner, book 4 of the *Rosa Ursina*, part 2, chapter 24. So, first of all, St Justin, *Responses to the Orthodox*, questions 93, 94 and 95; St Basil, homilies 1 and 3 on Genesis, and 6 of the *Hexaemeron*; St Ambrose, *Hexaemeron*, book 1, chapter 6; St Chrysostom, homily 10 to the people of Antioch, homily 23 on chapter 9 of Matthew, and homily 14 on chapter 8 of the Epistle to the Romans, and in the same place Theodoret; Oecumenius, in the collectanea on chapter 3 of the 2nd Epistle of Peter; St Damascene, book 2 *On the Faith*, chapter 6; Gennadius, the book *On Ecclesiastical Dogmas*, chapter 7; St Jerome on chapter 51 of Isaiah; St Hilary on Psalms 122 and 148; St Epiphanius, book 2 *Against Heresies*; St Irenaeus, book 4 *Against Heresies*, chapter 6; St Cyril of Alexandria, book 4 on Isaiah, chapter 51; Andreas of Caesarea, sermon 22 on the Apocalypse; Zacharias Scholasticus, bishop of Mytilene, in the disputation *On the Making of the World*; and Caesarius, *Dialogues*, question 71.

[Margin: 3. Argument, from reason and examples.] *Thirdly*, that the Spots and Faculae of the Sun are newly generated and perish is proved by the arguments already indicated in book 3, chapter 3, and by those to be adduced from Scheiner in book 9, section 4, chapter 12, numbers 19 and 20; and the same is proved of the Comets that are above the Moon, of which enough was said in book 8, section 1, chapter 6, as also of the new stars in section 2, chapter 17. Granted [?] that Tannerus (dissertation *On the Heavens*, question 7, and volume 1 of his theology, disputation 6, question 3, doubt 3) contends either that the observations of the Mathematicians who assert these novelties are uncertain, or that these things are done by God in a supernatural manner, as portents, or that the spots are carried round the Sun on special Epicycles and that Comets and new stars descend towards us in the course of time — of these and the other modes devised to explain these Phenomena enough has been said by us, in the places indicated a little earlier. Let this, then, be the

CONCLVSIO.

Conclusion.

It is more probable that the visible heavens are corruptible by their nature and intrinsically, although they are incorruptible per accidens and extrinsically.

IV. The first part of the Conclusion is proved from what was said in chapter 5, number 10, for conclusion 4. For by the very fact that we proved that the heaven of the Fixed stars is watery and that of the Planets fiery, and showed this to be the more likely view, it follows that these heavens are intrinsically and by their nature capable of generation and corruption; and that their matter is not so bound to the celestial form that, if a natural agent apt to introduce another form were given, that matter would not be positively apt to receive it. Yet — whether on account of their distance, or of their huge bulk, or of the remarkable tempering of the secondary qualities with the primary that God has put into the heaven — there is no created natural agent that could transform the heavens

substantially; and for that reason I said that they are incorruptible per accidens, in the way that neither the whole earth nor the whole air is transmutable as to the whole or the greatest part of itself. The Conclusion is confirmed, moreover, because the new Phenomena of the stars and of the Comets, and those of the Solar spots, and the dissolution and renewal of the heavens at the end of the world, are to be explained preferably without a miracle, or at least with a lesser miracle, and in a more physical manner, similar to that of the other natural bodies that come to be anew. And this is achieved if it is admitted that the heaven is now subject to generation and corruption in some small part of itself, and that at the end of the world Fire is to be taken up by God as the instrument for the substantial renewal of the heavens. Nor do I care, or have I leisure, to linger longer over a controversy of this kind, which has neither evident reasons nor authorities that cannot be explained away.

[Margin: The incorruptibility of the Empyrean.] I said in the Conclusion "the visible heavens"; for that the Empyrean heaven is incorruptible is sufficiently proved from the Fathers' manner of speaking, on which see chapter 1, question 6, where that heaven and its conditions are treated at length. And this is the body that was required for the perfection of the Universe — but for that state and order of things in which our bodies too will have incorruptibility and eternal soundness.

[Margin: The destruction of the heavens at the end of the World.] How the heavens are to be dissolved at the end of the world is treated learnedly, above all, by Pererius, book 2 on Genesis, questions 1, 2 and 6; Tannerus, *On the Heavens*, question 11, and volume 1 of his theology, disputation 6, question 4, doubt 5; Salmeron on 2 Peter 3; and others cited by them.

CAPVT VII.

Chapter VII.

An Cæli Solidi ſint, an verò Fluidi omnes vel aliqui.

Whether the Heavens Are Solid, or Rather All or Some of Them Fluid.

1. THERE is no doubt that the heaven of the Planets is solid, if solidity is taken broadly for the threefold dimension of a body having length, breadth and depth — the sense in which Philo (book 1 *On the Making of the World*), Origen (homily 1 on Genesis) and St Basil (homily 3 of the *Hexaemeron*) said that every body is solid; I gave their words in chapter 2, question 2. Nor is it disputed among others whether the heaven of the Fixed stars has some depth or height: Philo, in the book *On Dreams*, is the only one I have found calling this into doubt, in these words: *Does that outermost sphere of the Fixed stars have solidity, or only a surface without height, like figures painted on a plane?* For Physicists and Astronomers commonly attribute to the Fixed stars some corpulence and bulk, like that of globes or quasi-globes, and so attribute to the heaven in which they are fixed some thickness or depth as well, which Philo, as I said, calls solidity. The controversy, therefore, concerns solidity taken strictly: solidity which,

besides the threefold dimension, has joined to it a hardness opposed to softness — the sense in which we say that marble is solid, and metals so long as they do not melt, and ice itself before it is dissolved. With these points noted in advance:

II. [Margin: 1. Opinion: on the Solidity of all the heavens.] The *First* opinion was, and endures to this day, that all the starry heavens are Solid. It was held by Aristotle, *On the Heavens*, book 2, from text 43 to 52, where he contends that the stars do not move in the heaven as fish do in the sea — that is, they do not move of themselves — but with the motion of the orbs, some of which, the rotating ones [voluentes], he devised and named with Eudoxus and Calippus, and others, the Revolving ones [Reuoluentes], from his own ingenuity (*Metaphysics* 12); by Plato in the *Timaeus*, though on the interpretation of Eusebius, book 1 of the *Preparation for the Gospel*, chapter 16; and by Anaximander, as Plutarch reports, book 2 *De placitis philosophorum*, chapter 16. It was held by Dionysius Carthusianus on book 2, distinction 14, question 3, who says: *By the inviolable authority of canonical scripture, the heavens are most solid, as if cast of bronze.* The Master indicates the same on book 2, distinction 14; and it is taught by St Thomas on book 2, distinction 14, question 1, and part 1, question 68, article 2, and by many Scholastics, St Bonaventure excepted; and also by Gulielmus Parisiensis, part 1 *On the Universe*, tractate 3; Lippomanus in the *Catena* on chapter 1 of Genesis; Fracastoro in the *Homocentrica*; Alfraganus [al-Farghānī], *dist.* 14 and 17; Sacrobosco and Clavius on the *Sphere*, chapter 4; Purbachius [Georg von Peuerbach] in the *Theoricae*, and his followers; Fernelius [Jean Fernel] in the *Cosmotheoria*; Vielmius on Genesis, lecture 14; Pererius, book 2 on Genesis, question 9; Martinus Del Rio on chapter 1 of Genesis, number 36; the Coimbra commentators on book 2 *On the Heavens*, chapter 8, question 1; Martinengus in the *Glossa magna*, page 1018 in my copy; Suarez, book 1 *De opere sex dierum*, chapter 5; Salian in the *Ecclesiastical Annals of the Old Testament*, at the 2nd day of the World; Adam Tanner in the dissertation *On the Heavens*, question 6, assertions 1 and 2, and volume 1 of his theology, disputation 6, question 3, doubt 2, likewise assertions 1 and 2 — although Tellez did not hesitate, wrongly and ill-advisedly, to adduce him for the opposite view; Amicus, tractate 5 *On the Heavens*, question 5, article 3; Io. Poncius, disputation 22 of the *Physics*, question 5; and Aversa, question 33, section 6. And although we ourselves think otherwise about Copernicus, as will appear from what is to be said in section 3, chapter 1, number 14, Tycho nevertheless attributes this very reality and distinctness of the orbs to Copernicus, though with hesitation, in volume 1 of the *Progymnasmata*, page 439, and to Ibn al-Haytham and Witelo in the *Letters*, page 61. The foundations of this opinion will be refuted a little below.

Secunda opinio de Fluiditate Cælorum Vniuerſaliter aut indefinitè.

The Second Opinion: on the Fluidity of the Heavens, Universally or Indefinitely.

The SECOND opinion affirms that all the heavens are fluid, either expressly or implicitly, inasmuch as it asserts indefinitely that they are fluid, that is, freely

permeable by the stars. [Margin: Most of the ancients.] So held certain of the ancients reported by Aristotle, *On the Heavens* 2, texts 45 and 56; to them are referred all who said that the stars are fed by moisture — namely Homer, Anacreon, Virgil, Lucretius, Pliny, Manilius, Seneca, Metrodorus and others adduced by our Lorinus [Jean Lorin] on 2 Peter 3. [Margin: Cicero.] Cicero held the same, together with those learned in physical matters, when he said in book 2 *On the Nature of the Gods*: *The stars, moreover, occupy the ethereal region; and since it is most subtle, and is always in motion and in vigour*; and soon after: *Nor do they have ethereal courses, nor do they inhere in the heaven, as most say who are ignorant of physical reasoning. For the nature of the aether is not such that it could embrace the stars and whirl them round by its own force: the aether, thin and transparent and suffused with an even heat, does not seem apt enough to hold the stars. The fixed stars, therefore, have their own sphere, separated and free from any conjunction with the aether.* [Margin: Pliny.] Pliny seems to have been of the same opinion, book 2, chapter 5, where by the name *spiritus* he understands both air and aether; in which sense he says in chapter 6: *Between earth and heaven, hanging in the same spiritus and separated by fixed intervals, are the seven stars which from their motion we call wandering.* [Margin: Vitruvius.] Vitruvius too, book 9, chapter 4, indicated clearly enough that at least that part of the heaven through which the Planets travel is free and fluid, when he said that Mercury and Venus go round the Sun, crowning it as their very centre, stand still and retrograde, and that the seven planets make their journeys as if through channels, against the diurnal motion. [Margin: Hyginus.] Hyginus likewise, in book 1 of the *Poetica Astronomica*, listing the sum of what he had written, says: *Next we have set out whether the Sun, being fixed, was turned with the World, or moved of itself; and, if it moves of itself and goes against the risings of the twelve signs, why it rises and sets with the World.* Then in book 4 he tries to prove that the Planets are not moved as if fixed in the heaven — by an argument hardly necessary, but one that nonetheless reveals his opinion — saying: *But, as I said before, we shall now speak straightway of the course of the Sun. For it is necessary either that the Sun moves of itself, or that it turns with the world while remaining in one place. If it remained, it would necessarily set and rise in the same place in which it had risen the day before, just as the signs rise and set in the same place, etc. If, therefore, it rises and sets in different places, it is necessary that it moves and does not stand still* — that is, does not move with the World, but by itself and freely. [Margin: Germanicus.] Germanicus, the translator of Aratus, agrees with him, saying: *It is established that the Sun moves by itself, not that it is turned with the World.* [Margin: Manilius.] And Manilius indicates it in book 1 of the *Astronomica*, when he says of the motions of the stars: *All things are passable*; and again: *Since the Moon and the stars fly through the voids of the world.* [Margin: Seneca.] Seneca teaches most plainly that Comets and stars travel freely through the liquid aether, and rejects the opinion of Artemidorus, which ascribes hardness to the heaven, as may be seen in book 7 of the *Natural Questions*, chapters 12, 13, 14, 15, 23 and 24. [Margin: Ptolemy.] Ptolemy, moreover, is counted in

this very class by St Thomas, part 1, question 70, article 1, in these words: *It must be said that according to Ptolemy the luminaries are not fixed in the spheres, but have a motion separate from the motion of the spheres.* Here the holy Doctor leaves everyone free to hold what he will about the hardness and liquidity of the heaven. So Dionysius Carthusianus, on chapter 1 of Genesis, article 10, on the words *Let there be Lights in the firmament*, says: *Plato in the Timaeus says that the stars are not fixed in the firmament, but travel and lead a dance in it, and in this Ptolemy followed Plato; hence they say that it is not the heaven but the stars of the heaven that are moved and carried round.* Likewise Vielmius, *On the Six Days*, lecture 20: *It is certain that Ptolemy, the prince of Astronomers, affirmed that the Eccentrics and Epicycles by no means really exist.* And Cornelius à Lapide, on the 2nd Epistle of St Peter, chapter 3, and Scheiner, book 4 of the *Rosa Ursina*, part 2, chapter 29, hold the same of Ptolemy, as favouring the liquidity of the heaven. Scheiner, about to bring Ptolemy himself forward, says aptly: *Let Ptolemy come forward and speak for himself; for he is 1498 years old, and, grey with much wisdom, he lives still — lives, I say —* because Ptolemy himself says in the preface of the *Almagest*: *A man's learning is the companion of his intellect and his intercessor among men, and he who gave life to knowledge did not die.* Now Ptolemy, in book 13 of the *Great Composition*, chapter 2, seeing that the paths of the Planets would seem difficult to many, says: *Those are divine bodies, which suffer no hindrances either from others or from themselves*; and soon after: *Especially since their nature has no power whatever of resisting, but accommodates itself with the greatest proportion and ease, and, as is according to nature, makes room for their motions by yielding place, even if these are found to be contrary to one another, so that all flows can pass through and shine through any bodies whatever.* Raffaele Aversa, volume 2 of his *Philosophy*, question 33, section 1, affirms, however, that Ptolemy held that the heaven consists of all the elements.

[Margin: Rabbis.] The fluidity of the heavens, moreover, is asserted expressly by many Rabbis, as reported by Iacobus Naclantus [Giacomo Nacchianti] in the *Medulla*; [Margin: Gilbert.] by William Gilbert, book 6 *On the Magnet*, chapter 3; [Margin: Neander.] Michael Neander, *Elementa astronomica*, chapter 4; [Margin: Peucer.] Caspar Peucer, in Tycho's *Letters*, page 157, and in the same, Christoph Rothmann, page 149; [Margin: Tycho.] Tycho himself, as we shall see presently, in the *Letters*, page 149, and in volume 1 of the *Progymnasmata*, page 794, and volume 2, page 268 — whose words we shall report under the 5th opinion, in which some place him; [Margin: Longomontanus.] Longomontanus, chapter 5 *On Comets*, and in the *Astronomia Danica*, book 1 of the *Theorica*, chapter 1, folio 161, and chapter 4, folio 220, teaching that the Fixed stars too, and not only the Planets, are balanced in the most limpid aether no differently from the Earth in the air, and that they are not moved, lest they be drawn apart from one another in the expansive stereoma, or firmament — which would not have to be feared if they were fixed in a solid sphere; [Margin: Kepler.] Kepler, in the *Mars*, chapter 4, and in the *Epitome of Copernican Astronomy*, pages 53, 142 and 495, saying that the single heaven of

all the stars consists of a most thin ethereal breeze; [Margin: Galileo.] Galileo in the *Sidereus Nuncius*, in the *History of the Spots*, and in Dialogues 1 and 2 *On the System of the World*; [Margin: Scheiner.] Christoph Scheiner, book 4 of the *Rosa Ursina*, part 2, from chapter 26 to 30, and, cited by him, [Margin: Mästlin.] [Margin: Gemma.] [Margin: Vuitichius.] [Margin: Raymarus.] Cornelius Gemma, Vuitichius [Paul Wittich], Mästlin, Nicolaus Raymarus [Nicolaus Reimers Ursus], and Orazio Grassi, who adds on page 765, [Margin: The Chinese Mathematicians.] from the letters of our Fathers among the Chinese, that the opinion of the hardness and multiplicity of the Planetary heavens is held there to be foreign, new and vain, and that they will not let themselves be moved from the opposite view. [Margin: Ciccus.] Likewise Mersennius on Genesis, pages 836 and 843; and Ciccus Esculanus [Cecco d'Ascoli] on the *Sphere*, saying that the orbs of the Planets are neither continuous nor contiguous, but stand in a middle way, and that between them there is a body that admits compression. [Margin: Michael Scotus.] So too Michael Scotus [Michael Scot], in the *Questions on the Sphere*, page 105, says that "solid" is said in three ways: in one, of what is hard, like earth; in the second, of what is continuous, as are the remaining elements and the supercelestial bodies; in the third, of what has the threefold dimension. [Margin: Origanus.] [Margin: Mariana.] [Margin: Celada.] [Margin: Renatus.] [Margin: Aversa.] So also Origanus in the preface to the *Ephemerides*; Mariana [Juan de Mariana] on Genesis, chapter 1, verse 12; Celada [Diego de Celada] in the same place; Descartes, part 3 of the *Philosophy*, number 24; Raffaele Aversa, volume 2, question 34; [Margin: Bullialdus.] [Margin: Tellez.] Bullialdus, book 1 of the *Astronomia Philolaica*, chapters 2 and 4; Tellez, disputation 40 of the *Physics*, section 1, numbers 16 and 21, and disputation 44, section 3, number 5; the *Aristarchus* published at Paris, page 23; [Margin: Hevelius.] [Margin: Snellius.] [Margin: Stevinus.] [Margin: Gassendus.] [Margin: Crugerus.] [Margin: Eichstadius.] [Margin: Linemannus.] Io. Hevelius [Johannes Hevelius], chapter 7 of the *Selenographia*, and, cited by him, Snel, Stevin, Gassendi, Crugerus [Peter Crüger], Eichstadius [Lorenz Eichstädt] and Linemannus [Albert Linemann]; [Margin: Pena.] likewise Ioannes Pena in the preface to the *Optics*; [Margin: Cysatus.] and Io. Baptista Cysatus, *On the Comet of the year 1618*, affirming that Comets pursue their courses in a most limpid expanse of aether. [Margin: The Professors of Parma.] [Margin: Bellarmine.] This same opinion was first defended by our Professors in the theses published at Parma in the year 1613, theses 742, 743 and 783; and Federico Cesi, in a letter to Io. Faber [Johann Faber], cited by Scheiner in the *Rosa Ursina*, book 4, part 2, chapter 27, testifies that Bellarmine was of the same opinion.

[Margin: 3. Opinion, positing the same heaven partly solid, partly fluid.] The *Third* Opinion divides the same heaven into a solid part and a fluid part, positing channels in every Planetary heaven, full of air or of a subtle and thin breeze, through which the Planets can travel — as Hurtadus posits, disputation 2 *On the Heavens*, section 1, though disputation 1, section 5, paragraph 29, should

be consulted. But St Bonaventure, on book 2, distinction 14, part 2, article 1, question 1, teaches that the Luminaries are placed in several orbs, but orbs that are continuous, subtle and suited to motion, and that the diversity of motions in them does not remove the continuity of those orbs, just as it does not remove it in water and in air. From these words Tannerus and Amicus gather that he recognises the Planetary heavens as being in part soft and fluid.

[Margin: 4. Opinion: on the outermost heavens alone being [?].] The *Fourth* Opinion is that of our Father Niccolò Cabeo, on book 1 of the *Meteorologica*, text 37, question 6, and on book 2, text 11, question 4, where he thinks it more probable that the heaven of the Fixed stars and the heaven of the Moon are solid, so that the starry heaven is thus enclosed on either side by a stable boundary; and because we have no argument for fluidity in these heavens from the celestial phenomena, such as we have for the fluidity of the other heavens enclosed within them. He is moved to suspect this chiefly lest the spirits of the earth and the sea, and the volatile salts, flying upward without limit, should be consumed and never return to ferment the earth; rather, they are kept by the hardness of the lunar heaven from travelling further upward, and are driven back down.

[Margin: 5. Opinion, positing the heaven of the Fixed stars solid, that of the Planets fluid.] The *Fifth* opinion, and now the most celebrated, is that the heaven of the Fixed stars is solid, and that the non-wandering stars are set in it like nails or knots, while the heavens of all the Planets are fluid. The first to hand down this distinction, so far as I know, was Empedocles; for Plutarch says in book 2 *On the Opinions* [*de Placitis*], chapter 13: *Empedocles holds that the non-wandering stars are bound to the crystal, but the wandering ones loose*; and Anaximenes seems to agree with him, for Plutarch goes on thus in chapter 14: *The Stoics hold the stars to be globular, like the world and the Sun and the Moon; Cleanthes, cone-shaped; Anaximenes, fastened like nails to something crystalline. There are some who think them fiery plates, like painted ornaments.* There he seems to report opinions about the stars as distinct from the Sun, the Moon and the other wanderers. Plato, too, called the non-wandering stars *Haerentes* ("the clinging ones"), as Plutarch has it in book 2 *On the Opinions*, chapter 15. Therefore what Carthusianus says on Genesis, article 10 — *Plato in the Timaeus said that the stars are not fixed in the firmament, but travel and lead dances in it* — is to be understood of the Planets. After these, Richardus Victorinus, in book 2 of the *Exceptiones*, chapter 7, said expressly: *The lights of the stars are shown to be fixed in the firmament, except the seven Planets*; and St Anselm, in book 1 of *De imagine Mundi*, chapter 24, says that the aether in which the seven Planets move is as much thinner and subtler than air as air is thinner than water, and that in it the seven stars move about freely, although they are swept round by the Firmament, like a fly on a mill-wheel, etc. Junilius too, on the *Hexaemeron*, distinguishes the Firmament, in which the Fixed stars are, from the aether, which he declares to be like pure air; he says that the aether reaches up to the stars of the firmament, and that in it the seven wandering stars are carried about

freely. His words, like Anselm's, I reported in chapter 2, question 2, at the end of number 4.

Among the more recent writers the same distinction is indicated by Philalthaeus on book 2 *On the Heavens*, text 46; Io. Antonius Delphinus, *De caelestibus globis ac motibus*, page 80; and Antonius Mizaldus [Antoine Mizauld] in the *Planetologia*. Tycho too is cited for it by some. But he calls the heaven liquid indefinitely, in his letter to Rothmann of the year 1587, January 20, page 60, and in that of the year 1588, August 17, page 106, and in others, pages 109, 120, 137 and 152. From these it is clear that Rothmann too was of the same opinion — namely, that the heaven in which the Planets move is most liquid and not at all hard — granted that Rothmann holds it to be of air, while Tycho holds it to be of aether and of a nature different from the elementary one. Tycho drives home the same opinion in volume 1 of the *Progymnasmata*, pages 92 and 641, and in all these places he rejects real orbs. But in volume 1 of the *Progymnasmata*, page 794, treating of the matter from which the new star of the year 1572 was compacted, and which he had often said was in the eighth sphere, he says: *For even though the whole heaven is something most thin, and everywhere open to the motion of the stars without any obstacle, it is nevertheless by no means wholly incorporeal (otherwise it would also be infinite and without place). The very matter of the heaven, therefore, most subtle as it is and open to our sight and to the powers of the Planets, could nevertheless, condensed and compacted into one globe and lit by a light if not its own then at least the Sun's, form this star*; and soon after: *and although in the whole vastness of the celestial World there is, in my judgement, matter abundantly available for the formation of any adventitious star, yet nowhere more copiously and fully than near the Milky Way, etc.* Although, then, he once said that the heaven is open to the motions of the Planets, yet because he said universally that it is open to the motions of the Stars, and called the whole heaven such — and pointedly that part in which the stars of the Milky Way are — he acknowledged the heaven of the Fixed stars too to be liquid, and is therefore to be counted among the authors of the second opinion.

In this 5th opinion, however, were Tassonus, book 2, question 3; Blancanus [Giuseppe Biancani] in the *Sphaera*, who assigns spiral and free motions to the Planets, but to the Fixed stars a motion according to the motion of the Firmament; Fortunio Liceti, book 5 *De novis astris*, chapter 50; Io. Camillus Gloriosus [Giovanni Camillo Glorioso], book 4 *De Cometis*; Froidmont, book 3 of the *Meteorologica*, chapter 1; Paulus Aresius [Paolo Aresi], book 1 *On Generation*, question 23, section 8; Hugo Sempillius [Hugh Sempill], book 10 *De mathematicis disciplinis*, chapter 1; Franciscus Oviedus, the single controversy *On the Heavens*, point 3, paragraph 4; Rodericus Arriaga, the single disputation *On the Heavens*, number 41; and Io. Bapt. Zupus [Giovanni Battista Zupi], as reported by Amicus, tractate 5 *On the Heavens*, question 5, article 2; and Mastrius and Bellutus think it very probable, disputation 2 *On the Heavens*, question 1, number 38. All these, I say, assert that the heavens of the Planets are fluid; as for the heaven of the Fixed stars, they either affirm that it is solid, or bring only

arguments for fluidity that suit the Planetary heavens alone — which holds also of many authors adduced for the 2nd opinion. It must be noted, however, that most followers of the Copernican sect assign no motion to the Fixed stars; and because they think the Earth, as a Planet in the heaven, is moved around the Sun, the centre of the world, they accordingly hold the whole Planetary system to be thin and permeable — which Aristarchus and certain Pythagoreans also posited long ago, for the same reason. [Margin: Ptolem[?], asserter of fluidity [?].] That Ptolemy, however, is to be counted in this fifth class we shall show in section 2, chapter 2, number 3; it is also clear enough from book 13 of the *Almagest*, chapter 2, and St Thomas teaches it expressly, part 1, question 70, article 1, reply to 3, as does Carthusianus on Genesis, article 12.

EXAMINANTUR ARGUMENTA PRO SOLIDITATE OMNIUM, AUT ALIQUORUM CÆLORUM; & SOLUTIONES EORUM.

The Arguments for the Solidity of All, or of Some, of the Heavens Are Examined, with Their Solutions.

III. [Margin: 1. Argument, from Holy Scripture.] The *first* argument is drawn from Holy Scripture. For the heaven, in Genesis 1, is called the Firmament, from the word *Raquiah*, which signifies a firmament — or an expansion indeed, or extension, but with firmness and solidity; and therefore the Seventy Interpreters rightly called it στερέωμα [Greek: stereōma, "firmament"], that is, something solid, as I taught at greater length in chapter 2 from number 2. There I also taught that the saying of Elihu in Job 37 — *You perhaps made the heavens, which are most solid, as if cast of bronze* — has great authority, because he is not rebuked for it by the Lord, and other sayings of Job's friends were adduced by the Apostles to confirm what they said. Reread what is said there [?][24]. Moreover, Job 14 says: *Until the heaven be worn away*; Isaiah 51: *The heavens shall melt like smoke*; and Hebrews 4: *Who has penetrated the heavens*. But what is worn away, melts and is penetrated is presupposed to be solid.

[Margin: 1. Response.] It can be answered, however, that the name *Raquiah*, according to not a few who are skilled in the Hebrew language, sometimes signifies mere expansion; and that some Fathers and interpreters understood by the name Firmament not something hard, but a stable, durable and impassable boundary between the upper and the lower waters, as I taught in chapter 2, number 2 and number 5, confirming it by the authority of Saints Basil, Nyssenus and Augustine, and likewise of Albert the Great and Tostatus. And it can be answered that the words of Elihu are not those of the canonical writer himself, since many of his sayings are rebuked by the Lord. For when Elihu had spoken from chapter 32 to 37 inclusive, it is said immediately in chapter 38: *Then the Lord, answering Job out of the whirlwind, said: Who is this that wraps up sentences in unskilful words?* Here the Lord, although he is speaking to Job himself, nevertheless pointed at Elihu and at his many sayings spoken unskilfully, even if mixed with true opinions. Nor is that saying of Elihu found confirmed

[24]the print reads "di-/cat", not "dicta"; the sense "what is said" is kept, the construal unsettled

by any canonical writer; Carthusianus, therefore, on book 2, distinction 14, question 3, wrongly called it an inviolable authority of canonical Scripture. That particular rebuke of the Lord against the sayings of Elihu suffices, granted that in chapter 42 he was not rebuked again, but only Job's three earlier friends, namely Eliphaz, Bildad and Zophar, in these words: *And after the Lord had spoken these words to Job, he said to Eliphaz the Temanite: My wrath is kindled against you and against your two friends, because you have not spoken rightly before me, as my servant Job has.* Indeed, it suffices that those words were not uttered in the person of the canonical writer himself, nor approved by any other canonical writer, for them to be set aside as outside the canon of infallible authority. By the verbs *to melt* like smoke and *to be worn away* is signified the corruption of the original form, which will vanish and be consumed at the end of the World. Nor indeed do solid things alone melt or suffer wearing, since wax, oil and clouds melt, and air itself and water give out a sound when friction is made by the winds. Finally, impenetrability, of which the physicists speak, belongs to fluid bodies too. Hence, if Christ penetrated the heavens using the gift of a glorified body, it was a great miracle whether the heavens he penetrated were fluid or solid; but a greater one, without doubt, if an- y heaven too is hard — and it is enough that the heaven of the Fixed stars is of that kind. Therefore it is not necessarily inferred, either from these places of Holy Scripture, which are the principal ones, or much less from others, that all the heavens are solid.

IV. [Margin: 2. Argument: the authority of the Fathers.] The *second* argument is drawn from the authority of many Fathers and Doctors of the Church, who assert in the most explicit words that the Firmament in the midst of the waters was made by God in such a way that it grew solid out of waters consolidated in the manner of ice, or of crystalline stone, or of an eggshell, or of a vault and a wall, as is evident from their words faithfully recited in chapter 2 from number 3. And these are not only Josephus the Hebrew, but Pope Clement, speaking according to the mind of St Peter; Tertullian, Caesarius, Jerome, Chrysostom, Acacius, Severianus, Claudius Marius Victor, Gennadius, Theodoret, Junilius, Procopius, Olympiodorus, Strabus, Anselm of Canterbury, Anselm of Laon, the author of the interlinear Gloss, Petrus Comestor, the Master of the Sentences, Hugo Carensis, Carthusianus — how many men, I ask, and of what quality! Nor does St Augustine, reporting this opinion in book 2 *De Genesi ad litteram*, chapter 1, dare to condemn it.

[Margin: Response.] The response, however, is that many other Fathers and Doctors of the Church, adduced by us in chapter 2, question 2, stand for the fluidity of the heaven, as we made plain from their words reported there. One of two things must therefore be concluded: either one is free to follow whichever opinion one likes, or rather the Fathers are to be reconciled so that the former are understood of one heaven only, namely the eighth sphere, and the latter of the heaven of the Planets — as we have already done in chapter 3, conclusion 4, where the foundations of this distinction were adduced.

V. [Margin: 3. Argument, of Aristotle, and Response.] The *third* argument is Aristotle's, book 2 *On the Heavens*, chapter 7, where he says that it is consonant with reason that the heaven be of the same body as the star, and that every star is solid; therefore the body of the heaven from which it is made is solid too. But granted that the heaven and the Star that is in it were conceded to be of the same matter, it is nevertheless denied that they have the same conditions; otherwise, since a star is luminous and opaque, the whole heaven too would have to be luminous and opaque.

VI. [Margin: 4. Argument, of the Coimbra commentators.] The *fourth* argument. If the heaven in which the stars move were fluid, and neither a vacuum nor the interpenetration of bodies is admitted, it would follow that, at the motion of a star, either the whole heaven would fluctuate, or the part of the heaven pushed by the star would be condensed and the part left behind by the star rarefied. But condensation and rarefaction are incompatible with the heaven, and are a sign of corruptibility. The same holds of that fluid body with which the channels would be filled that some admit in that portion of the heaven through which the stars move.

[Margin: 1. Response, admitting the interpenetration of celestial bodies.] Some would answer that in luminous and celestial bodies mutual penetration can be admitted, whether they are fluid or not. Ioannes Provenzalis admits this, quodlibet 3, question 7; Poncius does not refuse it, disputation 22 of the *Physics*, numbers 52 and 55; nor does Amicus, article 5, number 25; nor do certain Mathematicians cited by St Bonaventure on book 2, distinction 14, part 2, article 1, question 2, who says: *Others say that that body is not cut, and that the Planets pass through it; for the body of light can be together with another body*; and cited by Albert the Great, part 1 of the *Summa*, question 4, article 19, where he says: *Certain ancients said that the Eccentrics and the stars pass through the body which is between the spheres, and yet do not divide it; and this happens because of the formality of those bodies, just as light too passes through the air.* And not a few of the ancients thought that light is a corporeal substance, which nevertheless penetrates diaphanous bodies. [Margin: 2. and 3. Response.] Others, again, could respond that that whole tract of the heaven, or Zone, in which the path of the planet lies, fluctuates. Others will concede rarefaction and condensation in the heaven, and will deny that this is a property belonging to corruptible body alone: for granted that the kind which arises from heating and cooling may seem to be such, yet the kind which comes from mere local motion is common to corruptible and incorruptible body, since density of itself includes nothing but a multitude of parts in the same space, and rarity a fewness of them. [Margin: 4. Response.] Others, finally, granting but not conceding this sign of corruptibility, will deny that the starry heaven is an incorruptible body, according to what was said in chapter 6, number 4.

VII. [Margin: 5. Argument, of Tannerus.] The *fifth* argument is drawn from sound. For it could hardly be avoided, says Tannerus, that a huge sound would be raised by the stars, if such vast bodies broke through a liquid body by

collision at so incredible a speed; for it is established that our air hisses horribly when stones are hurled by the whirling of a sling, and that when lashed by thongs swiftly bent this way and that it resounds. [Margin: 1. Response.] Tycho would answer this argument, in the *Letters*, page 106, that if the celestial orbs were solid, then whether they collided with one another by immediate friction or air were enclosed between them, a huge sound would be produced by the most rapid motion of the stars, one that would strike our hearing too. [Margin: 2. Response.] But Rothmann would answer better, in the same letters, page 121, by denying that the sound, if there were one, would reach our ears, both because of the rarity of the ethereal breeze and because of the huge distance. For he had been, he says, in a place five miles distant from another place in which a most violent wind had overturned buildings and trees, and yet he had not heard the noise; whereas the air near us, because of the watery thickness mixed into it and because of its nearness, makes a sound perceptible to us. And indeed, which of us perceives the crash and roar that accompany lightning from a distance of 10 or 20 miles? Oviedus adds that, just as no sound is made in water by the motion of fish, because water is not thought a medium suited to the species of sound, so neither are the heavens suited to it. Finally, the asserters of solid orbs must themselves answer why fire or air does not give out a perceptible sound from the revolution of the lunar heaven.

VIII. [Margin: 6. Argument, of Aristotle and Pererius.] The *sixth* argument, indicated by Aristotle and driven home by Pererius, is taken from the multiplicity of motions. For it is impossible for the same body to be moved with several motions, and contrary ones at that — as the Planets, and indeed the Fixed stars too, are established to be moved — unless they are moved by one motion of their own in one direction, and with the rest are moved according to the motion of a solid body to which they are fixed or on which they sit. [Margin: Response.] The answer will be to deny the antecedent: for this can happen through a spiral or quasi-spiral motion, in the way indicated elsewhere, book 7, section 1, last chapter, and to be expounded below in this book, in section two. Moreover, even if another body were required for this, it would not necessarily be solid; for fish too, carried downstream by a rapid river, can nevertheless strive upward toward the river's source. Clavius proposes this argument in another way, on chapter 4 of the *Sphere*, page 449. He says that if the planets were moved like fish and birds in a fluid, their motion would be free and too wandering, and so there would be no certain science of their motions — as though they could not be moved by an Intelligence in a fluid while the laws of motion are still observed.

IX. [Margin: 7. Argument, of Tannerus and Poncius.] The *seventh* argument, which Tannerus and Poncius use, is of this kind. It is impossible, or too difficult, for the Intelligences to move the stars with such speed and with so perpetual and constant a uniformity except by means of solid orbs; otherwise, since they cannot move bodies distant from themselves, they would have to be moved together with the stars at equal speed. But this seems absurd. [Margin:

Response.] The answer is to deny the major and the minor. For it is not incompatible that an Intelligence, remaining in a single place, should impress on the star such and so great a motion that it lasts in its vigour and intensity until the star revolves back to the same place, where it receives a new impetus from the Intelligence. Nor, likewise, is it incompatible that the Intelligences be moved together with the stars; for there is no danger at all that they should either tire or at length disdain to serve their Creator in this ministry. In which of the two ways they move the Stars is to be investigated in the following section.

X. [Margin: 8. Argument, of Tannerus.] The *eighth* argument. If solid orbs are not granted, it will be necessary, in order to move the celestial bodies, to multiply innumerable Intelligences — as many, says Tannerus, as there are Fixed stars, and as many as there are spots on the Sun. [Margin: Response.] The answer is to deny the antecedent. For the heavens of the Planets can be posited liquid, and the heaven of the Fixed stars solid and movable by one Intelligence or a few; and the spots around the Sun, since they are bodies very close to it and erupting from it, are easily carried round by the Sun's own rotation; or else a single Intelligence could preside over several of them that are near one another, to move and direct them — if an Intelligence is said to be needed for this at all. As for the Planets, it is the asserters of solidity who multiply far more entities, those of the Eccentrics and Epicycles.

XI. [Margin: 9. Argument, of Tannerus.] The *ninth* argument. If the solidity of the orbs is admitted, the Divine craftsmanship shines out more in the machine of the heaven, out of many and various orbs, like a clock, skilfully com- posed, and in which the stars are set like gems in rings. Likewise, that subordination of influences and motions in the lower heavens with respect to the higher, which St Dionysius the Areopagite and our holy Patriarch Ignatius [Ignatius of Loyola], in the letter on Obedience, supposed, is better preserved. [Margin: Response.] The answer, however, is that this craftsmanship shines out no less if GOD from the beginning infused into the Angelic minds the species and idea of the motions, by virtue of which they can move the Planets certainly and infallibly and direct them to their ends — yet in such a way that the lower look to the higher and strive to imitate something in them. For this craftsmanship is rational and intellectual, and that is surely nobler than mechanical craftsmanship; just as a painter who could draw a perfectly straight line without any rule, or a perfectly round circle without compasses, would be far more excellent than one who could do neither without the aid of rule and compasses. Indeed, if the Orbs of the Planets consisted of solid Eccentrics and Epicycles, either the craftsmanship would be poorer, if the orbs were moved by themselves without an Intelligence, or the Intelligences would have no need of excellent knowledge, but only of motive force. But the good Father Tannerus, a German, too devoted to those clockwork machines perfected in Germany, seems to have been unable to imagine anything more excellent in this matter. I said "perfected", because it is known to us that Iannellus of Cremona [Gianello

Torriano], architect to Charles V — or, as they call it, *Organopoeius* (maker of instruments) — began to sketch out the machine of a striking clock in his house at Cremona, and that afterwards some German or other, having inspected it, perfected it and brought it to a better form; and this deserves not the least praise.

XII. [Margin: 10. Argument.] The tenth and last argument is indicated by Palingenius [Marcello Palingenio Stellato] in the *Aquarius*. Reduced to form, it is this: the longer something lasts in its state, the harder and more solid it is, and conversely; but the heaven lasts in its state from the beginning of the world to its end; therefore the heaven is supremely hard. [Margin: Response.] The major premise, however, is denied unless other things are equal. For earth is not more durable than water and the whole air, nor an apple than oil, nor the flesh of dead animals than water drawn off by distillation. The verses of Palingenius, moreover, are those written below:

> *But the heaven is eternal, and so is consumed by no age; But since things that are harder are more lasting, And are harmed less, the aether is therefore hardest, Harder than adamant, so that it scorns iron and fire And every force but the Lord's, by whom it was itself created.*

Expenduntur Argumenta pro Fluiditate Cælorum, & Reſponſiones ad illa adducuntur.

The Arguments for the Fluidity of the Heavens Are Weighed, and Responses to Them Are Adduced.

XIII. [Margin: 1. Argument: the authority of Holy Scripture.] The *first* argument is the authority of the divine writings. For it is said in Isaiah 51: *The heavens shall melt like smoke*; where the Septuagint reads: *The heaven has been made firm like smoke*. Following this version, St Basil says in homily 1 on the *Hexaemeron*: *But concerning the substance of the heaven, what was said by the Prophet Isaiah satisfies us; in common words he disclosed to us a fitting sense of its nature when he said, who made the heaven firm like smoke — that is, who produced a thin nature, neither solid nor thick, for the composition and substance of the heaven.* Furthermore, Holy Scripture never attributes motion to the heaven except by miracle, as when it is said in Isaiah 34: *The heavens shall be folded up like a book*; and in Joel chapter 2: *Before his face the earth trembled, the heavens were moved*; and chapter 3: *The heavens and the earth shall be moved*. But whenever the discourse is of the natural motion of the stars, of the Sun and the Moon for instance, that motion is never attributed to the heaven, as is clear to anyone who reads Holy Scripture, and from the places I have already reviewed in chapter 2, number 5.

[Margin: 1. Response.] It can be answered that that version of the Seventy does not outweigh the Vulgate, or the versions of St Jerome, Pagninus, Vatablus and Arias Montanus; that the likeness of smoke is not suited to explaining firmness; and that from the Hebrew word *Racha* it should rather have been rendered *they were expanded*, or *they shall be expanded*. Or else the sense is that the heavens, according to the form and conditions of the present time, have no greater duration than smoke has, but that they too are to be transformed very

swiftly; as it is said in Psalm 36: *Like smoke they shall vanish*; and in Psalm 101: *My days have vanished like smoke*. Further, Holy Scripture expresses only the motion of the Sun and the Moon, because that motion alone is manifest to the common people and strikes the eye, and because the Planets are the bodies for whose sake the heavens are moved, if they are moved: just as a horseman, or someone carried in a chariot, is said to arrive in a city, even though his horse or chariot has arrived too. It can happen, therefore, that the heavens too are moved, and yet Scripture says nothing of their motion, as being less perceptible and less principal. This response is that of Pererius on Genesis, book 2, question 9; of Martinengus in the *Glossa* on Genesis, page 1019; and of Amicus, above, article 5.

[Margin: 2. Response.] It could be answered, secondly, that even if the stars moved while the heaven was unmoved, it would not follow from this that the heaven is liquid. For someone could admit, with Arriaga, single disputation *On the Heavens*, number 26, a vacuum in the heaven through which not only the stars but also the Epicycles are carried — for he says that a vacuum is prevented by God only in sublunary things; or, if this is too bold, he could admit the penetration of the stars with the heaven, which others already named in number 6 have admitted.

XIV. [Margin: 2. Argument: the authority of the Fathers [?].] The *second* argument is the authority of 30 Fathers and Doctors cited by Father Schombergerius. Some of them denied that the Firmament is solid with a solidity that includes hardness; others affirmed that the Planets move of themselves in the heaven, the heaven itself being unmoved, and so move like birds in the air and fish in the water, and that the heaven is therefore liquid. Their words I have already reported in chapter 2, question 2. For to say, as Amicus says, that they deny to the heaven only such solidity as elementary bodies have, is forced and arbitrary; otherwise the same could be said of the solidity of the heaven that he strives to confirm from the Fathers. [Margin: 1. Response.] It could therefore be answered better that many other Fathers stand for solidity, and that therefore either one is free to follow whichever side one likes, or they are to be reconciled so that some asserted the solidity chiefly or solely of the supreme heaven, that is, the heaven of the Fixed stars, and others the fluidity of the Planetary heaven; how much foundation this distinction has in the Fathers I have already made plain in chapter 3, conclusion 4. [Margin: 2. Response.] The answer, 2, is that from the statements of those who say that the Planets move while the heaven is unmoved, the fluidity of the heaven does not follow, because one could admit either a vacuum in the heaven or the penetration of bodies, according to what was said in number 6 and at the end of number 13.

XV. [Margin: 3. Argument, from the superfluity of motions and instruments.] The *third* argument. So many real and solid orbs of the Planets, and their motions, are multiplied in vain — indeed not only in vain but with the danger of mutual collision and hindrance, given so great a variety of motions; or at any rate we are compelled, without necessity, to weary the imagination

in conceiving so many real and solid Epicycles, Eccentrics, Concentrics, EccentrEpicycles, *circitores*, *anticircitores*, *vecti*, *contravecti*, etc. Finally, it seems unbecoming to the divine Wisdom that, for the sake of the motion of one Planet — Saturn, say — which can very easily be moved by itself or by an Intelligence, so great and so vast a machine should be moved as the whole heaven of each Planet is. For the Planet, compared with its heaven, is no more than a point, and is smaller than a drop is with respect to the Ocean; just as it would seem unbecoming if, for the motion of one droplet of water, the whole Ocean, which would otherwise be immovable, were moved; or if, to move an ant, the whole earth had to be shifted. Thoroughly moved by this argument, which concerns a fittingness partly physical and partly moral, Arriaga, single disputation *On the Heavens*, number 53, conceded so far as to assert that it is more probable that the heavens of the Planets are liquid.

[Margin: Response.] Tannerus and Amicus nevertheless respond that in the structure of these Machines and the subordination of their motions the craftsmanship of the supreme Maker, and his Omnipotence, appear the more, as does the power divinely communicated to the Intelligences for moving such vast bodies perpetually.

XVI. [Margin: 4. Argument, from the trajection of the Comets.] The *fourth* argument is taken from the multiple and wandering motion, or free and oblique trajection, of those Comets which Tycho and others are held to have demonstrated to have been generated and moved above the Moon. For this was thought to have been demonstrated of many Comets by the Astronomers: both by those whom we adduced in book 8, section 1, chapter 23, and, on the occasion of this controversy about solidity, by Scheiner in the *Rosa Ursina*, pages 740 and 765; Oviedus, number 15; Tellez, disputation 40, number 7, and, cited by him, our Father Ignatius Stafford, a distinguished Mathematician, in manuscripts; and, cited by Oviedus, our Eusebius, book 6 of the *Philosophy*. Now if the heavens were solid, their whole mass would have gone into the Eccentrics, Concentrics and Epicycles of the Planets, and neither matter nor place would remain for the Epicycles of the Comets. Therefore, from the

trajections of the Comets, Kepler, in the *Epitome of Astronomy*, book 4, page 442, held that the fluidity of the heaven had been demonstrated by Tycho, saying: *Tycho Brahe refutes solid orbs by three arguments: one is from the motion of the Comets, the second from unrefracted Light, the third from the proportion of the orbs. For if the orbs were solid, Comets would not be seen passing from one orb into another, since they would be impeded by the solidity; but they do pass from one into another, as Tycho demonstrated.*

[Margin: 1. Response.] Tannerus, Amicus and Hurtadus nevertheless *respond* that it has not been demonstrated that any Comets were above the Moon. They dared to say this without any discussion of Tycho's arguments, which are drawn chiefly from parallax, and not without the risk of earning ridicule or indignation from those skilled in Astronomy and Geometry. For this reason I judged that I should undertake, to this end as well, all the labour which, God

favouring, you have already seen carried through in book 8, section 1. There, in chapter 23, I finally concluded that it has not indeed been demonstrated so far, absolutely, that any Comet was above the Moon, but that it has been demonstrated on a certain hypothesis that is highly probable.

[Margin: 2. Response.] Secondly, therefore, Tannerus, Oviedus, Arriaga and the others named in the same book 8, section 1, chapter 6, number 12, *respond* that Comets, as well as new stars, are portents created or made in the heaven divinely, and not without a miracle, to rouse, terrify and warn mortals, etc. They can therefore also pass from one orb into another in a supernatural way, whether by penetration or by reproduction, however solid the orb were granted to be.

[Margin: 3. Response.] Thirdly, Fracastorius [Girolamo Fracastoro] *would respond*, in the *Homocentrica*, section 3, chapter 23, that there is in the heaven of the Moon a certain orb that serves the motion of the Comets in latitude; though he says that these Comets are moved in the air, and he acknowledges the difficulty of his response. In the same way, then, someone could feign within the orbs of the Planets still other orbs, really distinct and assigned to the motion of the Comets. How difficult that would be, let him judge who knows what we related about the motions of Comets in book 8, section 1, chapter 3.

XVII. [Margin: 5. Argument, from the motion of the satellites of ♄ and ♃.] The *fifth* Argument arises from the motions of the satellites of Saturn and Jupiter, on which see what I set out in book 7, section 1, chapters 1 and 3, and section 6, the last chapter. For there is so great a variety in them that the solidity of the heaven seems inadmissible around Saturn and Jupiter, lest it impede such motions. To say with Tannerus and Arriaga that it is not yet certain whether these are Fixed stars, visible only through the telescope, rather than wandering ones, is surely to show oneself less skilled in astronomical matters. [Margin: Response.] The same authors therefore *respond* better that all their motions, since they are after all regular, can come about through particular Epicycles around Saturn and Jupiter, hollowed out within the greater Epicycle of Saturn and of Jupiter.

XVIII. [Margin: 6. Argument, from the motion of ♂.] The *sixth* Argument arises from the motion of Mars. For we have already described, with Kepler, in book 7, section 1, chapter 8, its Spirals and windings as well, wonderfully tangled and intricate. Next, we showed that Mars is indeed carried above the Sun when it is near its Apogee and its conjunction with the Sun, but descends below the Sun and penetrates the Solar heaven when, having become acronychal, it tends towards its Perigee and its opposition with the Sun. We showed this both from the increase of its apparent size at perigee and from the parallax, which must be greater in it than in the Sun if the place of Mars in longitude and latitude, deduced from the tables or from the geometrical construction of the hypothesis, is to agree with its place as then observed with precise instruments. This, I say, we showed — or taught that it had been shown by Copernicus, Tycho and Kepler — already in book 7, section 2, chapter 3,

Scholium 4, and section 6, chapter 4, Scholia 3 and 4, and chapter 10, Scholium 1. There we also reproved Tannerus, Carolus Malapercius [Charles Malapert] and Bartholomaeus Amicus [Bartolomeo Amico], because, out of excessive love for the solidity of the Planetary heaven, they dared to deny that descent of Mars below the Sun without any examination of the Tychonic or Keplerian observations or demonstrations. Yet this descent can be gathered by those skilled in Astronomy and Geometry even from the mere comparison of the apparent diameter of Mars near apogee with its apparent diameter near perigee, as may be seen from what we said in book 7, section 6, chapter 10, Scholium 1. Certainly Lansbergius [Lansbergen], Maginus [Giovanni Antonio Magini], Galileo, Boulliau, Gassendi and all the most expert in astronomical subtleties have yielded to Tycho and Kepler on this point — except Rothmann, who, although he holds the heavens to be fluid, thought that the order of the heavens would be disturbed if he conceded that Mars is carried now above, now below the Sun; though this must be conceded of Venus and Mercury, as we shall shortly say. Just as Tannerus defends the ascent and descent of Mercury and Venus by Epicycles around the Sun, therefore, so he could have defended that of Mars too, as *Oviedus* rightly argues against him, single controversy *On the Heavens*, point 3, number 22.

[Margin: Response.] *Tannerus* therefore *responds*, in his dissertation *On the Heavens*, question 7, page 158, and in volume 1 of the *Summa theologica*, disputation 6, question 3, doubt 3, number 78 — and *Amicus* with him, treatise 5 *On the Heavens*, question 5, article 5, number 30 — granting such a descent without conceding it: *Perhaps it is not impossible, even if the solidity of the heavens stands, to save such Phenomena, if the heavens of Mars and of the Sun, interlocked with each other, are revolved together; and if it is needed for saving the Eccentricity of Mars, let its own Epicycle be added to it besides; or else let the Eccentrics of the Sun and of Mars be so disposed that Mars at perigee [hypogaeo] is nearer the earth than the Sun at apogee. Some more recent Mathematicians add that this could also come about if Mars and the Sun were moved in certain zones, as it were, or rings, interlocked with each other in a certain way, so that each in turn could rise above the other and again pass beneath it. This I leave to the Mathematicians to explain in their own time.* But it was wrong to set these doubtful modes, not yet demonstrated by any diagram, against the observations and demonstrations of the Astronomers. Nor ought one, with obscure hypotheses feigned in confusion of mind, to build up with a vain or superfluous effort a heaven of the Sun intersected by the heaven, the Epicycle or the Eccentric of Mars, when, once the liquidity of the heaven is admitted, the motion of each Planet can be explained far more easily and more fluently, without the danger of an inconsistent and self-contradictory system. The more recent Astronomers, therefore, and posterity, will rightly judge — for as long as the contrary has not been demonstrated — that the solidity of the Solar heaven is shattered by this argument, as by a most powerful weapon of Mars and, as it were, a thunderbolt, especially in view of the most tortuous spirals of that planet.

XIX. [Margin: 7. Argument, from the motion of ☿ and ♀.] The *seventh* Argument rises from the motion of Venus and Mercury. We showed in book 7, section 1, chapters 2 and 4, that it has now been made plain by the Telescope and by the most evident phenomena that each of them circles the Sun, and is carried sometimes above it, sometimes sinks below it. Since, moreover, they do not digress from the Sun beyond 50°, their Epicycle must intersect the orb of the Sun. Although this seems able to happen with the solidity of this heaven kept intact, yet there is so great a difficulty in it — especially in view of the spirals and windings of Mercury, which surpass every most tortuous coiling of the serpents he holds twined round his caduceus — that it is better to allow a free and permeable heaven for explaining them than to be entangled in them so as to defend, tooth and nail, a solidity that is otherwise of no use or convenience.

XX. [Margin: 8. Argument, from the spots of the Sun.] The *eighth* Argument is drawn from the spots and faculae that bubble up around the Sun and, with varied motion, seem to riot as it were — in alternating surge, or in rotation, and in running together into one, or in scattering and dispersal into various smaller spots. Although this motion could be accomplished by innumerable Epicycles, it is better that it should come about freely in a fluid heaven.

XXI. [Margin: 9. Argument, from the roughnesses of the ☾.] The *ninth* Argument is drawn from the roughnesses of the Moon, namely the valleys, mountains and caverns on its surface, made manifest by the Telescope just as on the earth, as is now established from what was said in book 4, chapter 7. Lest a vacuum be admitted within them, therefore, it seems that a liquid and yielding aetherial air must be admitted around the Moon. The assertors of solidity, however, *will respond* that the globe of the Moon is so set into an Epicycle that the hollows of those roughnesses are filled by solid parts of the Epicycle, just as the kernel of a nut, or the seeds of a pomegranate, are set into their rind.

XXII. [Margin: 10. Argument, from the Refraction and Reflection of rays.] The *tenth* Argument Tycho took — as I reported from Kepler in number 16 — and so did *Bullialdus*, in book 1 of the *Astronomia Philolaica*, chapter 4, from the multiple Refraction of the rays of the Sun and of the other stars that would take place at the surfaces, convex as well as concave, of so many Epicycles and Eccentrics. By reason of it rainbows or wonderful colours would be seen in the heaven, and the figures of the stars and their mutual distances would be varied everywhere. Indeed Boulliau thinks that, from the reflection of the Sun's rays, there would never be night, but that in the opposite part of the heaven an image of the Sun, as in a mirror, would by night

be seen. All these things conflict with the daily Phenomena of the stars.

[Margin: Response.] *Amicus responds* that all the heavens are of the same density and rarity, and behave like several lenses, or several spectacle-glasses, concave on one side and convex on the other, laid one upon another; for if they are of the same material they do not vary a refraction once made. From this, however, it would follow that the apparent sizes of the stars are made uncertain

— unless someone feigns that the refraction made in the heavens towards the perpendicular is compensated by the refraction made in the air away from the perpendicular, and that the images of the stars are thus restored to the original size that would appear to us if no refraction intervened. *It could*, however, *be answered* that solidity and hardness are not an accident that necessarily has density joined to it in the heavens. For even among sublunary things some are harder than others and yet rarer, as ice is with respect to water not yet frozen: ice rarefies and swells, and holds lighter exhalations within itself, by virtue of which its body is made lighter than water of equal bulk, and for that reason ice floats on water. Conversely, lead is denser than silver, and yet less hard. It can happen, then, that the aether has a rarity as great as that of the most purified air, and yet a hardness and solidity greater than a crystal's. And certainly those who posit the sphere of the Fixed stars as solid must, for their part, clear it of the variety of refractions and reflections already mentioned.

VNICA CONCLVSIO.

Single Conclusion.

XXIII. *It is much more probable, though not yet evident Mathematically or Physically, that the heaven of the Fixed stars is solid, but that of the Planets Fluid.*

This is established from the arguments and responses on both sides adduced so far. For by this distinction — both of probability from evidence, and of the heaven of the Fixed stars from the heaven of the Planets — very many opinions of the Fathers and Doctors are reconciled with one another and with the observations of the more recent Astronomers. With less violence, and less multiplication of motions and machines, and also with less danger of physical conflict among the so varied motions of the Planets, the Phenomena of the Comets, of Mars, of Venus and of Mercury are explained, which are the chief ones in this business — and indeed the motions of the Companions of Saturn and Jupiter, and of the Solar Spots as well. Conversely, if the sphere of the Fixed stars is posited as solid, a readier account is given of why they perpetually keep the same distance from one another, and innumerable movers of the Fixed stars will not have to be multiplied. Indeed, since almost that whole heaven is crammed with stars, as the Telescopes show, there is nothing unfitting in God's having ordained the motion of so vast an orb in order to move so many stars, which taken together occupy a great part of it. But to posit the heaven of the Moon as solid is to make it impervious to Comets, if any happen to be formed in it or to ascend upward through it. Nor is it probable that the volatile salts or spirituous parts of the earth reach up as far as the heaven of the Moon, or, if they did arrive there, that they could rebound downward with such force as to descend 50 and more semidiameters of the earth and return to ferment the earth; for, being light, they would rather wander round about the concave of the Moon, like smoke about the vault of a room. The heaven of the Moon is therefore not to be posited as solid for that reason, as our Cabeo wanted.

CAPVT VIII.

Chapter VIII.

VTRÙM CÆLI & AſTRA ſINT ANIMATA.

Whether the Heavens and the Stars Are Animate.

I. [Margin: 1. Opinion, making the stars Gods.] The First Opinion, and the most ancient, held by very many, was that the heavens and the stars are animated by an intellective soul that is blessed, and indeed even divine. [Margin: Egyptians, Stoics, Athenians.] For the Egyptians and the Stoics numbered the stars among the Gods, as Theodoret reports in book 3 *On Evil Gods* [de Dijs malis], and Eusebius of Caesarea in book 1 of the *Praeparatio Evangelica*, chapter 6. Indeed the Athenians did so too: for St Augustine, in book 18 of the *City of God*, chapter 41, and Laertius [Diogenes Laertius], in the life of Anaxagoras, report that this very Philosopher, namely Anaxagoras, was condemned for impiety by the Athenians because, in asserting that the Sun is a fiery stone, he made it out to be neither a God nor animate. [Margin: Lucillus.] *Lucillus* the Stoic certainly argued as follows, in Cicero and in Lactantius, book 2, chapter 5: *This constancy, then, in the stars, this so great agreement of times in such varied courses through all eternity, I cannot understand without mind, reason and counsel; and since we see these in the stars, we cannot but place the stars themselves in the number of the Gods*; and a little before: *It remains*, he says, *that the motion of the stars is voluntary; and whoever sees this would act not only ignorantly but also impiously if he denied that the Gods exist.* [Margin: Cleanthes [?].] *Cleanthes* believed the same, in Cicero, book 2 *On the Nature of the Gods*; [Margin: Plato.] and so did *Plato*, in the *Epinomis* and in the *Timaeus*, whose words addressing the stars as Gods St Augustine reports in book 13 of the *City of God*, chapter 16; and St Cyril testifies the same of Plato in book 2 *Against Julian*. But Plato and the Stoics also added a vegetative soul, as I shall say in number 4.

II. [Margin: 2. Opinion, that of Philo.] The *Second* Opinion was that of those who thought the stars animated by an intellective soul, yet without placing them among the Gods. For *Philo* says in the book *On Dreams*: *that the individual stars are called not only living beings but also most pure minds.* And in the book *On the Giants* he says: *It is necessary that the whole World have a soul in all its parts, etc. The heaven likewise, and the stars. For these are wholly immortal and divine souls, and for that reason they are moved in a circle, a motion akin to mind. For the mind of each one of them is most perfect.* [Margin: Of Rabbi Moyses.] This very view is ascribed to *Rabbi Moyses* [Maimonides] by Martinengus, page 881, and by the Coimbra commentators [Conimbricenses], book 2 *On the Heavens*, chapter 1, question 1. [Margin: Of Origen.] *Origen*, however, in homily 28 on Numbers, and more clearly in book 1 of the *Peri Archōn* [Greek: περὶ ἀρχῶν (peri archōn, "On First Principles")], chapter 7, and in volume 1 of the *Commentary on John*, considering the words of Isaiah chapter 45, *I have commanded the host of heaven*, concludes after much discussion: *But since the stars*

are moved with such order and such reason that their course has never at any time been seen impeded in anything at all, how is it not beyond all stupidity to say that so great an order, and so great an observance of discipline and reason, is demanded of or fulfilled by irrational things? Next, because of the saying in Job 25, *The stars are not clean in his sight*, he judged that the stars are capable of vice and virtue. Finally, because in Romans 8 the creature is said to be subject to vanity and to be freed from bondage, he held that the souls of the stars are to be freed from the body of their globe, and that the souls of the stars were once outside their globes but were afterwards drawn down into them, as into a prison. There are also those who suspect that *Athanasius* partly adhered to Origen, because, expounding the words of Matthew 11, *All things have been delivered to me by my Father*, he adds: *The Angels did not keep their order, and the stars are not held pure before him, and the devil fell from heaven, and Adam transgressed.* [Margin: Of Caietanus.] Among the more recent writers, too, *Caietanus*, on Psalm 133 and in the treatise on indulgences, expounding the words *Who made the heavens in understanding*, and those in the Preface of the Canon of the Mass, *The heavens and the powers of the heavens*, says: *What does he understand by the powers of the heavens? The Angels, the movers? But he listed the Angels themselves above, and ought not to have repeated them. The forces of the heavens themselves? But he ought not to have mixed insensate things with the Angelic orders, and the speech would then have been inept if the forces and accidents of the heavens were coupled with the most excellent substances. Therefore by the powers of the heavens he understood the very souls of the heavens and of the stars.* [Margin: The hesitation of Cassiodorus and of Haymo.] *Cassiodorus*, likewise, shows himself doubtful on this question, on Psalm 148, when he says: *Therefore the Prophet commanded the Sun, the Moon and the Stars to praise the Lord, whether through their own reason or through other substances, sensible and able to be declared.* So too *Haymo*, on the same psalm, showed his hesitation, saying: *If the Sun is said to have a spirit, and the Moon and the other Stars can praise God of themselves: if they do not praise you well because they are matter, why should we praise you?* [Margin: What of St Jerome?] To some, *St Jerome* also seemed doubtful on this, because in book 9 on Isaiah, explaining the words *The light of the Moon shall be as the light of the Sun, and the light of the Star shall be sevenfold*, he says: *That the Moon and the Sun may obtain the rewards of their labour and of their course.* And on chapter 1 of Ecclesiastes, expounding of the Sun the words *The spirit goes on*, among other expositions he gives one according to the mind of Virgil and of Plato, saying: *Or because a spirit within nourishes both the shining globe of the Moon and the Titanian stars, and mind, poured through the limbs, moves the whole mass, etc.* But he himself expressly condemns Origen's opinion, both in letter 59, to Avitus, and in book 13 on Isaiah. [Margin: What of St Augustine?] Likewise *St Augustine*, in book 2 of *De Genesi ad litteram*, chapter 18, seemed to doubt, as also in book 13 of the *City of God*, chapter 16; but

afterwards he retracted it, in book 1 of the *Retractations*, chapters 5 and 11. [Margin: What of St Thomas?] The other light of the Theologians, *St Thomas*,

following Aristotle, teaches in the *Disputed Questions*, the question *On the Soul*, article 8, in the second book *Against the Gentiles*, and in the *Opusculum on the Angels*, that the celestial bodies are informed by a certain intellective soul, which strives in the motion of the heaven to imitate the divine likeness; which, according to the Philosopher, from book 2 *On the Soul* and book 11 of the *Metaphysics*, is purely intellective, and not also imaginative, as Avicenna would have it; and which, finally, could have sinned but did not sin, and belongs to the company of the Angels. Nevertheless, in the first part, question 70, article 3, he concludes that the soul of a celestial body is not united to it as a form, because it is helped by the body in no operation, but only as a mover to a movable thing, by contact of power. His last words are: *It remains, therefore, that it is united to the celestial body for the sake of motion alone* — understand this — *but for it to move, it is not necessary that it be united to it as a form, but by contact of power, as a mover is united to a movable thing*; and he adds the example of the first mover that moves itself, composed, according to Aristotle in book 8 of the *Physics*, of a moving part and a moved part, which are united by contact; and finally, *The Platonists too*, he says in the same place, *held that souls are united to bodies only by contact of power, as a mover to a movable thing.* From this passage Caietanus and many Thomists judged that St Thomas changed his opinion, as one who had left his last will declared in the *Summa*, as in a testament; but Ferrariensis [Francesco Silvestri], book 2 *Against the Gentiles*, chapter 70, and Vielmius think that he adhered constantly to neither side. [Margin: Vielmius's opinion.] Vielmius himself, the teacher of Ascanius Martinengus, judged in lecture 19 on Genesis that this is a problem, notwithstanding the decree of the University of Paris. For he says, in the question whether the heaven is animate: *And let this much be said for the negative opinion, which I do not in the least doubt is the more probable — so much so that the affirmative was long ago placed among the articles condemned at Paris, as Richardus writes in the place cited. But nonetheless I think that the arguments brought on both sides can be answered in the diatribes in such a way that it appears with certainty both that those who thought otherwise were not unlearned, and that it is not wicked even now to discuss it.* [Margin: Aureolus, Scotus.] *Aureolus* [Pierre Auriol], on book 2, distinction 14, question 2, article 2, and question 3, article 1, and *Scotus* in the same place, question 2, likewise judged the affirmative side, concerning an intellective soul of the heaven, to be probable in view of the arguments, Scotus saying: *If the stars are not animate, that will have been believed rather than demonstrated.*

III. [Margin: What of Aristotle?] So much for the ancient Philosophers before Aristotle, and for the Theologians. What Aristotle thought, however, and after him the Peripatetics and the other Philosophers, is disputed. For in book 2 *On the Heavens*, texts 13 and 61, and in book 2 of the *Metaphysics*, text 35, he seems to attribute to the heaven an intellective soul as its form; and so he is interpreted by Themistius, Averroes, Simplicius and Philoponus, and also by *St Thomas*, book 2 *Against the Gentiles*, chapter 50, and in the *Disputed Questions*, the question *On the Soul*, article 8, reply to 3; by *Vasquez* [Gabriel Vázquez]

on the first part, question 183; *Niphus* [Agostino Nifo], book 1 *On the Substance of the Orb*, chapter 29; *Pomponatius* [Pietro Pomponazzi], *On the Immortality of the Soul*; *Achillinus* [Alessandro Achillini], book 3 *On the Orbs*, doubt 1; and *Balduinus* and *Mercenarius* in the question *On the Soul of the Heaven*. But from book 8 of the *Physics*, texts 40, 41 and 52, and book 12 of the *Metaphysics*, texts 30 and 43, it seems to be gathered that Aristotle does not attribute an Intelligence to the heaven as an informing form, but only as a pure act that assists it, like a sailor his ship — and indeed not even as moved along with the motion of the heaven. So he is interpreted by *Scotus*, quodlibet 7; *Piccolomineus* [Francesco Piccolomini], *On the Heavens*, chapter 17; *Iandunus* [Jean de Jandun], book 2 *On the Heavens*, question 4; and *Alexander*, as cited by Simplicius. An intellective soul was likewise attributed to the heaven by *Iamblichus*, *Porphyry* and *Proclus*, as cited by Psellus on the oration of St Nazianzen, 38 and 42; by *Julius Firmicus*, book 1 of the *Mathesis*, chapter 3; by *Bellantius*, as cited by Alexander de Angelis, book 1 *Against the Astrologers*, chapter 13; by *Marsilius Ficinus*, in the dialogue *On the Laws*, argument 10; and by *Carpentarius*, himself a Platonist, chapter 12.

IV. [Margin: 3. Opinion, on a vegetative and sensitive soul of the heavens.] The *Third* Opinion was that of those who attributed to the heaven, besides an intellective soul, a sensitive one as well, and indeed a vegetative and a locomotive one too. Among them are those who thought that the stars are nourished, of whom *Plutarch* speaks thus in book 2 *On the Opinions*, chapter 17: [Margin: Heraclitus, Plato, the Stoics.] *Heraclitus and the Stoics hold that the stars are nourished by vapours rising from the earth. Aristotle, that the celestial bodies do not need nourishment, for they cannot be corrupted, but are eternal. Plato and the Stoics, that the stars, like the whole universe, take nourishment*; but Plato should be read in the *Epinomis*. [Margin: Pliny.] Of this opinion, without doubt, was *Pliny the Elder*, book 2, chapter 8: *Not so great*, he says, *is the fellowship of the heaven with us that the brightness of the stars too should be mortal by our fate. Through excessive nourishment of the moisture drawn up, they give back its fiery force in abundance when they are believed to fall*; and in chapter 9 he refers the spots of the Moon to this, saying: *But the stars are without doubt fed on earthly moisture, since at half orb the Moon is never seen without spots — its force, that is, not yet being sufficient to draw up beyond its due. For the spots are nothing other than the dirt of the earth carried up with the moisture.* [Margin: Avicenna, Simplicius.] *Avicenna*, moreover, book 9 of the *Metaphysics*, chapter 2, besides an intellective soul moving the heaven remotely, gave it a sensitive soul produced by the intelligence, so that it might move it proximately by the imagination of a sensible motion[25]. *Simplicius*, on book 1 *On the Heavens*, text 50, added three external senses, namely sight, hearing and touch. [Margin: Tycho.] *Tycho*, for his part, in the *Epistolae* of the year 1590 to Rothmann, recognized a divine, and moreover a vital, spirit in them, saying: *But these things happen in the celestial bodies in a certain celestial manner, livelier and more refined than in terrestrial or marine animals; since that divine*

[25]the print reads "mo ûs", the t not printed

philosophy of the Platonists seems, not without reason, to have held that the heaven too is animate, and that the celestial bodies themselves are certain living creatures of the heaven, endowed with a vital spirit. [Margin: Kepler.] Lastly *Kepler*, in the book *On the New Star* and in the *Physiologia* of comets, attributes to the heaven a certain soul whose office it is to gather, at certain times, the soot and filth of the heaven, which would taint the splendour of the Sun and the stars and the pellucidity of the aether if they were not kindled into Comets. For when a great quantity of such filth has arisen, *then*, he says on page 99, *there is need of defecation and purging, which that faculty performs which is in the very substance of the aetherial air, a faculty similar to an animal or vital one.* And in the introduction to the commentaries on Mars he will have it that the Sun is endowed with a soul, which preserves for the Sun its light and its power of moving the other Planets; he calls it a motive soul, one that gives the Sun a corporeal life. [Margin: Baranzanus.] And *Baranzanus* [Redento Baranzano], in part 1 of the *Uranoscopia*, question 2, doubt 3, attributes to the celestial bodies a certain soul intermediate between the intellective and the brute soul, agreeing with these only analogically.

V. [Margin: 4. Opinion, the Negative.] The *Fourth* opinion, the true and sound one, is that the Heaven and the stars are inanimate, and wholly lack any soul that would be a form informing the celestial bodies; but that if they are moved by an Intelligence, they are moved by it not as by an informing form but as by an assisting Mover. For this opinion there contend, first of all, *Catherinus*, on chapter 1 of Genesis, where he denies that Caietanus's opinion can be defended by a Christian; *Ascanius Martinengus*, in the *Glossa magna*, pages 887 and 890, who, though he thinks it a problem — setting aside Origen's error — whether the stars are animated by a rational soul, nevertheless confirms by arguments and authorities that the negative side is far more probable; *Mastrius and Bellutus*, disputation 2 *On the Heavens*, question 2, article 2, from number 62; and *Io. Poncius*, disputation 22 of the *Physics*, question 3. Among the writers of our own Society there are *Pererius*, on Genesis, book 2, question 7; the *Coimbra commentators*, book 2 *On the Heavens*, chapter 1, question 1, article 2; *Toletus* [Francisco de Toledo], book 2 *On the Heavens*, chapter 5; *Rubius* [Antonio Rubio], book 1 *On the Heavens*, chapter 2, question 8; *Tannerus*, dissertation *On the Heavens*, question 4, and volume 1 of the *Summa theologica*, disputation 6, question 2, doubt 5; *Amicus*, treatise 3 *On the Heavens*, question 4; *Arriaga*, single disputation *On the Heavens*, section 2; *Oviedus*, single controversy *On the Heavens*, point 1; and *Balthassar Tellez*, disputation 43 of the *Physics*, in whom many scholastics are cited. Let this, therefore, be the

VNICA CONCLVSIO.

Single Conclusion.

The Celestial Bodies are animated neither by an Intellective or rational soul, nor by a sensitive soul, nor by a vegetative soul.

VI. [Margin: 1. Argument.] It is proved, 1, by the Authority of the Fathers: especially of *St Cyril*, book 2 *Against Julian*; of *St Basil*, homily 3 on the *Hexaemeron*; and of *St Ambrose*, book 2 of the *Hexaemeron*, chapter 4 — the two of whom refute Origen even on this ground, that dew and frost, cold and hoar-frost would then also have to be called animate, because they are invited to praise God; of *St Gregory Nazianzen*, orations 38 and 42, where, as Psellus interprets him, he condemns the impostures of the Platonists about the soul of the heavens; and of *St Chrysostom*, in the homily on Psalm 4, where among other things he pronounces: *For the Sun has neither reason, nor mind, nor thought.* Likewise by that of Theophilus of Alexandria, in Paschal letter 1, where he says that Origen *builds up dogmas contrary to the faith*; and of *St John Damascene*, who says: *Let no one think the heavens or the Luminaries animate, for they lack soul and sense. Procopius* teaches the same, with St Basil, in the *Commentary on Genesis*; and *Lactantius*, book 2 of the *Divine Institutes*, chapters 5 and 8, sharply attacks the Gentiles with the argument that if, on account of their constancy in motion, the stars seem fit to be ranked among the gods, one ought rather to conclude from this that they lack not only divinity but also intellect and will. For if they were gods, endowed with intellect and will, they would wander freely here and there as they pleased; and since that does not happen, but they are compelled to weave the same path perpetually, like beasts fastened to a mill, their motion is not voluntary but necessary. Yet this argument would also strike at the moving Intelligences. For the remaining Fathers, see Ascanius Martinengus.

[Margin: 2nd argument.] It is proved, second, from the definition of the Church. In the Fifth General Council, which was the Second of Constantinople, among the other errors of Origen — as Nicephorus reports, book 17 of the *Ecclesiastical History*, chapters 27 and 28; Ioverius in the *Summa Conciliorum*, volume 2; and Liberatus in the *Breviarium*, chapter 23 — this one too was condemned by the decree: *If anyone says that the heaven, and the Sun, and the Moon, and the stars, and the waters that are above the heavens, are certain animate beings and material powers, let him be anathema.* Here "the material powers of the heavens" is taken in Origen's sense, as souls informing the bodies of the stars. Origen's error about the souls produced before the heaven, by contrast, the Council condemned separately, as Nicephorus reports in that same chapter 27; hence by this other decree a distinct error is condemned, namely the one by which an intellective soul is attributed to the heaven and the stars. Moreover, in the chapter *Firmiter*, on the Supreme Trinity and the Catholic Faith, no rational creatures are listed except Angels and Men; St Jerome counts this opinion among the heresies; and St Epiphanius, book 11 of the *Panarion*, and St Irenaeus, book 1 *Against Heresies*, list the opinion on the soul of the heavens among the condemned doctrines of the Marcosians.

[Margin: Censure of the opposite opinion.] On account of these and similar authorities, therefore, the opinion asserting that the heaven and the stars are animated by an intellective or rational soul is judged erroneous in faith by St Bonaventure, on [the *Sentences*] 2, distinction 14; by Petrus Tarantasius [Pierre

de Tarentaise], cited by the Carthusian on 2, d. 14, q. 2; by the *Directorium Inquisitorum*, from page 239 on; and by Tannerus, Tellez, Poncius and the Conimbricenses in the places listed above. That it is not consonant with the faith is taught by Capreolus [Jean Capréolus] on 2, d. 9, q. 1, art. 1, by Gabriel [Gabriel Biel] at the same place, q. 1, and by Pererius, book 2 on Genesis, q. 7; and Catherinus, on chapter 1 of Genesis, says that it cannot be defended by a Christian. Pineda [Juan de Pineda], on chapter 1 of Ecclesiastes, page 124, calls our opinion *a Doctrine of the Church and next to Faith*; Lorinus [Jean Lorin], however, at the same place, verse 6, denies that the opposite is an open error, granted that he holds, against Paulus Ricius [Paolo Ricci], that the heavens are not animate. But if anyone attributes to the heaven or the stars only a sensitive soul, or a vegetative one, or a locomotive one, that proposition is judged *absurd indeed and erroneous in Philosophy* by Tannerus, above, assertion 1, and by Tellez; and fit to be utterly hissed off and rejected by Martinengus — though not contrary to Faith. Granted, not even the opinion that gives them an intellective soul was thought erroneous in Faith by Vielmius, lecture 19 on Genesis, or by Martinengus in the *Glossa*, page 890, but rather to be a problem on the path of the Fathers [in via Patrum]. Yet this same Vielmius admits, on the authority of Ricardus, that it was condemned by the Academy of Paris.

[Margin: 3rd argument.] It is proved, third, by theological arguments. If those intellective souls were blessed and holy, it would be lawful to adore them with some cult and veneration — if not of latria, then at least of hyperdulia or dulia, as the theologians say. But this is against Deuteronomy, chapters 4 and 17, where the cult and adoration not only of foreign gods but also of the Sun, the Moon and all the host of heaven is forbidden; nor has the Church ever permitted this cult, even of dulia, towards the stars. On the contrary, it is execrable, as the sacred interpreters teach on that passage of Job: *If I saw the Sun when it shone, and the Moon advancing brightly, and kissed my hand in my bosom; which is the greatest iniquity, and an abomination before the most high God* — that is, if I adored the Sun and the Moon. And if those souls are damned, then the place of the damned would be in heaven itself, or the heavens and the stars would at some time have to be thrust down into hell and the eternal fire, which is the common place of all the damned, as is gathered from Matthew 25, verse 41. Since, however, someone could pretend that those souls are not capable of merit and demerit, I therefore add a fourth proof.

[Margin: 4th argument.] It is proved, fourth, because neither in the heaven nor in the stars do we have any indication a posteriori, from their operation, of a sensitive, vegetative or rational soul; nor do any organs appear in them that would be necessary, mediately or immediately, for these operations. Therefore an informing soul is posited in them rashly and without foundation. And if you say that those bodies do not need organs or dissimilar parts, this very kind of soul, animating a non-organic body, is nonetheless invented gratuitously; and for their regular motions the external direction of an assisting and moving Intelligence is sufficient.

[Margin: Objections resolved.] Nor does that verse of Psalm 135 stand in the way: *Who made the heavens in understanding*. It is to be understood of the wisdom of God himself, by which he founded and ordered the heavens and their motions, as St Augustine, Euthymius, Cassiodorus and Haymo expound it there; or of the Word, which is the Son of God, as St Bruno takes it. As for Psalm 18, *The heavens declare the glory of God* etc., Psalm 148, *Praise him, Sun and Moon*, and Job 38, *When the morning stars praised me*: these are understood objectively, not formally — that is, because the stars are an object highly suited to rouse Angels and men to praise God. Likewise Isaiah 45, *My hand stretched out the heavens, and I commanded all their host*, and Habakkuk 3, *They were called, and they said, Here we are* etc., are to be taken metaphorically; or else they indicate the obediential potency by which every creature, even an inanimate one, is subject to the command of God and serves it. Finally, the verse of Ecclesiastes 1 about the Sun, *Surveying all things round about, the spirit goes on its way*, can be understood either of the Intelligence governing the Sun or in other ways, of which below, in Section 2, where we treat of the movers of the heavens. [Margin: A soul lower than the rational may, without prejudice to the faith, be attributed to the stars.] It should be noted, however, with St Thomas, *Contra Gentiles* [book] 2, chapter 7, that it matters little to the Faith whether the stars are called animate or not, provided they are not said to have an intellective soul.

CAPVT IX.

Chapter 9.

An Cælum ſit Infinitum, & an Figuræ Sphæricæ.

Whether the Heaven is Infinite, and whether it is of Spherical Shape.

On the former question, so far as it concerns the astronomer, I shall set out the choicer points in Section 4, chapter 5, number 19. On the latter, that is, on the shape, see the same chapter 5, number 2, and Pliny's arguments, book 2, chapter 2, whose words we shall quote in that chapter 5, number 20. Meanwhile let us move on to other matters.

SECTIO SECVNDA DE MOTORIBVS ET MOTIBVS CÆLORVM.

Section Two: On the Movers and Motions of the Heavens.

CAPVT I.

Chapter 1.

CAPVT I.

An Cæli aut Sidera Moueantur ab Intelligentijs, An verò ab intrinſecò à propria Forma vel Natura.

Whether the Heavens or the Stars are Moved by Intelligences, or rather from within, by their own Form or Nature.

I. [Margin: 1st opinion: that their own form moves the heavens.] The first opinion was that the heavens are moved by their own form, that is, from within. Otherwise that form would be idle and inferior to the forms of the elements, since each thing exists for the sake of its own operation, as the Philosopher says, *De caelo* book 2, chapter 3, text 17; and otherwise that perpetual circular motion would be violent, since, from *Ethics* 3, chapter 1, that is violent whose principle is outside. And certainly there seems to be nothing to prevent God from making some body that has a natural appetite for perpetual circular motion, and so a power of moving itself perpetually in a circle — just as an impetus once impressed on a stone for motion in a circle would perhaps last perpetually, as some say, if it were not gradually destroyed by a contrary impetus produced by gravity. Since, therefore, there is no gravity or levity in heaven, what wonder if that impetus, once driving the celestial body in a circle from its origin by the force of its own form, revolves it perpetually? [Margin: Major, Parisiensis, Albert of Saxony, Gabriel, Trallianus, Strato.] Of this opinion, then, were Io. Maior [John Mair], *De caelo* book 1; Parisiensis [Guillaume d'Auvergne], *De Universo* part 2, chapter 152, who thinks the opposite vain and frivolous; Albertus de Saxonia [Albert of Saxony], *Physics* 8, last question; and others cited by St Bonaventure and by Bassolius on 2, d. 14, art. 3, q. 2; and Gabriel thinks it probable, at that place, q. 1, art. 3, doubt 2. In former times too, as the Conimbricenses report, *De caelo* 2, chapter 5, q. 1, [Margin: Pererius.] and Pererius on Genesis, book 2, q. 5, Trallianus and Strato of Lampsacus said that the motion from right to left, that is, from east to west, comes from an Intelligence, but that the motion from left to right comes from its own form.

[Margin: Longomontanus.] Among the more recent writers, Longomontanus, in the preface to book 1 of the *Theorics*, says that they are moved from within; [Margin: Vallesius.] Vallesius, by contrast, *Controversies* 11 and 26 on the *Physics*, teaches that they are moved partly by their own form and partly from without, since an Intelligence regulates the speed; [Margin: Camerarius.] and so Camerarius, disputation 25, who was moved by that verse of Psalm 18, *He exulted as a giant to run his course*, to think that the Sun is moved from within — although it is said metaphorically — and by that phrase in the Preface of the Mass, *the heavens and the Powers of the heavens*, where the powers of the heavens are counted as distinct from the Angels; as if the word "powers" could not there mean forces of influence, or indeed some order of Angels, since the Preface goes on to say, *and the blessed Seraphim*.

[Margin: Eusebius Nierembergensis.] Eusebius Nierembergensis [Juan Eusebio Nieremberg] inclines strongly to the same opinion in his *Philosophy*, book 6, on the life of the stars. He concedes, however, that for stirring up extraordinary motions, or for halting their motions, some Intelligence is appointed,

at one time or another: as when, at the death of Christ, the full Moon was brought back to conjunction with the Sun; and when the Sun's course was held back, not only at Joshua's command but also at the prayer of St Francis Xavier, [Margin: St Francis Xavier halts the Sun.] so that a ship being tossed by a violent storm might reach port before sunset — as Velasquez, Sherlogus and Oviedus (the single controversy on the heaven, point 1, number 7) relate of St Xavier. [Margin: Tellez.] Baltazar Tellez, disputation 44, section 3, affirms without qualification that the stars are moved by their own form. In disputation 40, section 3, he had also taught that if the stars are considered in themselves, without regard to lower things, circular motion is not connatural to them but comes from without; but if they are considered as what they are, the principal part of the universe, possessing natural powers of influence, it is natural to them.

The author of the *Philolaus* (book 4, chapter 2), [Margin: Bullialdus.] Ismaël Bullialdus [Ismaël Boulliau], likewise concludes, in book 1 of the *Astronomia Philolaica*, chapter 12, and in the *Philolaus*, book 4, chapter 2, that both the Sun, about its own axis at the centre of the world, and the other planets (among which he counts the Earth) are moved by their own form.

[Margin: Kepler.] Kepler, on the other hand, in the introduction to the *Mars* and in chapter 33, and in book 4 of the *Epitome of Copernican Astronomy*, parts 2 and 3, that is, from page 499 to 530, teaches that the Sun is at the centre of the world and has a motive soul with a kind of bodily life, by which it is moved perpetually about its own axis. *For although this motion*, he says on page 514, *could be continued by some other means, yet the duration and perpetuity of this motion, in which the life of the whole world consists, is more correctly secured by the support of a soul.* He then says that the Sun emits from itself a species similar to the one a magnet emits, and through it grasps the other planets as if by a hand; and while it turns in rotation about its own axis, it carries the other planets around. It does so, however, in such a way that when that magnetic virtue falls on the friendly part of the planets, according to the disposition of their magnetic fibres, it draws them towards itself, and they become perihelial. But since the planets have a power of holding themselves in a position parallel to the one they first acquired at the beginning with respect to their situation in the universe, it comes about that gradually their hostile part, the face contrary to the Sun, is turned towards it; and so they are driven off by the Sun's magnetic species or quality and become aphelial — just as a magnet draws to itself the friendly part of a magnetic needle and drives off the hostile part. Finally he says that in the other planets there is a certain inertia towards motion, and a resistance that is greater the farther they are from the Sun. Thus he teaches that the Sun is moved from within and the other planets from without, namely by the Sun — but by no means by an Intelligence (page 508). Bullialdus refutes these fictions of his, ingenious as they certainly are, with many arguments in the place cited. Yet the same Kepler, in the *Hyperaspistes*, page 6, admits that the Christian schools ascribe these motions of the heaven to Angels; and, on

page 7, that according to Tycho the Star of the Magi and the comets were moved either by a Genius or by an innate knowledge.

[Margin: What of Tycho?] Tycho seems equally to belong here. In volume 2 of the *Progymnasmata*, page 268, he says: *It is therefore proved, even from these observations alone of the two ethereal comets, namely those of the years 1577 and 1585, on account of their motion peculiar beyond the other planets, that no orbs really exist in the aether, nor does the heaven itself consist of hard and impervious matter; but that the stars themselves possess a certain natural and innate — or rather divinely implanted from the beginning, and perpetually preserved — knowledge of regular motion, by which, driven or supported by no orbs, they complete their courses most perfectly and most constantly.* But from these very words, and from what was said in the preceding section, chapter 8, number 4, it is clear enough that he is to be assigned to the second class, which teaches that the stars are moved by a soul that is not only sensitive but also intellective; and Kepler too belongs there in part. [Margin: What of Suárez and Raynaudus?] Suarez [Francisco Suárez], moreover, *Metaphysical Disputations* 29, section 1, number 16, and earlier in disputation 18, section 7, number 36, nevertheless concedes, in the course of disputation, that the motion of the heaven can be attributed to its own incorruptible form; and Theophilus Raynaudus [Théophile Raynaud], in his *Natural Theology*, distinction 2, q. 1, art. 1, says that the opinion of those who assert that the heaven or the stars are moved by an intrinsic form of their own is not to be condemned as rash.

II. [Margin: 2nd opinion: on a moving soul.] The second opinion was that of those who said that the heavens and the stars are indeed moved by their own form, but that this form is an intellective soul, or else a sensitive and vegetative one. I have already listed these individually in Section 1, chapter 8, from number 1 to 4, and so we do not repeat them. [Margin: 3rd opinion: on God as mover.] The third opinion, then, was that the heavens are moved by God himself, immediately. So judged Albert the Great, on 2, distinction 14, art. 6; Alpetragius [al-Biṭrūjī], *On the Physical Cause of the Celestial Motions*; and, if you believe the Conimbricenses, Ptolemy himself; and Leonardus Lessius [Leonard Leys], in the book *De Providentia*, from number 20 on. This was also judged probable by

Gabriel, on 2, d. 14, the single question, and Gregorius Ariminensis [Gregorio da Rimini], on 2, d. 8, q. 3. For although Abulensis, on chapter 22 of Exodus, q. 5, denies that local motion can be produced by God immediately — both because it is the act of a being in potency, and something imperfect, and because he would then move in an instant — it is nevertheless an error to deny this, as St Thomas teaches, part 1, q. 105, art. 2. Whether the supreme heaven is moved immediately by God, according to Aristotle, I shall say at number 11. Nor, if it is denied that God immediately produces the motion of the supreme heaven as a particular cause, will it follow that there is an infinite regress among movers and causes, or that the means of demonstrating the divine existence is taken away. For it suffices that one can infer from creatures and effects that

God exists as a universal cause, who nonetheless concurs, by an immediate concurrence, with the efficient secondary causes.

[Margin: The existence of God is demonstrated by a new argument.] There are, moreover, other ways of demonstrating the divine existence, and the one that strikes me as the most evident of all is this. We judge evidently that a supremely perfect being is possible, one having all the simply simple perfections that are compossible (for if some perfection is mixed with imperfection, or conflicts with another that is more necessary and more to be chosen, we are not speaking of it). But among the other simply simple perfections, which conflict with no such perfection, is necessary existence — that is, so to exist that it never can, and never could, not exist — as any intellect that is not badly disposed judges. Therefore, if such a being is possible, it also exists in fact, since that perfection includes not the mere possibility of existing but actuality, and indeed necessary actuality. And in this case alone the argument from the possible to being, that is, from being able to be to actually being, is valid. Many years afterwards I found this argument indicated, though in a different form of words, by Renatus Cartes [Descartes] in the *Principles of Philosophy*, part 1, number 14.

[Margin: Some have said that the heaven moves by chance.] Let this be said against the atheists. But those who wish to show God from the motion of the heaven are diametrically opposed by those who said that the heaven moves by chance, namely Democritus and Epicurus.

III. [Margin: 4th opinion: that they are moved by Angels.] The fourth opinion, and the most common, is that the heaven and the stars are moved by Intelligences, or Angels, as assisting and immediate efficient causes, not as souls informing the heaven; and so that they are moved by an extrinsic principle, but a created one. In this opinion are all those already enumerated in Section 1, chapter 8, from number 5 on, and those who treat this controversy expressly. [Margin: Authors of the 4th opinion.] They are: St Thomas, part 1, q. 70, art. 3; q. 6 *De potentia*, art. 3; opuscule 10, art. 3; opuscule 11, art. 2; and *Contra Gentiles* 2, chapter 92, with Ferrariensis at that place. Likewise the Scholastics almost generally on 2, dist. 14, especially St Bonaventure, art. 3, q. 2; Scotus, q. 1; Durandus, q. 2; Argentinas [Thomas of Strasbourg], q. 1 and 2; Ariminensis on 2, d. 1, q. 1; Capreolus, dist. 9, q. 1, art. 3; Albertus, *De quatuor coaevis*, part 1, q. 4, art. 26; Nicolaus Cusanus [Nikolaus von Kues], book 7 of the *Exercitationes*; Soncinas, *Metaphysics* 12, q. 36; Iandunus, *De substantia orbis*, q. 2, 13 and 14, and *De caelo* 2, q. 92. Among the more recent: the Conimbricenses, *De caelo* 2, chapter 5, q. 5; Rubius, at the same place and *De caelo* 1, chapter 2, q. 8; Toletus [Francisco de Toledo], *De caelo* 2, chapter 5; Suarez, *Metaphysics*, disputation 18, section 7, number 36, and d. 35, section 1, number 20; Pererius, book 2 on Genesis, q. 5, and *Physics* book 7, ch. 7, q. 2, who says that it was handed down as if from hand to hand by the philosophers and received by the theologians; and Bubalus, *De Angelis*, q. 1, diff. 2, art. 15, who judges the opposite dangerous; Arriaga [Rodrigo de Arriaga], the single disputation on the

heaven, section 5, number 64; Hurtadus, disputation 2 on the heaven, section 4; Oviedus, the single controversy on the heaven, point 1, number 7; Mastrius and Bellutus [Bartolomeo Mastri and Bonaventura Belluto], disputation 2 on the heaven, q. 4, art. 3; Georgius Polaccus [Giorgio Polacco], in the *Anticopernicus*, assertion III; Aversa, q. 34 of the *Physics*, section 7; Io. Antonius Delphinus [Giovanni Antonio Delfino], Franciscan, the opuscule *On the Celestial Orbs*, from page 80; Io. Poncius, disputation 22 of the *Physics*, q. 9; Amicus, treatise 5 on the heaven, q. 6, doubt 2; and Chiaramonti, book 2 *De Universo*, chapter 17.

[Margin: Notable sayings of St Thomas.] But I am glad to record the view of St Thomas, who says, in q. 6 *De potentia*, art. 3: *But it is the teaching of the Faith that Angels move locally by their command not only the celestial bodies but also other bodies, God ordaining and permitting.* He had reported the opinions of the philosophers who granted the Angels the motion of the heavens but denied them that of other bodies. And in opuscule 10, art. 3: *But that the celestial bodies are moved by a spiritual creature, I do not remember having read denied by any of the Saints or the philosophers.* Finally, in opuscule 11, art. 2: *But it seems to me that it can be proved demonstratively that the celestial bodies are moved by some intellect, either by God immediately or by the mediation of Angels. But that he moves them by the mediation of Angels befits the order of things, which Dionysius asserts to be infallible, that lower things are administered by God through intermediaries according to the common course.* That this was the view of the ancients was taught by Trithemius in the book *On the Seven Intelligences that Move the World*, whose words I have already reported in book 7, section 1, chapter 1, where I listed many things, not unworthy of a learned reader, about the seven spirits that move the seven planets.

VNICA CONCLVSIO.

Single Conclusion.

Although it cannot be demonstrated either metaphysically or mathematically, but at most physically or morally, that the heaven or the stars are moved by Intelligences, yet, in view of authority both sacred and profane, it must be said that they are moved by Intelligences.

IV. The first part of the Conclusion is evident, because neither from the principles of metaphysics nor from those of mathematics can a necessary connection be deduced between the motion of the heaven or the stars and the Intelligences — whether their motion is considered according to its substance or its essentials, or as to its accidental perfections: especially the most perfect order and harmony, that is, the uniformly difform anomaly, and the infallible rules that they keep in their periods and revolutions, and their perpetuity and constancy over so many centuries. For it is not repugnant either to the principles of being as being, or to terminated quantity as such, whether continuous or discrete, that God could make bodies which are moved in this way from within, by a virtue and qualities connatural to them and implanted by God at the beginning of the world, as we said at number 1 in reporting the first opinion; and that they are moved by such

motion for the good of lower things in such a way that this very thing is their good — to exert their virtue and communicate their influences to others. In the same way it is the perfection of a master to teach others, and of a physician to heal others; granted that this is an extrinsic perfection, it nevertheless reveals an intrinsic one. For what some have attempted against this is too slight to need a reply: as when they say that circular motion is reflexive upon itself, and that reflexion comes from a soul; and that every mover presupposes an immobile part on which it leans, as when an animal leans on its foot — for what will they say[26] of the fins of fishes and the wings of birds? — or when they say that the same thing cannot be at once in potency and in act, and that therefore every mobile thing must be moved from without.

Nor is a moving Angel necessary in such a way that its existence could be demonstrated from this. For either its existence is known from elsewhere, and so it is not necessary on that account; or it is unknown, and so the thing about which the question is raised here, as the less known, is not shown from what is better known. [Margin: Whether the existence of Angels is demonstrated from the motion of the heavens.] Moreover, we have already shown with many arguments in the treatise *On Angels*, while we were publicly professing theology, that there is no natural middle term by which the existence of Angels may be demonstrated. For all effects either include a determination to moral fault or to falsity, and can then be attributed to separated souls; or they do not include it, and can be attributed either to those same souls or to God. And so on, reasoning through the rest.

[Margin: 2nd part of the Conclusion.] The second part, about physical or moral demonstration — conceded rather than asserted — is proved as follows. On the one hand, we have no indication in the stars, or from the stars, of animal operation, since neither organs nor anything similar appear in them. On the other hand, the admirable harmony of the celestial motions, and their proportion and order, constant through so many centuries — far greater than in the humours of the human body, indeed than in any machines devised by human skill — is an argument for a soul or mind that constantly preserves and directs such motions. Therefore it is physically, or at least morally, evident that the heaven or the stars are moved by some mind, which is nevertheless not properly their soul. This holds all the more since there is such variety and subtlety in the motions of the planets that not even the most skilled of the astronomers have so far fully comprehended it. Add to this that we have it by sufficient induction that whatever is moved locally is moved in order to be better off in a different place, and that to be moved within its own place is proper to living things; but neither of these fits the heaven or the stars.

The third part is confirmed, first, from the multitude of autho- rs of both classes; and then from Sacred Scripture. For many Fathers interpret as referring to the Angels the text of Job 9, *Under whom they stoop that bear up the world*, and

[26]the print reads "d-" / "cent", the i not printed

Job 26, *The pillars of heaven tremble*, and 38, *When the morning stars praised me, and all the sons of God shouted for joy*, and the text of Matthew 24, *The powers of the heavens shall be moved*. Lastly, St Dionysius (*Celestial Hierarchy*, chapter 5), St Augustine (*On the Trinity*, book 3, chapter 4) and St Gregory (*Dialogues*, book 4) teach that it belongs to the sweetness of divine providence to move and govern lower things through higher ones, and corporeal things through spirits; and by ascribing this motion to the Angels all difficulties are more easily avoided. Nor, as Lessius seems to fear, is it absurd that some of the Angels should be held perpetually — that is, until the end of the world — occupied in this ministry, so that they can neither ascend to the Empyrean nor descend to the earth to men. For they obey God most willingly, and their beatitude is not diminished by it; and if it were expedient to send some of them to earth — say, to adore the Most Holy Sacrament of the Eucharist more closely, or to instruct someone in some account of celestial motion — it is very easy for God to put others in their place.

[Margin: The objections of Kepler resolved.]

V. But now the objections of Johannes Kepler must be resolved, by which, in his *Epitome of Copernican Astronomy* from page 508, he contends that created Intelligences do not move the planets, but that the planets are moved by the Sun with a certain material and natural necessity. For, he says, solid orbs cannot be admitted, since it has been shown that the heaven of the planets is fluid; and without solid orbs a created Intelligence cannot move the planets. First, because a mind lacking animal and locomotive power cannot produce motion in a body other than its own by a mere nod, or by the desire or command of its will. Second, because if a Mind were the mover, it would certainly move the planets in a perfect circle, which has mental beauty and perfection; but from astronomical observations properly treated we are convinced that the path of a planet is not a perfect circle but either an ellipse or a similar figure, which savours rather of the nature of the steelyard [statera] and of material necessity than of the conception of a mind. Again, although the tempering of the extreme motions — that is, of the slowest and the fastest in each planet — is most exquisitely harmonious, and the work of the supreme and adorable creating mind, yet the lengths of the periodic times have no mental beauty, because they do not have expressible or rational proportions, such as double, triple and so on, but inexpressible or irrational ones that thus run on to infinity; nor are the times of a single period gathered from equal delays [morae], but from unequal delays in different parts of the circle, according to the ratios of the steelyard. Lastly, no place can be assigned in which the Intelligence might reside and from which it might recognise the path along which it is to direct the planet. Not at the centre of the circle, or at the centres or foci of the ellipse, for in the ethereal air those places do not differ from other points; nor from there could the mind perceive whether the planet, at so great a distance, was travelling along the path it must, unless you give it eyes, or a cord to which the planet is tied and led round. For it is not enough to have a mental idea of

the planetary orbit: some instrument is needed by which the real course of the planet, having a definite quantity, may be carried into execution. Nor can the Intelligence be placed on the circumference of the orbit. For either it will rest at one point — and the argument just made recurs when the planet is at very distant points — or it will move from place to place, as the soul does with the body. But since this mind lacks a body, and is not of itself mobile or capable of position, it will have no means by which to measure its distance from the centre of the world (since this centre lies outside the centre of the planetary orbit), or to keep its position in relation to that centre. Yet Kepler grants that the figure of the planetary orbit and the periodic motions are the work of the creating Mind, that is, of God. This is precisely Kepler's reasoning, and it seems to me as much the duller as it seemed to him the sharper: first, because it assumes as granted certain things that cannot be granted without injury and discredit redounding upon the Intelligences; second, because it entangles reasons that contradict one another. It will be worth the effort, however, if I put these arguments into form and blow them away.

[Margin: First argument from Kepler.] [Margin: Proof of the [?]]

VI. The first argument is of this kind. *If a Mind or created Intelligence moved the planets, it would move them in a perfect circle, and in such a way that the periodic time of a planet would have a rational proportion, one that can be gathered from equal delays.* For such a figure and motion have a beauty and perfection worthy of a mind and befitting an Intelligence. But the motion of a planet does not take place in a perfect circle, nor does its periodic time have a rational proportion, nor one gathered from equal delays. Therefore …

[Margin: First reply.]

I reply, first, by denying the major premise, for there is no necessity in such a proposition. The circle is not the only perfect figure — especially with respect to the end to which the motion is ordered: the ellipse and many other figures are perfect too. Nor are only the proportions expressible by us beautiful, but also those that are inexpressible by us, yet rational to God, who ordained them, and expressible at least to his divine Word, to whom he speaks all things, finite and infinite. Nor is it necessary that he should have communicated the idea and knowledge of them distinctly to the Angels: it is enough if he commanded them to move the planets along such a determinate path through the ethereal air, with such a velocity, and within such a time to bring them round to the same, or nearly the same, point — whatever proportion finally arises between the parts of that motion, or between the whole period and the period of another planet.

[Margin: Second reply, *ad hominem*.]

I reply, second, by turning the argument back, thus. An imperfection of figure and motion that is unbecoming to an intellectual nature, and unworthy of a created mind because of the perfection of such a nature, is much more unbecoming to the divine nature and unworthy of that supreme Mind. But the figure and periodic motion of the planets are of this kind, on your own

account, O Kepler. Therefore they are not the work of the divine mind — which it is impious to say, and not even you say it; on the contrary, you have expressly professed the opposite. Nor will you escape by saying that that figure and motion are not immediately from God but from the Sun, which moves the other planets. For since the Sun does not determine it freely but by natural necessity, this whole determination is in the end from God, and it is not to be ascribed to him if it contains an imperfection unworthy of God as its author.

[Margin: Second argument from Kepler.]

VII. The second argument is of this kind. The motion of the planets takes place along an ellipse according to the ratios of the balance and the lever — that is, according to a material necessity arising from the nature of steelyards — rather than according to an intellectual ratio or a voluntary purpose. But if they were moved by an Intelligence, they would not move so. Therefore, etc.

[Margin: First reply.]

One could reply by denying the major premise, if the discussion concerns the ratio intended per se and primarily by the motive faculty of the planets. For granting that some similarity or analogy were conceded between such a motion and the motions produced by a steelyard and a lever, it is still not worthy of God that he should have willed to represent this analogy per se and primarily; nor is that text of Wisdom 11, *He has disposed all things in weight, number and measure*, to be confined to these mechanical narrows, but extended to higher ends and to the determinate proportions of means to their ends.

[Margin: Second reply.]

I reply, second, granting the major, by denying the minor. For the knowledge of such ratios could have been infused into the moving Angels, so that they would balance the planets and move them in such a way that that analogy would be preserved — as being better suited to us, who are of grosser understanding — and yet not contrary to the end of these motions.

[Margin: Third argument from Kepler.]

VIII. The third argument is as follows. If an Intelligence moved the planets, it would need some body by which to perceive by what path they were to be directed, and how their distance from the centre of the world was to be preserved in such motion. But the Intelligences have no such body: for there are no solid orbs of the planets by whose motion that path and distance might be kept; nor have they cords or similar aids by which to lead the planets round; nor are they forms informing or animating the planets — or, if they were, the planets still contain no sense organs through which the path and distance already mentioned could be perceived. Therefore …

[Margin: Reply.]

I reply, first, by denying the major, as being uttered unworthily against the most perfect mode of understanding with which the Angels are endowed. For they understand all sensible things without sensations, and all corporeal motions, and the figure that those motions can describe, through impressed species alone and divinely infused ideas — and far more perfectly indeed than

Kepler understands those ellipses and librations of his. Unless he is so dull as to think that an Angel, lacking eyes, hands and so on, does not understand those figures and ratios of motions, and the intervals between the planets and the centre of the world, which Kepler himself believes he understands — although not immediately through the senses but deduced by reasoning from observations; or else that the Angel does understand them, but cannot, without corporeal organs, impress upon the planets such a motion as shines forth in their intelligible Ideas:

What could be more stupid than this statement, or this thought? Could a painter be found who would draw a perfectly straight line and a perfectly round circle without ruler and compass, and yet an Angel will be unable, without any corporeal instrument, to push a planet, or lead it round, along that orbit along which Kepler's Sun — and its soul, which is neither intellectual nor sensitive — drives the planets round by some blind direction? But now I am ashamed, in Kepler's name, and weary of lingering any longer over refuting these frivolous trifles; and it is better to dispatch three other questions belonging to this chapter.

De Modo, quo Intelligentiæ Cælum vel Sidera mouent.

On the Manner in which the Intelligences Move the Heaven or the Stars.

IX. It is commonly asked whether the Intelligences move the heavens — or, more generally, whether Angels move bodies — by intellect and will alone, or rather through a power distinct from both of these. For Averroes, Durandus, Bassolius, Argentinas, Capreolus, Soncinas, Parisiensis, Hervaeus [Hervaeus Natalis], Aquarius, Victoria [Francisco de Vitoria] and certain other Thomists — whom the Conimbricenses report (*On the Heavens* 2, chapter 5, question 7), and Amicus (treatise 5 *On the Heavens*, question 6, doubt 6) — thought that the intellect and the mere desire, or command, of the will are sufficient; and among our own authors they are followed by Vasquez (disputation 102, chapter 5), Delrius [Martin Delrio] (*Disquisitiones magicae* 2, question 6) and Molina (part 1, question 54, article 5). St Thomas strongly favours them in the same place, and in Quodlibet 2, article 2, in Opusculum 11, articles 3 and 13, and in *De malo* question 16, article 1, reply to 14. So does Aristotle (*On the Soul* 3, text 49), where he said: *Both of these, then, are motive with respect to place, intellect and appetite.* For it seems pointless to multiply another power, especially in a purely intellectual nature, in which it is fitting that what is dispersed among lower beings should be united, and that all its powers should be purely intellectual.

[Margin: The power of an Angel to move in place is distinguished from its intellect and will.]

On the contrary, however, it has been taught more correctly that the power by which Angels move themselves and bodies in place is distinct from their intellect and will — so taught Scotus (on Book 4, distinction 10, question 7, and on Book 1, distinction 45), Henricus Gandavensis [Henry of Ghent], Maironus, Aureolus, Caietanus, Godophredus and others, whom the Conimbricenses and Amicus, cited above, adduce and follow; Suarez (*Metaphysical Disputations* 35,

section 2, number 21, and *De Angelis* book 4, chapter 29), Raynaudus (*Theologia naturalis*, distinction 4, question 3, article 4), Ruvius (*On the Heavens* 2, chapter 5, question 11), Tannerus (part 1, disputation 5, question 5, doubt 1), Meratius (disputation 21 *De Angelis*) and Alarcon (disputation 6, chapter 8). For both the objective concept of these powers and their proper object are different; nor can the intellect elicit any operation other than intellection, nor the will any other than volition, insofar as each is such a power; but neither of these is local motion, or the production of the impetus that effects it. Otherwise an Angel could move in an instant, and to any distance, and any body however large, because an Angel can understand and love these things. The intellect, therefore, by directing and proposing, and the will, by commanding, can only be the moral cause of this motion; an executive power is needed, to which the command is given, as St Thomas also taught (*De potentia* question 6, article 7, and Quodlibet 9, article 10). Indeed, in part 1, question 25, article 1, he teaches that the divine power carries the character of a principle that executes what the will commands and what knowledge directs. When, therefore, he teaches that God and the Angels move by intellect and will alone, he must be understood to exclude a motive power that is really distinct, or one that adequately includes bodily organs, such as exists in animals. I suppose, moreover, from what I have said elsewhere in the treatise *On Angels*, that the Angels impress a certain quality which carries the mobile body from place to place, which is called impetus, and from which motion follows immediately — as Molina also teaches (part 1, question 110, article 3), and Vasquez (disputations 128 and 218) and Tannerus (above, doubt 2) — at least when the mobile body is separated from the Angel. Granted that Suarez (disputation 35, section 6, number 24, and *De Angelis* book 4, chapter 31) and Amicus (above) teach that only motion is produced by them, at least when the Angel is immediately present; and this holds whether that impetus is spiritual, as coming from a spiritual principle, or rather corporeal, as ordered to moving a body and received in a corporeal subject.

An & vbi quieſcant Intelligentiæ Motrices.

Whether, and Where, the Moving Intelligences are at Rest.

X. It is further asked whether the Intelligences, while they move the heaven or the planets, are at rest — and in what part of the heaven — or rather fly round together with them. That the Intelligence resides in one determinate place of the heaven, and from there impresses motion on the heaven, to which it is immediately present, the motion being afterwards diffused into the other parts of the heaven, was taught by Aristotle (*Physics* 8, last chapter, text 84, and *On the Heavens* book 2, chapter 2), St Thomas (part 1, question 52, article 2), St Bonaventure and Scotus (on Book 2, distinction 2, question 5), the Conimbricenses (*On the Heavens* 2, chapter 5, question 8), Tannerus (volume 1 of the *Theology*, disputation 5, question 5, doubt 2) and Amicus (treatise 5 *On the Heavens*, question 6, doubt 6). The Peripatetics teach that this part is on the equator, where the motion is fastest, and in the east, where the motion

begins. Others, however, draw a distinction. They say that the Intelligence which moves a whole heaven, or one entire heaven — say, the primum mobile — rests in one determinate part of it, but that those which move the planets are carried along with the motion of the epicycle, so as to impress a different motion on it and on the planet. So Bartholomaeus Mastrius and Bonaventura Bellutus (disputation 2 *On the Heavens*, question 4, number 148), granted that they say Scotus considered it unfitting for Angels to run round and be moved with the motion of the heaven.

[Margin: The Angels that move the planets are moved along with them.]

But I judge that one should answer otherwise. For, speaking of the planets: since they move in a fluid aether, as was said in Section 1, chapter 7, number 21, it is consistent that the planets are led round by the Intelligences. For the Intelligences are not everywhere, nor can they produce impetus or motion in a body enormously distant, as I suppose from Saints Damascene (*On the Faith* 2, chapter 3), Ambrose (*On the Holy Spirit* book 1, chapter 10), Chrysostom (Homily 3 on Hebrews) and Gregory (*Moralia* book 2, chapter 2); for their place is circumscribed and limited, and their power finite. And this conforms with Sacred Scripture, if that text of Ecclesiastes 1 — *The Sun rises and sets, and returns to its place, and being reborn there it circles by the south and turns towards the north; surveying all things round about, the spirit goes on and returns to its circuits* — is understood of a Spirit, that is, of an Intelligence moving the Sun, with St Thomas (opusculum 10, article 6). Pineda and Lorinus, on that passage of Ecclesiastes, do not reject this, although they also bring forward other interpretations; nor indeed does St Jerome. For since he grants that a spirit and mind driving the Sun can be understood there, and elsewhere censures Origen for granting a soul to the stars, the text seems capable of being taken of an Intelligence that does not inform the Sun but moves it from outside. This being posited, if Sacred Scripture is taken literally, as it can be, it can be sufficiently confirmed from it that the Angel who moves the Sun himself also goes round, and accompanies the Sun that he moves. I later saw the same opinion, about Angels carrying the planets round, defended by Io. Antonius Delphinus in a truly learned little work *On the Celestial Globes*, page 80, and in Arriaga (single disputation *On the Heavens*, number 54). But if we are speaking of the heaven of the fixed stars, whether it is moved by one Intelligence or by several, it can be granted that they reside in a single place of the heaven. But if there is one, and any point of the heaven on the equator is rising with respect to some horizon, it will be necessary to fix on some particular region — say Palestine — on whose eastern horizon that Angel would be; or else, to avoid this singular position and the difficulty of moving so vast a machine, this could have been done by several Intelligences arranged in a circle. For the rest, it is not for our weakness to divine about these things; and we must from time to time remember that divine rebuke in Job 38: *Do you know the order of heaven, and will you set down its reason on Earth?*

Quot ſint Intelligentiæ Motrices Cælorum & An inter eas DEVS ?

How Many Moving Intelligences of the Heavens there are, and whether GOD is among them.

XI. There were some, left unnamed by Fracastoro (*Homocentrica*, section 1, chapter 7), who said that all the celestial orbs are moved by a single Intelligence; among them Alpetragius is counted. Just as all the vital operations of one body are carried out by a single soul — especially since the heaven resists no motion once impressed, nor is it necessary that the contact of the angelic power be immediately applied to all the parts to be moved; it is enough for it to be present to one part, from which the motion is diffused into the others. But, as the Conimbricenses note (*On the Heavens* book 2, chapter 5, question 8), and Mastrius and Bellutus (disputation 2 *On the Heavens*, question 4, number 147), it is the common opinion of the theologians, on Book 1, distinction 37, that the sphere of angelic activity is bounded by definite spaces, and the Angels' power is limited, so that they cannot move one whole element from its place — much less impart with a single impulse such varied and almost contrary motions to so many and such vast heavens, really distinct from one another, if solid orbs were posited. But since the heaven of the planets is fluid, and is not itself moved in such a way that the planets are moved with its motion, it is clear enough that it follows from this that, besides one or more Intelligences moving the sphere of the fixed stars, there are at least seven others for as many planets. And this fits very well with the order and distinction of offices — just as individual men, provinces, cities, and perhaps churches each have their own Guardian Angel, as Albertinus teaches in his book *On the Guardian Angel*.

Furthermore, Aristotle (*Metaphysics* 12, chapter 8, from text 47) posits as many moving Intelligences as there are partial celestial orbs, adding that each Intelligence is so commensurate with its own orb as regards motive power that it cannot move a higher sphere. This the Conimbricenses nevertheless refute, referring the reader to Capreolus (on Book 2, distinction 3, question 1, article 3) and to Maior (on Book 2, distinction 14, question 2).

[Margin: Is God among the moving Intelligences?]

It is, moreover, disputed whether Aristotle counted God among these Intelligences, as the immediate mover of the highest heaven — as the Conimbricenses (*On the Heavens* 2, chapter 5, question 6), Piccolomineus, Pendasius, Ruvius, Aversa and Amicus, with Gregory (on Book 2, distinction 1, question 1, article 1), hold — or rather placed him outside and above this number, inasmuch as he does not move that heaven except through some created Intelligence, as St Thomas (*Contra Gentiles* 1, chapter 13) and the Thomists with him hold, and likewise Iandunus (*Metaphysics* 12, question 17), Abulensis (on Exodus chapter 23, question 3), Scotus (on Book 1, distinction 2, question 1, and distinction 8, question 5, and Quodlibet 7), Contarenus (*On the Heavens*, in the question on this matter), Suarez (*Metaphysical Disputations* 35, section 1), and Mastrius and Bellutus (disputation 2 *On the Heavens*, question 4, article 4). And indeed, since Aristotle thought that God necessarily acts outwardly (as St Thomas teaches

in *De malo* question 16, article 10, and on *Metaphysics* 12), and so exerts his whole effort, and moreover that God is of infinite power, it would follow from Aristotle's reasoning (*Physics* 8, texts 78 and 79) that God moves with infinite velocity and in no time; or, if anything resisted him, that a finite power could prevail over or equal an infinite one — both of which are absurd. Furthermore, in *Metaphysics* 12, text 36, he taught that the first mover moves as lovable and desirable, inasmuch as the created Intelligences, contemplating his supreme goodness in communicating being to themselves and to other things, strive to make themselves like him by moving the heavens, and through their motions and influences to communicate very many goods to the lower natures. Hence God moves the heavens in the manner of a good and an end, or also of an Idea — without, however, excluding the effective concurrence by which, as universal cause, he concurs immediately in all effects. And so Aristotle must be understood in the same place, text 38, where he says that the primum mobile is moved by the first Intelligence, and in text 43, where he counts as many Intelligences, the first not excluded, as there are orbs.

Therefore, since he had learned from Eudoxus that the whole inequality of the planets in their motion could be demonstrated by 25 [?] orbs, and from Calippus by 33, Aristotle himself, believing that the heaven consists of solid orbs, added 22 other orbs, ἀνελίττοντας [Greek: anelittontas, "unrolling"], that is, Revolving orbs. The purpose was that each lower orb should be freed from the drag which, because of the contiguity of the surfaces, it would otherwise have suffered from the one above it, by means of an interposed Revolving orb, straining in the opposite direction in an equal time and by that counter-effort presenting the appearance of an orb at rest; so that the lower or inner orb, resting on that orb as on one immobile, would complete its own proper period.

[Margin: The Aristotelian number of the Intelligences.]

So Kepler explains it, in his work on Mars, chapter 2, and in the *Epitome of Copernican Astronomy*, book 4, page 505; but in those places he wrongly says that the movers established by Aristotle are 49, or according to Calippus 53 or 55. For below, in Section 3, chapter 5, number 5, we shall show that in Aristotle's mind they are 55, and with the primum mobile 56; but under another hypothesis 47, and with the sphere of the fixed stars 48; and we shall expose the errors of many concerning this Aristotelian number. Again, in Section 3, chapter 7, we shall treat the 70 solid orbs that Fracastoro devised in the *Homocentrica*, composed of *circitores*, *anticircitores*, *circumducentes*, *contravecti* and so on.

[Margin: A conjecture on the number of the Intelligences.]

XII. Further, if I were permitted to settle anything about this number by some conjectures, I would say that, besides the Intelligences — either 4, or 12, or 24 — that move the highest orb of the fixed stars, there are seven principal Intelligences, assigned to revolving the seven planets; and that these are those seven Spirits of whom we spoke, with Trithemius and Cornelius à Lapide, in Book 7, Section 1, chapter 1, setting out many things worth knowing, which it will help to re-read at this point. I would add, however, other, less principal

Angels, either for the less principal motions in altitude and latitude, or at least for driving round the companions one by one — two of Saturn and four of Jupiter. For I would by no means assign individual Angels to the spots of the Sun, which come into being and perish from time to time. But I fear that God and the Angels themselves, if it is right to speak so, may laugh at these efforts of ours, as of people who wish to investigate things that are above us.

CAPVT II.

Chapter 2.

De Inſtrumentis Motuum Cæleſtium, ſintne Orbes ſolidi, an meri Circuli in fluido æthere deſignabiles, ijque Excentrici cum Epicyclis, an meri Concentrici.

On the Instruments of the Celestial Motions: whether they are Solid Orbs, or mere Circles that can be designated in a fluid aether; and whether these are Eccentrics with Epicycles, or mere Concentrics.

I. An admirable variety of motions has been detected in the planets by observation — indeed one as manifold as we indicated in Book 7, Section 1, chapter 7. Yet a threefold variety, corresponding to the threefold dimension of bodies, was more manifest to the ancient physicists and astronomers: namely, in longitude, in latitude, and in depth or altitude. But because, of these, the variation in altitude was not evident to all, or was seen not as real but as apparent, arising from some deception of our sight or from a difference in the interposed medium, two very ancient sects arose from it.

[Margin: Who the Eccentricists and Concentricists are.]

One was that of the Eccentricists, who said that the motions of the planets are carried out by orbs having their own centre, different from and distant from the centre of the World, together with smaller orbs set into the larger ones, which they called epicycles; by their help they explained the inequality in motion of longitude and latitude, and also of altitude. The other was that of the Homocentrists or Concentricists, who asserted that these motions are completed by orbs concentric with the centre of the World, so that the planets in reality always kept the same distance from the centre of the World that each once had; but since their orbs moved on different poles, some orbs accelerating and others retarding, it came about that the motion of the planets, which in itself was equal, appeared unequal. What eccentrics, epicycles, concentrepicycles and so on are, and in what way they are imagined to be interwoven with one another, we have explained more than enough, with a diagram added — for the Sun in Book 3, chapters 19 and 21; for the Moon in Book 4, from chapter 25; and for the other planets in Book 7, Section 2, chapter 1 — and so we refer the reader there.

II. The authors of each sect, however, are further subdivided into two classes. Some thought that all these motions are made by solid orbs; others, without solid orbs — that is, in a liquid aether — whether by an intrinsic faculty

and principle implanted in the planets, or by an informing soul, or by an Intelligence that merely presides and drives the planets round along circles that can be designated, and described only in the imagination or the intellect. But this part of the controversy, concerning the solidity and fluidity of the heavens, setting aside the concentricity and eccentricity of the orbs, we have already examined sufficiently in Section 1, chapter 7. There, among the defenders of solid orbs, we placed not only Alfraganus with many Arabs, and Sacrobosco and Purbachius with their followers, but also, among the ancients, Eudoxus, Calippus and Aristotle, inasmuch as they attributed the inequality of motions to different orbs on different poles revolved upon them, which pushed forward or rolled back the orb in which the planet was set. Indeed, we placed there Anaximander too, of whom Plutarch says (*De placitis*, book 2, chapter 16): *Anaximander carries the stars round by the circles and orbs in which each star is set.* For neither Purbachius nor the Arabs were the first to introduce that solidity of the orbs. Rather, what Aristotle, with Eudoxus and Callippus, had tried to achieve through concentric orbs, and afterwards Fracastoro and some more recent writers through Homocentrics, he himself, following Ptolemy, achieved by stuffing Ptolemy's Eccentrics and Epicycles with solid matter. So neither Alfraganus nor Purbachius was the author of solid orbs as such, but of solid Eccentrics and Epicycles.

[Margin: Those who held solidity and eccentricity together.]

III. For Ptolemy and Hipparchus, and indeed the Pythagoreans, who introduced Eccentrics and Epicycles, or designed more perfectly those already introduced into astronomy, by no means bound them to the solidity of orbs. Either abstracting from solidity, or rather presupposing fluidity, they set out the motions of the planets by mere circular lines, and explained their hypotheses by bare circles, that is, by the peripheries of circles. This is how they, or at least Ptolemy, were judged by St Thomas (lecture 10 on *Metaphysics* 12), Piccolomineus in the *Theoricae Planetarum*, Vielmius (lecture 21 on Genesis), Martinengus in the *Glossa*, page 1023, Kepler in his work on Mars, chapter 2, and in the *Epitome of Copernican Astronomy*, book 4, part 2, Cabeo (on *Meteorologica* 1, text 38, question 2), and Blancanus [Giuseppe Biancani] in the *Sphaera*.

[Margin: Ptolemy does not support the solidity of the orbs, but rather their fluidity.]

But what need is there of a gloss, when Ptolemy's own meaning is plain and clear enough? For Ptolemy, in book 13 of the *Great Work*, or *Great Composition*, chapter 2, speaking of the manifold motion of the planets, especially in latitude, says: *Let no one think hypotheses of this kind too laborious when he considers the manifold artifice required in carrying them out. For it is not fair to put human things on a level with divine ones, and to seek belief about sublime things from examples of the most dissimilar things. For what is more unlike than things that always stay in the same state and things that are never constant to themselves, or than things that can be impeded by any cause whatever and things that cannot be impeded even by themselves?*

Rather, one must strive that hypotheses as simple as possible be fitted to the celestial motions; and if this does not succeed, at least such as are possible for us. For if by such hypotheses it follows that everything that appears in the heavens is accounted for, what wonder is it if this variety can befall the celestial motions? Especially since there is no nature there that impedes the motions, but one fitted by nature to yield to the natural motions of each globe, even if they seem contrary; so that all of them can pass through those simple bodies, spread wide and fluid, and show through them, or be seen through them. And this can go forward correctly not only in the circles but also in the spheres themselves and in the axes of the revolutions — whose variety, and the alternating diversity of their motions, it is so laborious and difficult for us to represent in constructed images and in models of Theoricae, that the motions seem to impede one another. In the heavens, however, that variety of motions does not impede itself in the least. One must not, therefore, judge the simplicity of celestial things from what can seem simple among us, since there is nothing among us that seems equally simple to all men. For if anyone wished to judge in that way, he will think nothing in the heavens simple — not even the stable and simple nature of the primum mobile itself, because something like it among men is not only difficult to find but altogether impossible. Judgement must therefore be passed not from these things but from the very nature and unchangeableness of the celestial motions. For in this way it will come about that all those motions appear simple, and indeed much simpler than the things that seem simplest among us, since we can conceive no difficulty and no labour in their periods.

Although Ptolemy, then, names spheres and axes, yet since he acknowledges the greatest possible simplicity of motions — indeed, through a single continuous line — and posits the planets as going through the substance of the aether, which yields and impedes nothing, who does not see that he favours the fluidity of the heavens rather than their solidity? And so he was understood by St Thomas (part 1, question 70, article 1, reply to 3), by Carthusianus (article 12 on Genesis), and by Kepler in the *Epitome*, page 504 — granted that there Kepler censures him for making the motion intrinsic and natural to the planets, for the divinity attributed to them, and for excluding every figure, image or model drawn from our own things. For Kepler thinks that by an ellipse, and by examples of the balance and the magnet and the like, the motions of the planets can be represented very well. But below we shall speak again of this simplicity of motions according to Ptolemy's mind.

Now we must come to the other part of the proposed question: namely, whether — in a solid or in a liquid aether — the motions of the planets can be carried out in the heavens, and explained on earth, by concentric orbs or circles alone; or whether Eccentrics, or equivalents of Eccentrics, are required.

[Margin: The first opinion asserting [?] concentrics.]

IV. The first opinion was that of the Homocentrists. Some of them thought the motions of the planets equal; others thought them unequal, indeed, but their distances from the centre of the world equal. Of these we may understand that saying of Plutarch (*De placitis*, book 2, chapter 16): *Anaximenes [holds] that*

the stars turn in the same way both around the earth and above the earth. Plato and the mathematicians [hold] that the Sun, Venus and Mercury are moved with equal motions.

[Margin: Anaximenes.]

But above all Eudoxus of Cnidus and Callippus of Cyzicus, who held with Plato that the celestial motions are circular, uniform and perpetual, tried to explain the whole real variety of the motions by orbs concentric with the centre of the universe; and Aristotle laboured at this very thing by adding other orbs, as is clear from Simplicius on books 1 and 2 *On the Heavens*, and from Aristotle himself, there and in *Metaphysics* 12. He was followed by Averroes, there, by Achillinus in his book *De orbibus*, and by the Conciliator [Pietro d'Abano] in Differentia 1.

[Margin: Eudoxus. Callippus. Aristotle. Averroes. Achillinus.]

Sosigenes, Hipparchus and Ptolemy rejected this opinion, calling in Eccentrics and Epicycles, and all astronomers thereafter followed Ptolemy. Yet a very few called it back into the light out of the rubble: namely Io. Baptista Amicus of Cosenza [Giovanni Battista Amico], in his opusculum *De motibus corporum caelestium*, published in 1537; Io. Baptista Turrianus [Giovanni Battista della Torre], and his heir in this, Hieronymus Fracastorius [Girolamo Fracastoro], in the *Homocentrica*, published the following year, that is, 1538; Lucillus Philalthaeus [Lucilio Maggi] (on *On the Heavens* 2, text 51); Andreas Caesalpinus [Andrea Cesalpino] (*Quaestiones Peripateticae*, book 3, question 4); and finally Io. Antonius Delphinus, a Franciscan from Casale Maggiore, in his book *De caelestibus globis et orbibus*. Alpetragius sides with them in many points in his celestial physics.

[Margin: Amicus. Turrianus. Fracastoro. Delphinus. Philalthaeus. Caesalpinus.]

Our own Bartholomaeus Amicus [Bartolomeo Amico], however, is mistaken (treatise 5 *On the Heavens*, question 5, doubt 2, article 2) when he counts among these authors all the astronomers who posit a fluid heaven, with the stars going in it like birds in the air or fish in the sea. For neither Tycho, nor Kepler, nor Boulliau, nor indeed any of the more recent astronomers who assert that the heavens of the planets are fluid, has used mere concentric circles in his hypotheses.

[Margin: Bartholomaeus Amicus's slip.]

[Margin: The second opinion posits eccentrics.]

V. The second opinion was that of the Eccentricists — that is, of those who, in setting out the motions of the planets, used circles, or ellipses, or quasi-circular spirals, having however a centre different from the centre of the world; or else used concentric ones, but carrying various Epicycles equivalent to eccentrics. The inventors of this opinion were the Pythagoreans, as Simplicius reports from Nicomachus (on *On the Heavens* 2). He also reports that Aristotle's opinion of concentric orbs was rejected by Sosigenes, because it could not

save the greater part of the motions, especially the stations, the retrogradations, and the elevations from the earth and the depressions — although he there describes no definite hypothesis of Sosigenes. Hipparchus, however, and Ptolemy throughout the *Almagest*, and after them Albategnius [al-Battānī], Alfraganus, Geber [Jābir ibn Aflaḥ], Thebit [Thābit ibn Qurra], Purbachius with his commentators, Copernicus in his work *On the Revolutions*, Maginus [Giovanni Antonio Magini] and Piccolomineus in their *Theoricae*, and from Tycho onward all astronomers, persisted in the same view. Those who argued for it, and asserted it with distinct arguments, were above all Maior (on Book 2, distinction 14, question 4), Petrus Alliacensis [Pierre d'Ailly] (question 13 on the *Sphere*), Christophorus Clauius [Christoph Clavius] (on chapter 4 of Sacrobosco's *Sphere*), and Bartholomaeus Amicus (treatise 5 *On the Heavens*, question 5, doubt 2). And these very things had long ago been confirmed by many indications by Pliny the Elder (book 2, chapters 15 to 17) and by Martianus Capella (book 8 of *De nuptiis Philologiae et Mercurii*, in the chapter *That the Earth is not the centre for all the planets*).

VNICA CONCLVSIO.

Single Conclusion.

The motions of the planets do not come about through circles concentric with the centre of the world, but through eccentric circles or quasi-circles, or through equivalents of eccentrics.

VI. The first argument could be drawn from the authority of almost all astronomers from Hipparchus down to this century of ours, who for seventeen centuries have held to this way of setting out the celestial motions, with very few resisting — and those few, if you except Fracastoro, unskilled in celestial observations. But in an astronomical question it is better to confirm our assertion by reasons.

[Margin: 1. Argument from the inequality of the distances.]

The first reason, then, is taken from the unequal distance of any planet from the centre of the earth: for within one period the planets are now farther from the earth, now nearer, now at some middling distance. We proved the Moon's unequal distance from the earth from the variation of the lunar parallaxes, in Book 4, chapter 14. Given its varying distances, a varying distance of the Sun from the earth necessarily follows, because of the astronomical connection that the Sun's distance has with the phase of the dichotomous Moon. This is clear from the problem of Aristarchus, and from our careful and legitimate use of it, often put into practice and set out in Book 3, chapter 7. So although the variation of the distances cannot be shown so evidently from the variation of the solar parallaxes, it can nevertheless be gathered from the Moon's distances and from the time between the appearance of the half Moon and the moment of quadrature. Once the varying distance of the Sun from the earth has been obtained, the distances of the other planets become known, because they have no less a connection with the Sun's distance than their motions have with the

Sun's motion, as can be established from what was said in Book 7, Sections 2 and 3, and Section 6, chapter 2. For equations agreeing with the true motions and the observed places of the planets cannot be derived except by supposing in their hypothesis a varying distance from the Sun and from the earth.

Moreover, in all seven planets a varying apparent magnitude is observed: in the luminaries, both outside eclipses and in eclipses, whose magnitude varies with their varying recession from the earth or approach to it. In Mercury, Venus and Mars, that variety too has been observed with telescopes, so that they appear sometimes full of light, sometimes gibbous, sometimes falcate, as we showed in Book 7, Section 1, chapter 2. Finally, how much larger Mars and Venus appear at perigee than at apogee we taught clearly in Book 7, Section 2, chapter 3, in the scholia; in Section 6, chapter 4, likewise in the scholia; and in chapter 10, likewise in the scholia. If the reader has understood these properly, no doubt will remain for him about that variety of apparent magnitude.

[Margin: The true cause of the varying apparent magnitude.]

Now the variety already mentioned cannot be put down either to vapours of the air, now thicker, now thinner, or to parts of the heaven, some denser and some rarer, as Fracastoro, Amicus and Delphinus dared to put it down. For, first, the most invincible argument drawn from the parallaxes stands against it: it shows the variation of distance, from which the variation of apparent magnitude necessarily follows. Besides, the same planets often appear larger when either there are no thick vapours in the air or the planets are far from them. And finally there is the wonderful agreement, in the proportion of the increase and decrease of this apparent magnitude, with a determinate situation relative to the Sun. For the three superior planets always appear very large in opposition to the Sun and in the acronychal situation, having become retrograde, and very small around conjunction with it; and Venus and Mercury always appear largest when falcate. And these phenomena are seen whatever the season of the year, and in whatever part of the zodiac. Besides, if the varying density of the heaven running beneath them were the cause of this variety, the magnitude of the fixed stars, and the clarity and brightness of the planets, would also change from time to time: for it would either be blunted by the density, or would seem more intense, the rays converging by force of refraction. Lastly, it would be necessary to multiply so many heavens, or celestial zones gliding beneath the seven planets, with denser and rarer parts — and indeed one heaven below the Moon. This would be done under no necessity, indeed with scarcely the thinnest probability, since it can be done far more naturally and simply by the alternating elongation of the planets from the earth and their nearness to it: that is, by the very means by which the inequality of motion in longitude is also said to come about. But if anyone is unwilling in this business to use Eccentrics or Concentrepicycles, and prefers concentric circles, now larger, now smaller, yet in such a way as to make them continuous, as the observations demand, then these circles, ever wider, will have to follow the form of a spiral gyration

rather than that of a perfect circle, returning into itself and concentric with the world.

[Margin: 2. Argument from the inequality of motion.]

VII. The second argument is taken from the inequality of the motions in longitude and latitude, which we have already described in Book 3, chapter 19, on the Sun; in Book 4, chapter 18, on the Moon; and in Book 7, Section 1, chapter 7, on the other planets; but above all from the inequality of the stations and retrogradations, on which see Book 7, Section 5, chapter 2. This argument makes our conclusion more probable; by eccentrics and epicycles, or by courses of lines equivalent to them, the variations already mentioned are set out better, and more neatly and beautifully according to the laws of geometry; and the physical cause of such inequalities is in some way placed before the eyes. Yet — to confess candidly what I think — it is not an evident argument. If the variations of the parallaxes and the alternations of the apparent magnitudes did not stand in the way, we could set out that whole change of speed and slowness by mere concentric circles, and by laws of motion that are numerical and logistic rather than geometrical, as we shall say below. It remains for us to dispose of the arguments of the Homocentrists.

[Margin: 1. Objection disposed of.]

VIII. First, it is objected against Eccentrics and Epicycles that the centre of the earth would not be at the centre of the heaven, or the centre of the heaven would not be at the centre of the world; and that this is absurd. The reply is to deny the major premise as regards the highest heaven, that of the fixed stars, and so too as regards the whole heaven of the planets, which is single and fluid and whose convexity is bounded by the concavity of the Firmament. If, however, the orbs are solid, the minor premise is denied when taken of any heaven whatever, and is granted only of the highest.

[Margin: 2. Objection.]

Second: simple motion upward and downward belongs to the elements alone, whereas to the celestial bodies belongs not straight motion but simple circular motion. But if they were moved by the force of Eccentrics and of an Epicycle, upward motion would belong to the celestial bodies. Therefore … The reply is to grant the major premise as regards motion upward and downward along a straight line perpendicular to the globe of the earth; in this sense the minor premise is denied.

[Margin: 3. Objection.]

Third: according to Aristotle, any heaven is perfectly spherical; but it would not be, if Eccentrics were posited. Reply: the major premise is granted and the minor denied. For if the heaven of the planets is fluid, it is single in reality and spherical with respect to the centre of the universe; and if it consists of solid orbs, every Eccentric orb is spherical as to its outermost surface, and every Epicycle with respect to its own centres.

[Margin: 4. Objection.]

Fourth: if Eccentrics and Epicycles existed, they could not be moved without penetration or splitting of the heavens, nor without rarefaction and condensation, since the less deep part would enter into the deeper; but this is unfitting. The reply is to deny the major premise. On the hypothesis of a fluid heaven the objection falls away. On the hypothesis of a solid heaven, too, the two orbs that are eccentric only in a qualified sense are not moved in such a way that the less deep part of one succeeds into the place of the thicker and deeper part, as the Averroists imagine out of inexperience. Rather, they are rolled proportionally, so that the thicker part of the lower eccentric always lies under the less deep part of the upper one, and the narrower part under the deeper, so that the orb that is eccentric simply has no motion other than that of the whole heaven of the planet.

[Margin: 5. Objection.]

Fifth: according to Aristotle, the farther a planet is from the highest heaven, which has a simple motion, the more motions it needs to attain its perfection; but on the hypothesis of Eccentrics and Epicycles the Sun has fewer motions than the three superior planets. The reply is to deny the major premise; for even according to the opinion of the Homocentrists, if they wish to save the phenomena of the Sun, fewer motions must be attributed to it.

[Margin: 6. Objection.]

Sixth: all the φαινόμενα [Greek: phainomena, "appearances"] of the heaven can be saved by concentrics and a plurality of motions, as Aristotle affirms (*On the Heavens* 2); therefore Eccentrics and Epicycles are multiplied in vain — especially since the two eccentrics carrying the planet's aux seem superfluous, and one seems to suffice, as Augustinus Niphus says. The reply is to deny the antecedent. For the motion upward and downward cannot be saved by mere concentrics; and, solid orbs being posited, both Eccentrics are necessary in the Ptolemaic hypothesis — not precisely to carry the aux, as Niphus thinks, but so that the whole heaven of the planet may have its own motion about the centre of the world. For in other hy- potheses these motions are arranged differently.

[Margin: 7. Objection, of Fracastoro.]

Seventh, Fracastoro objects. If the Sun is farther from the earth — or farthest — when it is at the beginning of Cancer, and least far when at the beginning of Capricorn, then either it will describe, in both places, parallels equally distant from the Equator, and so the Sun's greatest declination will not be equal on both sides, that is, 23½°. This is contrary to the observations: for the angle made at the centre of the world, or at the surface of the earth, by two lines, one ending at the periphery of the Equator and the other at the centre of the solar globe, will be narrower when the Sun is higher than when it is lower, as the laws of geometry and optics require. Or, if the Sun's greatest declination is equal on both sides, the Sun at the beginning of Cancer will necessarily describe a parallel more distant from the Equator than when it is at the beginning of Capricorn; and so, in an oblique sphere, the diurnal arc of the longest day will

not be equal to the nocturnal arc of the longest night. This too is contrary to experience and to astronomical observations.

The reply is that the Sun's greatest declination is indeed equal in both places, and that the diurnal arc of the longest day is unequal when compared with the nocturnal arc of the longest night in the same oblique horizon; but that this inequality is not perceived, because of the Sun's huge distance from the earth in both cases and its insensible parallax, which for us does not exceed 30″. Besides, the varying refractions, which hasten the Sun's rising and delay its setting, quite often compensate that inequality. Remember, however, that the Sun's apogee does not always lie at the beginning of Cancer.

[Margin: 8. Objection, of Fracastoro.]

Eighth: it would follow from Ptolemy's view that the epicycle of Venus is so large that it would reach almost to the earth; for its semidiameter contains 43°, and if it contained 45° it would pass through the centre of the earth. The reply is to deny the antecedent. The semidiameter of Venus's epicycle does not contain 43 degrees of the heaven of Venus, as Fracastoro falsely assumes, but 43 parts of such a kind that 60 of them are contained in the semidiameter of its eccentric. Further, if you consult the least Ptolemaic and Alphonsine distance of Venus from the earth, which we set out in Book 7, Section 3, chapter 1, and Section 6, chapter 2, you will see that it is 179 2′ semidiameters of the Earth according to Fernelius [Jean Fernel], but 167 57′ according to Maurolico and Clavius. But in our hypothesis, which we think truer, the least distance of Venus is at least 1917 terrestrial semidiameters.

[Margin: 9. Objection, of Averroes and Fracastoro.]

Ninth: if the Moon were rolled round on an epicycle, we would not always see the same face of the Moon, but one face at the apogee of the epicycle and another at the perigee. But we always see the same one. Therefore … I reply: if no other motion were attributed to the Moon, I grant the major premise. But I deny it if there is attributed to the Moon either a turning about its own centre, in the direction contrary to the motion of the epicycle, as Fernelius attributes in his *Cosmotheoria*; or if you transform the epicycle into a second eccentric, as Maginus does; or if you use other equivalent hypotheses, on which enough was said in Book 4, from chapter 26.

The remaining objections rest either on false observations or on the mere authority of Aristotle defending concentrics. Yet just as Aristotle subscribed in this to Eudoxus and Callippus, he would certainly have accepted other hypotheses had he lived after Ptolemy and learned astronomy from him; for he himself professed that in these matters the more skilled astronomers are to be consulted. In book 2 *On the Heavens*, chapter 7, text 34, he says: *When, therefore, someone has attained more certain necessities, then thanks must be given to those who discover them; but for now what seems so must be said.* And in *Metaphysics* 12, text 45, on the lations of the planets, he says: *As to how many these are, we for now state what some of the mathematicians assert, for the sake of understanding, so that we may grasp in the mind some determinate plurality. Further, some things we ought*

to seek out ourselves, and others to inquire of those who investigate these matters, if anything beyond what has so far been handed down seems to be so to those who deal with these things; and to love both, but to adhere to the more certain.

[Margin: The modesty of Aristotle's mind.]

And a little later he admits that he has spoken of these things only probably, and that necessary demonstrations are to be sought from those more skilled in these matters, when he says: *Therefore it is reasonable* — in Greek λογικῶς [Greek: logikōs, "reasonably"], that is, topically and with likelihood — *to judge that the substances and principles, both the immobile and the sensible, are so many; for what is necessary may be left to the more powerful to say.* Let those Peripatetics hear this, who contend that Aristotle, even against his will, always pronounces infallible oracles; and who, instead of letting him walk in the Peripatos ready to follow better things, try to carve him for posterity as a stone statue, fixed immovably to opinions once conceived.

CAPVT III.

Chapter 3.

An detur Motus Primi Mobilis diſtinctus à motu Fixarum ac Planetarum, & in quo ſubiecto, & An illi contrarius ſit motus ſecundorum Mobilium, Quaq. ratione hi duo motus ſimul Conciliari poſſint.

Whether there is a Motion of the Primum Mobile distinct from the motion of the Fixed Stars and of the Planets, and in what subject; and whether the motion of the Secondary Mobiles is contrary to it; and in what way these two motions can be reconciled with each other.

I. No motion among the celestial motions is better known than the motion of the primum mobile, by which, namely, we see all the stars, and especially the fixed stars, carried round every day in 24^{h} from one and the same point of the heaven back to the same point, towards the west. And yet nothing is more obscure, whether as to the subject of this motion, or as to its distinction from the other motions of the stars, and the way of combining them with one another without any physical incompatibility. I touched on this controversy in Book 6, chapter 18, in setting out the Theorica of the eighth sphere and of the fixed stars. But since I have afterwards come upon other authors, and repeated contemplation of this motion has yielded some new reasons not unworthy to be known; and since this, after all, is its proper place, where we treat of what is universal and common to all the stars, I am glad to bring it back to the anvil.

[Margin: The first opinion, placing the primum mobile in the single motion of the fixed stars.]

II. The first and most ancient opinion was that the fixed stars are moved by no motion other than the diurnal and common one towards the west. Their own peculiar motion upon the poles of the zodiac, with a change of declination, had not yet been detected by certain observation, since it is perceptible only

after many years and cannot be evidently demonstrated within the ordinary span of one observer's life. On this supposition the first motion was nothing other than the motion of the fixed stars themselves, or of the eighth sphere, about the axis of the Equator and upon its poles; the eighth sphere itself was the Primum Mobile and the highest astronomical heaven; and the universal visible time, and the best-known measure, was nothing other than the revolution of any single fixed star — the Dog Star, say — to the same point of the same fixed meridian.

[Margin: The authors of this opinion: the Babylonians, the Egyptians, Eudoxus, Callippus, Aristotle.]

That the Babylonians, and some of the Egyptians and Greeks, but especially Eudoxus and Callippus, and Aristotle too, held this opinion is gathered from Aristotle himself, *On the Heavens* book 2, from chapter 9, that is, from text 57 to 70, and *Metaphysics* 12, from text 42 to 51. There, together with Eudoxus and Callippus, he attributes a single and most simple lation to the sphere of the non-wandering stars; and among the other causes for which it is filled with innumerable stars, he adduces this one: that the simplicity of its motion is compensated by the multitude of its stars, and that, just as the spheres of the wandering stars have a single star but several motions, so the sphere of the non-wandering stars has a single motion but several stars. So he says in *On the Heavens* 2, text 67. And he reports, in *On the Heavens* 2, text 60, that this account of astronomy flowed from the Egyptians and Babylonians to the Greeks. For this reason the most ancient Babylonians and the Egyptians, as Albategnius reports (chapter 27 of *De scientia stellarum*), defining the year, said that it was *the revolution of the Sun to the same fixed star* — just as if the fixed stars were fixed points, movable by no motion other than the diurnal. And Nembroth the Chaldean, in his astronomical work as cited by Augustinus Riccius [Agostino Ricci] in his treatise *De motu octavae sphaerae*, ascribes only a single motion to the signs of the heaven. Nor were Hesiod and the other most ancient poets of the Greeks of a different opinion when they placed the nine Muses in the heaven: for to the highest, namely Calliope, they ascribed no peculiar voice and no motion, as Glareanus [Heinrich Glarean] notes (*Dodecachordon* book 2, chapters 8 and 13), but the highest and shrillest voice, on account of its very great speed of motion — the voice which for Glareanus himself is Μέση [Greek: Mesē, a note-name, "the middle"] — they gave to Urania, who governs the sphere of the fixed stars. Calliope, therefore, as mistress of the celestial harmony, presided over the other Muses and over keeping the motions of all eight heavens together in concord, and contained the voices of all, as Macrobius expressly teaches from Hesiod (book 2 on the *Dream of Scipio*).

There are some who doubt what Plato's view was. But in book 10 of the *Republic* he brings in a certain Pamphilius, killed in battle and returning to life from the underworld, who asserts that *he saw the tracks of eight celestial motions, of which the eighth was driven in the swiftest course*; and in the *Epinomis* he says: *The philosopher ought not to be ignorant of how the seven circuits turn beneath the*

first. Nor, surely, would his pupil Aristotle have kept silent about it if Plato had taught some motion in the fixed stars other than the diurnal; nor would *Cicero*, who in the *Dream of Scipio* carries a great deal over into Latium from Plato's books on the *Republic*. For there he mentions nine globes, of which he assigns the lowest to the immobile earth and the highest, the heaven of the fixed stars, with a single motion. He says:

[Margin: Cicero's opinion.]

All things are bound together for you in nine orbs, or rather globes, of which one is the celestial, the outermost, which embraces all the rest, itself the supreme God, enclosing and containing the others; in it are fixed those everlasting courses of the stars which revolve. Beneath it are seven, which turn backwards with a motion contrary to the heaven. And after listing the seven globes of the planets he adds: *for the one that is in the middle and ninth, the earth, does not move, and is the lowest*; and a little later: *but those eight courses, of which two have the same force, produce seven sounds distinguished by intervals*; and indeed a little before he had said: *and nature brings it about that the extremes sound low at one end and high at the other. For this reason that highest course of the star-bearing heaven, whose revolution is swifter, moves with a high and rapid sound, but this lunar and lowest one with the deepest.*

[Margin: Macrobius's opinion of Cicero's opinion.]

Granted, Macrobius (book 1 on the *Dream of Scipio*, chapter 17) thought that the proper motion of the fixed stars was known to Cicero and indicated by him. For he says: *Apart from the two Lights and the five stars which are called wandering, some have said that all the others are fixed in the heaven and are moved only with the heaven; others (whose assertion is nearer the truth) have said that these too advance by their own motion, because [?] they are carried along with the revolution of the heaven; but that, because of the immensity of the outermost globe, they spend ages exceeding any credible number on a single circuit of their course, and that therefore no motion of theirs is perceived by man, since the span of human life is not enough to detect even a brief point of so slow an advance.* Hence Tully, ignorant of no school approved by the ancients, touched on both opinions at once when he said *in which are fixed those everlasting courses of the stars which revolve*: for he both called them fixed and did not leave unsaid that they have courses. But who would not see that Cicero is being dragged here by force? From the whole context of those words it is plain that he understood no course in the fixed stars other than the course of the highest heaven, by whose running they run.

[Margin: Philo's opinion.]

Philo too, a Platonist to be sure, says in his book *On the Cherubim*: *The heavenly orbs have motions contrary to each other; one of them carries the fixed stars to the right, the other the wandering stars to the left. But that outermost orb of the fixed stars is one, which is turned from east to west; while the inner seven, namely those of the wandering stars, whose course is at once compelled and voluntary, have two motions contrary to each other: the compelled one being like that of the fixed stars, etc.*

[Margin: The opinion of St Ambrose and St Damascene.]

St *Ambrose* also expressed this opinion (*Hexaemeron* book 2, chapter 2), whose words we shall report in Section 3, chapter 1, number 9; and so did Damascene, when in book 2 of *On the Orthodox Faith* he granted motion towards the east to the seven planets alone, saying: *For they assert that there are seven planets, the Sun, the Moon, Jupiter, etc. They have called these planets, that is, wanderers, because they perform their motion contrary to the heaven: for the heaven and the other stars are moved from east to west, but they alone have their motion from west to east.* Some scholastics seem to have held this opinion, especially *St Bonaventure* (on book 2, distinction 14, article 1, question 1) and *Aegidius* [Giles of Rome] (*Hexaemeron*, part 2, chapter 36), in these words: *Therefore the orbs of the planets, because they abound in motions, are lacking in stars; but the eighth sphere, because it abounds in stars, is lacking (so to speak) in motions, since it has only one motion. Ruuius* too (*On the Heavens* 2, chapter 5, question 1) and *Hurtadus* (disputation 1 on the heavens, section 1) have called the proper motion of the fixed stars into doubt.

There is also extant a little book by *Aben-Ezra* entitled *Misphate hamazaloth*, that is, *On the Judgements of the Stars*, where it is said: *The great and glorious orb, where the glorious hosts of God are, is called the heaven of heavens, because beneath it are the orbs of the seven planets.* So this author does not seem to recognise any heaven above the seven planets other than the single heaven of the fixed stars — which, however, he wrongly confuses with the Empyrean. Nor did *Pliny the Elder* (book 2, chapter 8) recognise any motion of the fixed stars other than this one, nor *Vitruvius* (book 9, chapter 4).

As for the contention of *Iosephus Scaliger* [Joseph Justus Scaliger], in book 4 of *De emendatione temporum*, page 283, and in the *Diatriba de aequinoctiis*, chapter 1, that Thales of Miletus, Meton, Euctemon, Aristyllus or Aristarchus, and Timocharis came, from the difference between the tropical year of the Sun and the sidereal year of the fixed stars, to suspect some proper motion of the fixed stars by which they gradually receded from the equinoctial points in the order of the signs — that is a suspicion of Scaliger's rather than a proven assertion. For *Ptolemy* (*Great Syntaxis* book 3, chapter 2, and book 7, chapters 2 and 3) attributes that first conjecture and recognition of the proper motion of the fixed stars — made, it is true, from places of the stars observed by Aristyllus and Timocharis — to Hipparchus, who compared his own observations with theirs; and Ptolemy himself afterwards made it more certain by collating his own observations with those of Hipparchus.

[Margin: 2. The opinion that distinguishes two motions really, and heavens for them.]

III. The *second* opinion was that of those who, following the lead of Hipparchus and Ptolemy, recognised two apparent motions in the fixed stars: one upon the poles of the Equator, from east to west, very swift, and completing its revolution in the space of 24 hours; the other upon the poles of the ecliptic, from west to east, very slow. They recognised them in such a way that they held it necessary, for the diurnal motion, to have a heaven really distinct from the heaven of the fixed stars, that is, from the eighth sphere — a heaven by

which all the lower spheres would be swept to the west; and they accordingly called this motion the motion of *Raptus*, of sweeping along.

[Margin: 1. Class of the 2nd opinion, positing 9 mobile spheres.]

Within this opinion, however, three classes of authors must be further distinguished. The authors of the *first* class posited only nine celestial spheres, and so recognised the ninth as the primum mobile: Rabbi Moyses; Rabbi Iosue in the *Book of Demonstrations*; Haly on the *Quadripartitum*, chapter 11; and many Jews — indeed *Abenezra* himself too, in the book *Taamin*, that is, *Of Reasons*, as Augustinus Riccius reports (*De motu octavae sphaerae*, chapter 4). *Sacrobuschius* [Johannes de Sacrobosco] on chapter 1 of the *Sphere*; *Scotus* on book 2, distinction 14, question 2, and on *Metaphysics* 12, comment 44; *Caietanus* on 2 Corinthians 2; *Delphinus*, *De caelestibus globis*, chapter 30. Finally *Mastrius and Bellutus* [Bartolomeo Mastri and Bonaventura Belluto] (disputation 2 on the heavens, question 1, article 2) distinguish the primum mobile from the starry heaven, but posit a single starry heaven. Of these, Caietanus and Delphinus say that the primum mobile is the crystalline heaven.

[Margin: 2. Class: 10 spheres.]

The *second* class posits 10 mobile spheres: namely, the tenth for the primum mobile; the ninth for imparting the motion from west to east to the fixed stars and to the auges of the planets, the Moon excepted; and the eighth for the motion of access and recess from the equinoctial points, that is, the libration or trepidation in longitude. In this class were many Arabs, Moors and Jews, but especially *Alphonsus*, King of Spain [Alfonso X]; *Georgius Purbachius* with his followers; *Io. Regiomontanus* in the *Theorica* of the eighth sphere and in book 7 of the *Epitome of the Almagest*, proposition 6; *Petrus Apianus* [Peter Apian] in the *Opus Caesareum*; *Io. Baptista Amicus* [Giovanni Battista Amico], *De motibus caelestibus*; and *Petrus Alliacensis* [Pierre d'Ailly], question 2 on the *Sphere*, who reports the opinion of 10 mobile spheres and does not refute it; *Maurolico*, dialogues 1 and 3 of the *Cosmographia*, pages 24 and 89; *Fernelius*, *Cosmotheoria* book 2, chapters 1 and 7; *Iosephus Langius* in the *Elementa astronomica*, chapter 4; *Clavius* in the earlier editions of the *Sphere*, pages 44 and 72; the *Conimbricenses* [the Coimbra commentators] on book 2 *On the Heavens*, chapter 5, question 1. To this class can be referred Tebith, Arzachel [al-Zarqālī] and Isaach Israelita [Isaac Israeli of Toledo], in the second treatise of *De fundamento mundi*, inasmuch as they admitted a motion of trepidation of the fixed stars in longitude — granted that they ascribed its cause to the ninth heaven rather than to the eighth, or left this arrangement of the orbs in doubt.

[Margin: 3. Class: 11 spheres.]

The *third* class posits eleven mobile spheres: the eleventh for the primum mobile; the tenth for the trepidation or libration in latitude, to be imparted to all the lower spheres so that they follow the variation of the obliquity of the ecliptic; the ninth for the trepidation or libration in latitude, by force of which the anomaly of the motion of the fixed stars and of the precession of the equinoxes is produced; and finally the eighth for the equal or mean motion of

the fixed stars towards the east. So, namely, *Ioannes Vernerus* [Johannes Werner], as cited by Erasmus Osualdus [Erasmus Oswald Schreckenfuchs] on Peuerbach's *Theorica* of the eighth sphere; *Io. Antonius Maginus* in the *Theoricae*, book 1, and in the Secondary Mobiles, canon 18; *Leupoldus de Austria* [Leopold of Austria] in his *Compilatio*; *Clavius* in the last edition of the *Sphere*, page 36 — which is why Scheinerus [Christoph Scheiner], in the *Disquisitiones mathematicae*, number 22, calls it the Clavian system. The same number of mobile spheres, according to the old opinion, was set out by *Antonius Deusingius* [Anton Deusing] and *Petrus Gassendus* [Pierre Gassendi] in their *Institutiones astronomicae*. Some of the authors of the second class, however, especially Clavius and the Conimbricenses, admit an eleventh, immobile heaven, that is, the Empyrean. Indeed Clavius thinks that the aggregate of the 9th and 10th heavens is the glacial and crystalline heaven, which has earned the name of *the waters above the heavens* in the sacred writings, because of its transparency and because in it no parts are denser than others.

[Margin: 3. The opinion of Turrianus and Fracastoro, on 14 mobile heavens.]

IV. The *third* opinion was that of *Io. Bapt. Turrianus* [Giovanni Battista della Torre] and *Girolamo Fracastoro*, in the *Homocentrica*, section 2, from chapter 11 to 17. There he posits above the Aplanes, that is, the sphere of the non-wandering stars, other mobile orbs really distinct from it, but differing in number, order and function from those that the authors of the second opinion posited; and he gives different hypotheses for these motions, according as one may wish to recognise a motion of trepidation and of the fixed stars both direct and retrograde, or only direct. But since he himself in the end thinks it more probable that the motion of the fixed stars is always retrograde, though unequal, he concludes in chapter 17 that above the Aplanes there are 14 orbs.

The first or highest is the *Primum Mobile*, which with marvellous speed, in 24 hours, sweeps with it from east through west back to the same east all the orbs enclosed within it. The second is the *Circumducens* [the Leader-round], which cuts the Equator of the primum mobile at right angles; carried round in latitude through the upper colure from north to south in 3600 years, it carries all the lower orbs with it, except in so far as some counter-carried orbs hinder it. The third is the *Circitor* [the Circuiter], which proceeds through the lower colure, that of the equinoxes; it is moved accidentally by the *Circumducens*, in 3600 years, from south to north, but of itself it is moved towards the opposite quarter. The fourth orb is the one *Contravectus* [Counter-carried] *both to the Circitor and to the Circumducens*, and it is borne through the upper colure from south to north with twice as swift a motion, that is, in 1800 years. The fifth is the *Anticircitor*, which is carried round by the Contravectus always towards the part opposite to the Circitor. The sixth is the *Contravectus to the Anticircitor*, yielding to it insensibly, so that the Aplanes is not carried round with a sensible motion in latitude. And beneath it, finally, is the *Aplanes*, the orb bright with so many lights and marked out by the Milky circle, which of itself completes one degree in 100 years and fulfils its revolution in 36000 years, but within

that revolution is now slower, now faster. Thus above the eighth sphere these authors posit six mobile orbs, so that there are 14 in all.

[Margin: 4. The opinion of a primum mobile that is distinct but does not sweep along.]

V. The *fourth* opinion does admit a ninth heaven really separate from the eighth sphere, to be the primum mobile; but it denies that the lower orbs are swept along by it — that is, physically drawn or carried — and it does not grant absolutely that the participation in the first motion is compounded of two motions really distinct and contrary. But it does not explain in one and the same way how the sphere of the fixed stars and the spheres of the seven planets are moved by that primum mobile.

[Margin: 1. Class of this opinion.]

For *Alpetragius*, in his *Theorica physica* of the celestial motions, and more or less Achillinus in his book *De orbibus*, deny that the primum mobile sweeps the lower orbs along by identity, continuity or immediate contact. He says rather that the first Mover, or first Intelligence, impresses on the separate orbs a revolving motion from east to west, just as an impetus is impressed by someone throwing a stone or shooting an arrow; and that this impetus grows weaker and weaker the farther the spheres of the secondary mobiles are from the primum mobile. Accordingly all of them, of themselves, are carried round from east to west by a motion that is simple as regards longitude, but they do not reach the speed of the primum mobile by their own motion; and therefore the fixed stars and the planets appear accidentally to recede towards the east and to strive against the primum mobile, whereas in reality this motion is a single one, towards the west — slower, however, in the fixed stars, slower still in Saturn, and slowest in the Moon. But because he knew that this motion is oblique, and runs along helices, that is, a gyrating line, which the Arabs call *Lacalabinum*, and that the fixed stars change their declinations, he said that this motion takes place upon various poles that go round the poles of the world by force of little circles. And because, following Hermes, Theon and Arzachel, he suspected that the motion of the fixed stars is sometimes retrograde, or at least unequal, he posited an unequal motion of the poles of the eighth sphere in circles about the poles of the world. In a proportional way he explains the anomalies of the planets, their directions, stations and retrogradations, without epicycles and eccentrics.

Against him rise Augustinus Riccius (*De motu octavae sphaerae*, chapter 10), Fracastoro (*Homocentrica*, section 2, chapter 3), *Clavius* (on the *Sphere*, page 48) and other more recent astronomers. But while Alpetragius is rightly criticised in that by this hypothesis he neither explains nor maintains the motion of the planets in altitude — thinking, I believe, that it is apparent and not true — he is unjustly criticised in that he maintains the oblique motion of the fixed stars, or the anomalies of the planets in longitude and latitude, as though he had explained that motion upon the same poles and along the same line.

[Margin: 2. Class of this opinion.]

Another form of this opinion is that of Petrus Alliacensis, Cardinal and Bishop of Cambrai. In questions 2 and 9 on the *Sphere* he posits a tenth, immobile orb, to keep the different properties of the terrestrial regions unchanging through its influences; and he posits the ninth heaven as the primum mobile, in question 4. But he too denies that the lower orbs are swept along or drawn by it, or swept along properly and physically by the primum mobile. For he says that the individual orbs have their own Intelligences, and that from the primum mobile, or mover, a certain power flows into the lower ones which inclines them to a motion similar to the motion of the primum mobile — just as nature inclines heavy things to motion upwards, so that a vacuum may be avoided — and that such a motion is therefore neither purely natural nor violent, but would be violent and impossible if they were swept along by the primum mobile. He grants, moreover, that this motion takes place upon different poles and axes, and in question 13 he admits epicycles and eccentrics, or a motion equivalent to them, on account of the elevation and depression of the planets. Hence on this opinion the fixed stars and the planets are really moved with a single motion towards the west, and strive to imitate the primum mobile; but because they do not imitate it perfectly, they seem, by their slowness, to travel back towards the east.

[Margin: 5. The opinion positing the primum mobile as the ninth heaven, but crystalline, and without sweeping along.]

VI. The *fifth* opinion is that of *Ioannes Antonius Delphinus*, of the Franciscan family. In his book *De globis ac motibus caelestibus*, chapters 19, 29 and 30, he affirms with Alpetragius that there is a primum mobile and that it is the ninth heaven, but that this is the crystalline or watery heaven, which sacred Scripture calls by the name of *the waters above the heavens*; and that all the orbs are concentric with the world. He says, however, that each is moved by its own Intelligence, that is, by Angels, always from east to west, yet so that they move more slowly than the first Intelligence moves the ninth heaven, and moreover now towards the south, now towards the north; and this not by natural necessity but by free will, because they willingly serve the Creator who commands such a motion. Lastly, he calls the name "ninth mobile" metaphorical, inasmuch as that heaven does not move the lower spheres or globes physically, but only as the first exemplar of the swiftest motion towards the west; and he says that the apparent motion towards the east comes from their being left behind by the swifter motion of the primum mobile. To this opinion can be referred *Chiaramonti* (*De universo*, book 2, chapter 18, and book 6, chapter 1), inasmuch as he posits as the primum mobile a ninth heaven which the other spheres, moved by the Intelligences with the diurnal motion alone, do not keep pace with, and which they therefore appear to fall behind towards the east.

[Margin: 6. The opinion denying a primum mobile distinct from the 8 spheres, but positing two motions.]

VII. The *sixth* opinion denies that there is a primum mobile really distinct, by an adequate distinction, from the eighth sphere and the remaining seven; it

says that it is distinguished only as a whole is from its parts taken one by one. It admits, however, two motions. For the whole world, except the globe of the earth, is moved from east to west — that is, the eighth sphere, the seven orbs of the planets, and the element of fire and of air. And the primum mobile, under one aspect, is the aggregate of all eight spheres, which by priority of nature is moved in this way before its parts are; under another aspect it is the eighth sphere, inasmuch as the Intelligence moves it principally, as the nobler heaven — just as the soul is said to move first and principally the heart, and then the other members. Yet just as the heart does not move the other members, so neither does the sphere of the fixed stars sweep the other spheres along; it is moved together with the whole by the same Intelligence, just as the whole body is moved by the same soul. And it holds that there is in each heaven a twofold appetite, one for the motion of the whole towards the west, the other for the motion proper to it, towards the east; and that these motions do not conflict with each other, just as a particular motion of the hand, sometimes towards the opposite side, does not conflict with the motion of the whole animal body towards one side. So holds *Augustinus Riccius* in the treatise *De motu octavae sphaerae*, chapters 1, 13, 14, etc.; and so *Orontius Finaeus* [Oronce Finé], *Sphere* book 1, chapter 5, saying: *The primum mobile, then, is to be called the world itself, and not some particular celestial orb. The second difference of motion, however, belongs to the particular orbs themselves, which are parts of the whole heaven; for each of the particular orbs strives against it with its own motion from west through south towards east, etc.* Riccius, however, denies (chapter 22) that there is one celestial body moved by a single lation, although in the same place he grants to the theologians that there is one immobile body, namely the Empyrean.

To this class can be referred those unnamed authors who, as reported by *Fracastoro* (*Homocentrica*, section 2, chapter 10), said either that there is a single Intelligence in all eight spheres, moving them westward, and another Intelligence in each of the seven orbs, so that there would be eight in all; or that there are two in each orb — say two in the eighth and two in the seventh — so that there would be sixteen, of which one would move its orb westward and the other eastward, obliquely. *Oviedus* too points to this opinion about one or two Intelligences (the single controversy on the heavens, point 4). *Clavius*, moreover, refutes the opinion of Riccius and Orontius (on the *Sphere*, page 49) as impossible: for just as it is impossible, he says, for a whole animal to advance westward at the same time as each of its parts, without exception, goes back eastward, so it is impossible for each of the eight heavens to be carried eastward at the same time as the whole aggregate of them is rolled round to the west. Fracastoro, for his part, says that it follows that the Intelligences never move according to their nature, since one always resists the other and hinders it from moving its heaven with as much speed as it otherwise would; and this he thinks violent and unfitting for powers and Intelligences so excellent.

[Margin: 7. The opinion denying two motions, and a primum mobile above the 8th sphere.]

VIII. The *seventh* opinion is similar to the opinion of Alpetragius set out in number 5, but differs from it in that it denies that there is above the eighth sphere another heaven which is the primum mobile. For it says that the primum mobile is the eighth sphere, inasmuch as it revolves the fastest of all towards the west, and in the space of 24 hours restores the same stars to the same point of the same meridian or horizon from which that motion began on the first day of the world; but that this sphere does not sweep along the other, lower spheres, as certain authors of the first opinion, explained in number 2, held. For it says that the remaining lower spheres, moved either by their own power or by an Intelligence, are of themselves carried towards the west and aim at the same kind of motion that the eighth sphere performs, but cannot attain its speed; and that each day they reach the same point of the same meridian or horizon somewhat more slowly than it does, and the more slowly the farther each is from the eighth sphere. The result is that, because the slower planets are left behind each day by the faster fixed stars and are separated from them more and more, the planets appear to go back towards the east — granted that in reality they do not go back, and are not moved with a twofold motion but with a single one towards the west, though a slower one; and it is called a motion towards the east not absolutely or truly, but comparatively, with respect to the faster one, and in appearance.

[Margin: Anaxagoras, Democritus, Cleanthes.]

Plutarch (*De placitis* book 2, chapter 16) indicates fairly ancient authors of this opinion, though he adds the contrary opinion, when he says: *Anaxagoras, Democritus and Cleanthes think that all the stars are carried from east to west; Alcmaeon and the mathematicians, that the wandering stars are rolled with a motion contrary to the non-wandering stars, namely from west to east.*

[Margin: Ptolemy's criticism of this opinion.]

And at the same time — though somewhat younger than Plutarch — *Ptolemy* (*Almagest* book 1, chapter 8) indicates that the same view could stand if the apparent motion of the planets always took place in circles parallel to the Equator, without change of declination; but that, since it happens otherwise, it cannot. For he says: *Thus, if the progress of the wandering stars took place in circles equidistant from the Equinoctial, that is, about those poles about which the first revolution takes place, one might quite rightly suppose that the revolution of all is one and the same, following the first. For it would seem credible that their progress comes about not through an opposite motion, but because they are left behind by the first. But as it is, together with their progress towards the east, they also approach the north or the south, and not even an equal quantity of this approach is seen, so that this accident seems to come about through certain impulses in them, etc.* From this he concludes that two distinct great circles are necessary: namely the Equator, for the primum mobile carrying the fixed stars and the planets round to the west, and the Zodiac, within which the planets proceed obliquely to the east. So, since in book 7, chapters 2 and 3, he recognised that the fixed stars too advance slowly eastward upon the poles of the ecliptic, he seemed to some to suppose a

ninth heaven as the primum mobile, and to others both motions in the eighth heaven. But this about Ptolemy in passing.

Martianus Capella attributes the same opinion to the Peripatetics (*De nuptiis Philologiae* book 8, in the chapter on the orbs of the planets), saying: *Finally, the doctrine of the Peripatetics also contends that these stars are not moved forward against the world, but are passed by the speed of the world, which they could not follow.*

[Margin: Fracastoro's criticism of the same.]

Fracastoro, moreover, mentions this seventh opinion without naming anyone (*Homocentrica*, section 2, chapter 3), and refutes it on these grounds: if all the orbs are carried of themselves westward in longitude, they would be moved in latitude accidentally, and so by the force of some higher orb or Intelligence. This, he says, is unfitting, because it would follow that the planets are deflected by that orb which moves them sideways in such a way that on one and the same day the Sun, rising at the northern summer rising on this side of the Equator, would set beyond the Equator at the southern winter setting — which is contrary to observations. But that inference is not necessary. For they can be carried of themselves, by the same motive force, at once westward and obliquely, along spirals or helices, gradually deflecting from the parallels to the Equator, so that they appear to rise and set on nearly the same parallel, with a difference that is the smaller, the smaller the sideways bending by which they vary their declination from the Equinoctial and their latitude from the ecliptic. Therefore neither Fracastoro's refutation, nor Ptolemy's, nor that of Clavius — who attacks this opinion, which is in part that of Alpetragius and Achillinus, on page 49 of his *Sphere* — is solid as regards the oblique motion of the planets. There remains, however, a difficulty arising from the proper and oblique motion of the fixed stars which appears to us: for if they too appear to advance towards the east because they move rather slowly, then their motion is not the first motion, and it seems that another, swifter motion towards the west must be assigned, in comparison with which the fixed stars would be slower. We shall come back to this matter below.

[Margin: 8. The opinion of Iosephus Scaliger, denying the motion of the eighth sphere.]

IX. The *eighth* opinion was that of Iosephus Scaliger, in his *Diatriba de aequinoctiorum anticipatione* and in book 4 of *De emendatione temporum*, from page 284. He says that the motion of the eighth sphere eastward upon the poles of the ecliptic is a kind of monster, an old wives' and trifling tale. For the fixed stars, he says, are neither moved with a motion in longitude, or εἴς τὰ ἑπόμενα [?] [Greek: eis ta hepomena, "towards the following (signs)"] — that is, not in the order of the signs — nor do they change their declinations or distances from the poles of the world, which he posits as immobile; but the equinoctial and solstitial points are moved εἴς τὰ προηγούμενα [Greek: eis ta proēgoumena, "towards the preceding (signs)"], that is, against the order of the signs, towards the west. It is not the stars that recede from the Sun, but the Sun that recedes from the stars and keeps the equinoxes and solstices each year at

points of the Equator farther and farther to the west; and this is why the fixed stars appeared to Hipparchus and Ptolemy to move eastward, and why they persuaded a credulous posterity of it. Next he says that the poles of the Equator are distant from the poles of the world, and move westward along small circles described about the poles of the world; and that from this motion it comes about that the stars appear to change their declinations and their distances from the poles of the world. Further, that from this it comes about that all meridians are mobile, and that the equinoctial circle is not perpetually at right angles to the poles of the world, so that the position of meridian lines gradually varies, and sundials laid out on them become deceptive after some years. He professes to have observed outstanding evidence of this in the monuments of antiquity, and he thinks that the changes of the magnetic declinations can be referred to this. Thus by this fiction Scaliger frees himself from the trouble of reconciling two motions in the eighth sphere, since he grants it the single motion of the primum mobile and attributes the other to the equinoctial points, against the order of the signs.

The foundation of this opinion is that the pole star, which shines in the tail of Ursa Minor, was seen to be equally distant from the pole of the world — that is, 12° 24′ — both in the time of Eudoxus, namely Olympiad 103, or the year 367 before Christ, and in that of Eratosthenes, or the year 227 before Christ, and in the time of Marinus of Tyre and Ptolemy, who in the year

130 after Christ flourished. So from Eudoxus to Ptolemy there are about 500 years, in which that star certainly ought to have changed its distance from the pole of the world. In the same way, says Scaliger, the southernmost star of the same Bear stood equally distant from the pole of the world at both times, that of Eudoxus and that of Ptolemy, and stands so even now. In his letter to Dauid Riualtus [David Rivault de Flurance], too, which is at the end of the *Diatriba*, he relates the risings and settings of the stars that he collected from Hipparchus of Bithynia, and says that they cannot be understood unless a globe is constructed whose pole is distant from the tail of Cynosura by 12° 24′. When he communicated this to Tycho Brahe, Tycho, he says, was astonished at the novelty and strangeness of the ἐπιχειρήματος [Greek: epicheirēmatos, "of the undertaking"] — and rightly so. Copernicus, moreover, he says, in large part favours him, since Copernicus said that the equinoxes move forward [in anteriora procedere], and not that the eighth sphere moves in the order of the signs. In the end Scaliger admits that much concerning the construction of the sphere is still hidden from us, and he implores the help of more learned mathematicians to weigh and discuss these things more accurately. They did so indeed; but no one has been found willing to rear this offspring of his. Rather, as a monster born for the ruin of astronomy, it was smothered at once by four most learned men of our Society: above all the most erudite *Dionysius Petavius* [Denis Pétau], in his books *De ratione temporum* and in the dissertations of the *Uranologion*, book 3; and also *Paulus Guldinus* [Paul Guldin], book 2, chapters 9 and 10, *Against Calvisius*, the enemy of the Gregorian calendar; *Georgius*

Furnerius [Georges Fournier], book 10 of the *Hydrographia*, chapter 26; and *Clavius* on the *Sphere*, page 62. Outside our Society, *Ismaël Boulliau*, book 5 of the *Astronomia Philolaica*, chapter 4. We, for our part, have sufficiently overturned his foundation concerning the distance of the pole star from the pole of the world, partly in book 3, chapter 28, number 10, and partly in book 6, chapter 4, where we treat of Ursa Minor and of the pole star's approach to the pole of the world. I now add this: although at first sight it may seem that the motion of the fixed stars in longitude can be attributed to the equinoctial points advancing westward, yet, since according to Scaliger their advance comes about[27] only through the Sun, which keeps the equinoxes at points ever farther west — while the Sun is seen each day to become not more westerly than the fixed stars but more easterly — it is too difficult, and almost impossible, to defend this very thing.

[Margin: 9. The opinion attributing the primum mobile and all motion of the fixed stars to the Earth.]

X. The *ninth* opinion denies to the fixed stars all motion, both the diurnal one westward and the proper one eastward. To the planets it grants a proper motion eastward, but denies to them too the diurnal one westward. For the diurnal motion which appears in the fixed stars and in the planets, it says, is in reality the motion of the Earth about its own centre and axis, by which, in a rotation of 24 hours, it is spun round towards the east; and so it is we who go to meet the stars towards the east, and we who rise to them rather than they to us. The proper motion of the fixed stars, on the other hand, it attributes to the equinoctial points on the terrestrial equator, which precede westward by the force of a certain libration about the Earth's axis, indicated in book 3, chapter 29.

[Margin: 1st class, attributing an annual motion to the Earth.]

But the authors of this opinion split into two classes. The first attributes the annual motion, which produces for us the alternation of the four seasons, not to the Sun but to the Earth: the Earth not only turns daily about its own centre, but is also carried annually, together with its centre, under the ecliptic eastward around the Sun, which rests in the middle of the world, or at any rate is not carried from its place.

[Margin: Philolaus.] [Margin: Aristarchus.] [Margin: Copernicus and his followers.]

So held Philolaus long ago, according to *Plutarch* (*De placitis philosophorum* book 3, chapter 13), and after him Aristarchus of Samos, as *Archimedes* relates in the *Arenarius* [*Sand-Reckoner*]. This opinion was revived by *Nicolaus Copernicus*, not as a hypothesis, as some excuse him, but absolutely, as is clear from the preface to Paul III prefixed to the books of the *Revolutions*, and from book 1, chapters 8, 10 and 11, and book 5, chapter 2. It was embraced by Mästlin, Rheticus, Caelius Calcagninus [Celio Calcagnini], Rothmannus [Christoph

[27]the print reads "f t", one sort not printed

Rothmann], Galileo, Didacus Astunica [Diego de Zúñiga], Paulus Anton. Foscarinus [Paolo Antonio Foscarini], Antonius Laurentinus Politianus, but most zealously of all by *Johannes Kepler*, in his *Mars*, in the *Epitome of Copernican Astronomy*, in the *Mysterium Cosmographicum*, and in the *Harmonice*.

[Margin: 2nd class, denying an annual motion to the Earth.]

The *second* class, however, grants its own proper motion to the Sun as well as to the other planets — to the Sun, indeed, the annual one — but leaves to the Earth the diurnal motion, a rotation of 24 hours about its own immobile centre, and does not carry the Earth from one place to another.

[Margin: Heraclides, Ecphantus.]

So held, long ago, Ecphantus and Heraclides, according to Plutarch (*De placitis* book 3, chapter 13), and Nicetas of Syracuse, according to *Cicero* (*Academica* book 2 and *Tusculan Disputations* book 1). They were followed later by *Longomontanus*, in his *Astronomia Danica*, book 1 of the *Theorica*, chapters 2 and 4; by *William Gilbert* [Gulielmus Gilbertus], book 6 of the *Philosophia Magnetica*, chapter 3; by *Origanus*, tome 1 of the *Ephemerides*, in the dedicatory epistle; and by *Andrea Argoli* in the *Pandosion sphaericum*, chapter 3. The same opinion is ascribed to Plato in the *Timaeus* by *Aristotle* (*De caelo* book 2, text 75), *Cicero* (*Academica* book 2) and *Laertius* in his life of Plato. But we shall make it plain from Plato's *Timaeus* itself, in section 4, chapter 2, number 2, that Plato stood for the immobility of the Earth.

[Margin: 10. The opinion leaving [?] a proper motion to the fixed stars [?], but attributing the diurnal motion to the Earth.]

XI. The *tenth* opinion attributes to the Earth both the diurnal and the annual motion, but nevertheless does not take away from the fixed stars their proper motion eastward, still less from the planets. So, in the end, *Philips van Lansbergen*, in his *Tables*, precept 11; *Jacob van Lansbergen*, physician, in the *Apologia* for Philips, against Froidmont and Morinus [Jean-Baptiste Morin]; and *Ismaël Boulliau*, book 1 of the *Astronomia Philolaica*, chapter 2, for the reasons I set out in book 6, chapter 18, number 14. They differ, however, in that Lansbergen makes the motion of the fixed stars upon the poles of the ecliptic unequal, because of the unequal motion of the equinoctial points, whereas Boulliau makes it equal. But neither this opinion nor the ninth may we follow, by the divine Scriptures or by the decrees of the Church.

[Margin: 11. The opinion setting out [?] everything by a simple motion along spirals and gyres.]

XII. The *eleventh* opinion is very similar to the seventh, but it does not make the primum mobile the eighth sphere. Instead it says that all the proper motions which appear towards the east, in the fixed stars as well as in the planets, can be reconciled with their diurnal motion towards the west by a single oblique motion towards the west, made screw-wise [cochleatim] along helices and spirals, or helicoid spirals. Along these the stars do not complete exactly the same diurnal circle, nor return today to the same point of the meridian or horizon at which they stood yesterday, but bend somewhat towards the sides of the world,

towards the poles — yet in such a way that the fixed stars come round to the same meridian more quickly than Saturn, and Saturn more quickly than Jupiter, and so for the rest. Understand this of the planets when they are direct; for if they become stationary, they then appear just as swift as the fixed stars, and when they are commonly called retrograde they are then swifter than the fixed stars, and slower only when direct. Again, the planets are carried along this gyrating line in such a way that they move now higher, now lower. This is taught, though in other words, by *Scotus*, in 2, distinction 14, question 2; *Hurtadus*, disputation 2 on the heavens, section 3; *Mastrius and Bellutus*, disputation 2 on the heavens, question 4, article 1; *Cabeo*, on book 1 of the *Meteorologica*, text 38, question 2; *Amicus*, treatise 5 on the heavens, question 6, doubt 9, article 3, who in article 2 had adduced for this view Philoponus, Alexander, Vicomercatus, Galtus, Alvernia and Maior; *Arriaga*, the single disputation on the heavens, sections 4 and 5; *Oviedus*, the single controversy on the heavens, point 4; *Ioannes Poncius*, disputation 22 of the *Physics*, question 9, conclusion 3; and *Balthasar Tellez*, disputation 45 of the *Physics*, section 3, number 6. Of the same opinion, for the most part, were Alpetragius, Achillinus, Aliacensis and Delphinus, cited in numbers 5 and 6, and before them Anaxagoras, Democritus and Cleanthes, of whom number 7 speaks. Scotus, Mastrius and Bellutus, however, speak in such a way that they seem to admit, with Alpetragius, a primum mobile distinct from the eighth sphere. Tellez, on the other hand, does not recognise that first motion as really taking place in any body, but holds it to be merely imaginary, and that neither the fixed stars nor the planets exactly attain its measure. Others do not explain clearly enough whether there is any motion of the primum mobile, real or imaginary, which the fixed stars emulate but do not attain by their diurnal motion; and those who retain solid heavens, such as Amicus and Mastrius, can defend the spirals just mentioned only with difficulty.

[Margin: 12. The opinion of imperceptible [?] brief pauses.]

XIII. The *twelfth* opinion is the one I set out in book 6, chapter 18, number 16, as devised by me; but after many months I found it indicated by Amicus, treatise 5 on the heavens, question 6, doubt 9, article 3, in these words: *Fourth, others, thinking that those motions are two, say that they are not exercised simultaneously but by turns: while the Intelligence moves the heaven towards the poles of the Zodiac, it does not move it from east to west; and because that lateral motion takes place in the twinkling of an eye, the orb does not appear to cease from its diurnal motion. But this way of speaking, as it lacks a suitable author, so it cannot be probable; it is therefore more reasonable that there is really one motion arising from a diverse impetus, or a single gyrating one, but not perfectly gyrating.* Yet if that interruption by imperceptible brief pauses [per morulas insensibiles] cannot be refuted by any observation, it is not altogether improbable. *Poncius* touched on the same idea above, when he said: *It is manifest that something can be moved at once, at the same time, without any intermission perceptible to our senses, by two motions, one from east to west and the other from west to east.* How I explained this mode is clear from what was said in that number 16.

So many ways, then, and such remarkable ones — some worthy of human ingenuity, some unworthy of it — have been attempted for reconciling these two motions. What our own opinion is, although it was indicated in book 6, chapter 18, from number 15, must nevertheless be set out more fully here, through the following conclusions.

PRIMA CONCLVSIO.

First Conclusion.

[Margin: 1st conclusion.]

Both the wandering and the non-wandering stars can be moved westward by the motion of a primum mobile, or after the pattern of its motion [à motu vel ad motum], really distinct from their own heaven or from the stars; and meanwhile they can at the same time be moved, truly or apparently, by a proper motion eastward, without any physical contradiction.

XIV. For if there were any contradiction, it would lie either in the moving and movable bodies themselves — that they could not exist, or could not be joined or assigned together for this purpose — or in the very manner of producing both motions. But the contradiction arises on neither head; therefore what the conclusion asserts can come about. As to the first head, various celestial bodies can be assigned to perform the office of the primum mobile.

[Margin: 1st body for the primum mobile.]

First, this can be a watery heaven, made of the waters which, as we taught in section 1, chapter 2, question 3, and chapter 3, conclusion 3, are above the heavens, according to the more probable opinion of many Fathers, consonant with the letter of the divine books. This heaven does not flow away this way and that, because of its equal distance from the centre of heavy things, or because there it is outside the place of heavy and light things; and yet the whole of it may be moved in the space of 24 hours by one Intelligence, or by several if need be.

[Margin: 2nd body.]

Second, this can be an icy or crystalline heaven above the sphere of the fixed stars, as Delphinus and Clavius posit. This agrees with those Doctors and Fathers who believed that the waters above the heaven of the fixed stars were consolidated by God in the manner of ice or crystal, according to what was said in section 1, chapter 2, number 8 — such were Iosephus Hebraeus [Flavius Josephus], Pope Clement, Severianus, Anselmus Laudunensis, Strabus, Bede and Petrus Comestor. This heaven too could be revolved westward in the space of 24 hours by one Intelligence or by several.

[Margin: 3rd body.]

Third, it could be the heaven of the fixed stars itself, but fluid, which would move the fixed stars westward immediately, and the planets by means of the heaven of the planets, whether fluid or solid.

[Margin: 4th body.]

Fourth, it could be the heaven of the planets itself, whether fluid or solid, which would itself move the planets immediately, and indeed the fixed stars too, which it would touch immediately with its convex surface; or would move them and all the rest by moving the heaven of the fixed stars, whether fluid or solid.

[Margin: 5th body.]

Fifth, some body could be assumed by one Intelligence — or a body carried round, though not properly assumed, which would not be a heaven — and the Intelligence could lead it round the Firmament in the space of 24 hours, as a sensible exemplar of universal time, in imitation of which the fixed stars and the planets would have to be moved by their Intelligences, either immediately or through intermediate orbs. In the same way, some say that in the first three days that primordial light, which made three natural days, was a luminous cloud.

[Margin: 6th body.]

Sixth, without the motion of any body round the heaven, there could be various clocks measuring a time of 24 hours, far more excellent than ours, which the movers of the fixed stars and of the heavens would likewise have to imitate in their motion westward.

[Margin: 7th body.]

Seventh, above the heaven of the fixed stars, or in it, there could be a kind of equator, like a girdle of the world, made of solid matter and really distinct from that heaven, which would be moved westward by an Intelligence in the space of 24 hours. For among these bodies listed there is nothing that could not have come about physically. And the immediate conjunction of the first two with the heaven of the fixed stars neither involves a contradiction nor is absurd in astronomy. For no sphere is required between that heaven and the primum mobile to account for trepidation, or for a libration in longitude or in latitude; for we have already taught, as much the truer view, that the obliquity of the ecliptic does not vary (namely in book 3, chapter 27), that the equinoctial or tropical year is not unequal (namely in book 3, chapter 30), and that the precession of the equinoxes, or the motion of the fixed stars, is neither retrograde nor anomalous (namely in book 3, chapter 28, and book 6, chapter 17).

[Margin: 1st mode.] [Margin: 2nd mode.]

XV. As to the manner of moving other heavens or the stars westward in such a way that they nevertheless seem, truly or apparently, to move somewhat towards the east: the *first* could be by imperceptible brief pauses, already set out in book 6, chapter 18, number 16, and indicated in this chapter, number 13. The *second* could be by a continuous sweeping-along [raptus] — whether it should be called a drawing, a pushing, a carrying or a leading-round — which, however, because of the resistance of the heaven or star swept along, would not move it westward as swiftly as it would have moved it if nothing resisted it; and so it could not, within precisely those 24 hours in which the primum

mobile itself would complete its whole revolution, revolve the lower globes as well to the same meridian or horizon.

[Margin: 3rd mode.]

The *third* is if the movers of the sphere of the fixed stars and of the planets try to imitate the motion of the watery or crystalline heaven, or of a body or clock equivalent to those very heavens, but do not revolve their globe to the same meridian in the space of 24 hours, and reach it each day a little later; and this along spiral helices, as we said in number 12 when explaining the 11th opinion.

[Margin: 4th mode.]

The *fourth* is if the heaven both of the planets and of the fixed stars is fluid and is moved by one or more Intelligences in the space of 24 hours, while in imitation of it other Intelligences move the planets and the fixed stars westward indeed, but later each day, always falling short towards the east. And so that there need not be as many Intelligences multiplied as there are fixed stars, the fixed stars could be bound to one another as if in a kind of solid network invisible to us, as we said in book 6, chapter 18, number 17, under the 2nd mode. For in none of these 4 modes is there any contradiction, nor two continuous and mutually contrary motions, but a single motion — slower, however, or less swift, than the motion of the primum mobile.

SECVNDA CONCLVSIO.

Second Conclusion.

[Margin: 2nd conclusion.]

Yet without any mobile body really distinct from the star-bearing heavens, or from the stars themselves, that twofold motion which appears in all the stars — one westward, the other eastward — can come about and be explained, the other motions of the heavenly bodies also being preserved, without any physical contradiction.

[Margin: 1st mode.]

XVI. This is proved by the modes indicated. The *first* of them is if one or more Intelligences, moving the sphere of the fixed stars from east to west, have in their impressed species, infused by God, a perfect idea of a time of 24 hours — not hours such as make up the days we usually measure by the revolution of the Sun or of the fixed stars, but somewhat shorter ones, such as there would be if a primum mobile distinct from the star-bearing heavens and from the stars really existed. In moving the orb of the fixed stars, however, they exceed the perfect quantity of that intellectual measure, and so revolve it to the same meridian more slowly, that is, in a time a little longer than that of the 24 intellectual hours — such, perhaps, as was the time of the first three days. The Intelligences of the remaining orbs or globes, on the other hand, would take as the measure of the motion they are to perform not that intellectual day but the day made by a single revolution of the fixed stars — yet in such a way that they too would revolve their globes somewhat later, and the later the farther they are from the fixed stars. Accordingly, with respect to the planets, the sphere of the fixed stars

would be a primum mobile not physical, but after the manner of a moral, or as it were exemplary, cause. All these motions, however, would have to take place along the spirals and gyres of which I spoke in number 12, so that the variety of declinations and latitudes would be preserved; and when the planets are called stationary they would have to be moved just as swiftly as the fixed stars, but when retrograde they would have to be driven by their Intelligences somewhat more swiftly than the fixed stars.

[Margin: 2nd mode.]

The *second* mode would be if all the Intelligences, in the motion already mentioned, of the fixed stars as well as of the planets, westward — yet along spirals, etc. — looked to that single time, imaginary for us but mental or intellectual for them, shining in their impressed species and infused by God from the beginning of the world.

[Margin: Imitating the motion of the fixed stars by a mechanical experiment.]

XVII. But since to some the motion of the planets in a fluid heaven along the spirals just mentioned seems easy, but that of the fixed stars difficult, because they are accustomed to their own me- chanical globe, resting on poles fixed in the meridian — let them, I ask, use a star-bearing globe or Aratean sphere that is not fixed by its poles, or by any axis, to the horizon or the meridian, but is supported by some concave vessel, or rests on water or sand. Let them fix a small nail in any one point of it, or in a star painted on the globe, and, grasping this as a handle, lead the globe round towards the east, but bending it spirally and imperceptibly towards the poles. They will see that at the motion of one point or star all the other points and the other fixed stars are moved likewise, and change their declinations. And if someone has a small clock which meanwhile, by a kind of fiction, he uses as the measure of one revolution, let him move the globe in such a way that a star once chosen does not reach the meridian of the sphere until somewhat later. From this he will learn how much easier it is for one Intelligence, or several, to move all the fixed stars together spirally, or following the motion of one of them — whether because they are fixed to a solid firmament, or because, if the firmament is supposed fluid, they are nevertheless bound together by some indissoluble bond.

TERTIA CONCLVSIO.

Third Conclusion.

[Margin: 3rd conclusion.]

It is more probable that there is no body which is the primum mobile, nor two motions produced in the stars at the same time towards opposite quarters of the world, but a single motion towards the west along helicoid spirals — that of the fixed stars in a solid heaven, that of the planets in a fluid one; and that the office of the primum mobile is performed by an intelligible time, that is, an idea of the diurnal motion infused into the mind of every moving Intelligence.

XVIII. The first part is proved as follows. As is commonplace in the schools, what can be done by fewer means is done in vain by more; and, as *Ptolemy* advised (*Almagest* book 13, chapter 2, whose words I quoted in chapter 2, number 3), that motion is to be attributed to the celestial bodies which answers the phenomena while being as simple as possible and exposed to the fewest possible hindrances. Such is the motion we stated in the conclusion. For it takes place along a single spiral line, adaptable to all the motions of the stars, and capable of being traced by Intelligences that have the highest skill concerning the path and course along which they must carry the stars round by God's prescription. Nor can any violence from a sweeping-along, or any resistance from a medium or surrounding body, be feared, since the fluid heaven of the planets yields both to the planets and to the concave surface of the heaven of the fixed stars, above which the watery heaven is, and is fluid as well. Next, even if some body were posited as the primum mobile, whose motion at least the Intelligence would have to imitate, its motion would nevertheless have to be understood by the Intelligence, and so the Intelligence would have to have at least expressed species of it in its mind; and if it contemplated this by another, as it were reflex, act, it could use it as an impressed species and idea of that motion. Therefore, if through these species, which we cannot do without, the Angels can achieve whatever they would do with them and with that mobile body, then that motion of a distinct orb or body is certainly multiplied in vain. Indeed, not only in vain, but also against the dignity of the angelic nature. For if that musician is more excellent who knows how to sing, or to strike the strings, in harmonic measure, using the time he has in his mind, and has no need of any sensible beating of the hand or external sign to regulate his voice, then certainly the mode we have ascribed to the Intelligences is more excellent too, since they need no corporeal clepsydra, as it were, in order to move skilfully and harmoniously the stars and globes committed to them, and to perform their dances, so to speak, to this secret harmony of the world.

[Margin: 2nd part of the conclusion.]

The *second* part, on the distinction of a solid heaven from a fluid one, has already been proved in section 1, chapter 7, number 21. It is confirmed by this: in this way it is much easier for the fixed stars to keep their distances from one another perpetually, and to be moved uniformly, following the motion of one or a few of them, by one or a few Intelligences, than if they were moved in a fluid heaven.

[Margin: 3rd part of the conclusion.]

The *third* part, on the intellectual time known by each Intelligence and used as the immediate measure of the motion to be performed, is proved because it cannot be denied that this time is known by them. They would therefore be supposed in vain to need that sensible time by which the heaven of the fixed stars is moved; and it is better that there be one measure common to all of them, to which they may adjust their motions and revolutions. For just as they also know that time which did not exist before the world but could have

existed, so they know that diurnal time by which the ninth heaven would be moved if it were the primum mobile, and how much more swiftly it would reach the meridian than the fixed stars or the planets. They can therefore use this immediately; and it is more fitting that they should need no other sensible motion and time, granted that they must move sensible bodies. Nor is it absurd that the first and most universal time, with respect to an intellectual nature, should really be only intellectual — or, as they say, exist intentionally — and exist only objectively, in the angelic mind or in ours. For this is what happens with very many other ideas which we use in artefacts and sensible works. *For the house which is outside the soul comes from the house which is within the soul*, says the Philosopher (*Metaphysics* 7, text 23) — that is, from the idea and impressed species, which shines objectively in our mind and is the image of the house to be made. Therefore, if that architect would be more perfect who knew how, and was able, to direct the builders without a mechanical and external model or exemplar, or to build with his own hands, then the motion of an Intelligence will also be more perfect if it needs no external and sensible exemplar to perform the diurnal motion.

[Margin: What if the primum mobile is some sensible body?]

XIX. But if someone nevertheless requires that the time which is the universal measure of all motions, and as it were the norm of the rest, should be — or should at least once have been — the motion of some sensible body, or its number or measure, I would urge on him three more probable modes.

[Margin: 1st mode, by a simple equator.]

The *first* is the one I indicated in number 14, in the seventh place: namely by a kind of equator in the celestial globe, or above it, divided into 360 degrees and subdivided into minutes — or rather directly into minutes — not such as ours are, but into far finer particles, fit for discerning all the minutiae and little differences of the motions to be performed in the fixed stars and planets from the beginning of the world to its end. These would nevertheless be very large, on account of the vastness of that girdle, if they were compared with the minutes, or even the degrees, of our spheres or astronomical instruments. For if that motion of 24 hours could be represented by the motion of this girdle, wrought of solid matter, the whole machine of some ninth, tenth or eleventh heaven would be supposed in vain to be moved in order to provide this single motion. Supposing, then, that this motion is produced by a single Intelligence revolving that equator to the same meridian, the remaining Intelligences would have to move the fixed stars and the planets westward spirally, or screw-wise, in such a way that, when the beginning of the equator reaches some one meridian — say, that of Jerusalem — a fixed star which on the previous day had been under the initial point of the equator would on the following day not yet have been brought with its centre to the same meridian, and much less Saturn when direct, etc.

[Margin: 2nd mode, by the crystalline heaven.]

The *second* mode is that we choose that watery or crystalline heaven which is above the Firmament as the body which, by its own motion produced by an Intelligence, represents the motion of the primum mobile. In this way it will be confirmed that those waters were not placed above the Firmament by God on the second day in vain — granted that others have assigned many other purposes, concerning which, section 1, chapter 2, number 10. The *third* mode could be through the mere memory of the primordial light made by God on the first day of the world, and of its motion or successive production, by virtue of which the first three days of the world were completed. For there have been those who said that this light, or even the Sun made on the first day, had no other motion than that of the primum mobile, and that on the fourth day a proper motion was added to the Sun and to the other stars — according to what was said in section 1, partly in chapter 1, number 34, in reporting the opinion of Aegidius, and partly in chapter 4, number 3. In that case that first natural day, or even the first three days, would have been the most perfect and the shortest of all, since that light revolved most swiftly — no less swiftly than the equator of the primum mobile is now said to be moved in the treatises on the sphere. Therefore the memory of that day, or of those days, would suffice for the Angels to be able to revolve their spheres or stars to the same meridian in a time not so short, but a little longer. Whatever else seems to need adding to this subtle point I shall indicate shortly, in the scholia.

SCHOLIA.

Scholia.

[Margin: Whether two contrary [?] motions can be given.]

I. In connection with reconciling the motion of the primum mobile with the proper motion of the stars towards the east, physicists customarily dispute whether there can be two continuous and contrary local motions — that is, motions by which one and the same mobile body, with respect to the same part of itself, is carried towards one quarter of the world and at the same time towards the opposite one: if not *per se* and by the force of one and the same moving principle, then at least *per accidens* and by the force of different moving principles. This controversy is touched on by Maior, on book 2, distinction 24, question 1; Mayronus, in the same place, question 3; Girolamo Fracastoro, *Homocentrica*, section 1, chapter 8; Clavius, on the *Sphere*, page 52; Rubius and the Coimbra commentators [Conimbricenses] on *De caelo* book 2, chapter 5, question 4, article 2; Mastri and Belluto, disputation 2 on *De caelo*, question 4, article 1, numbers 129 and 130; Amicus, treatise 5 on *De caelo*, question 6, doubt 7, article 3; Hurtadus, disputation 2 on *De caelo*, section 3, paragraph 12; Arriaga, the single disputation on *De caelo*, section 5, number 56; Oviedus, the single controversy on *De caelo*, point 4, number 6; Poncius, disputation 22 on the *Physics*, question 9, number 94; and Tellez, disputation 40 on the *Physics*, section 2, numbers 4 and 5.

Of these, Poncius and Tellez seem to grant two contrary motions, one *per se* or from within, the other *per accidens* and from without. They use the now hackneyed example of an ant or a fly crawling on a wheel that is turned round in the contrary direction, or of a man walking in a ship towards the east, from the prow to the stern, while the prow of the ship is carried towards the west. What Tellez adds about a stone that would naturally descend along a straight line but is carried sideways by an external impulse, and so is moved by two motions, is not to the point, since these are not two contrary motions, that is, motions towards contrary termini. More to the point is a stone drawn by a rope from prow to stern by someone sitting on the bank of the river, while the ship is meanwhile carried by the river in the opposite direction.

The rest of the authors already mentioned, however, and finally Poncius himself, reply that it is naturally impossible for the same part of a subject to be moved by two simply contrary motions — that is, in such a way that at the same time it approaches the same fixed point of the world and recedes from it. For although metaphysically the contradiction seems to be removed by distinguishing two different moving principles, physically this is nevertheless incompatible with the nature of local motion. Local motion is an action by virtue of which either the whole mobile body or a part of it recedes from one place as its *terminus a quo* and approaches another as its *terminus ad quem* along the same line, and acquires another *where* [ubi] distinct from the former one. But it is naturally impossible for the same mobile body to be in two adequate places at the same time, and to approach, actually and in reality, the terminus from which it recedes: for receding includes or connotes the privation of approach and of local presence, and a privation and the form opposed to it cannot physically exist together in the same instant of time. Granted, if a body were replicated by divine omnipotence, it could, so replicated, be moved in opposite directions. The same thing can, however, be moved with respect to the same part of the subject by a twofold impetus, one of which by its nature pushes or draws towards the east and the other towards the west — but in such a way that only one of them prevails and actually moves it in a single direction, though more slowly than if it were not retarded by the other impetus. For if neither prevailed, the mobile body would be moved in neither direction. And so they deny that there are two motions: there is a single one, only slower. In the motions of animals, however, which lift their legs as they walk, a motion upward and downward is mixed in, which is neither contrary nor directly opposed to the motion of the ship or the wheel. Although this reply is good, and one I have accepted elsewhere, it can nevertheless be explained by a still more perfect distinction, as will be done shortly in the following scholium.

[Margin: Explanation of two opposite motions that are compossible.]

II. Two things, then, must be noted and distinguished in the motion either of animals, moved from within, or of inanimate things, moved from without, that are moved not over an immobile place but over a mobile one, or within it as within a vessel. *First*, in such a motion a twofold *terminus ad quem* can

be considered: one fixed and immobile, in a determinate part or point of the world; the other mobile, in the vessel and place itself — a terminus that is moved with the motion of the vessel, as a part with the motion of the whole. *Secondly*, motion towards some terminus, or in its direction, that is relative or respective, or comparative, or even hypothetical, must be distinguished from absolute motion, by which that terminus is approached.

Therefore, suppose some body contained within some vessel is carried with the motion of the vessel towards the west, and meanwhile that body is carried by another motive principle towards the eastern part of the vessel. If each impetus is equal, it will indeed approach the mobile eastern terminus by an absolute motion; but it will neither recede from the immobile eastern terminus nor approach it, and will remain in the same place, absolutely. But if the impetus by which the vessel is carried to the west prevails, that body will absolutely recede from the fixed eastern terminus and absolutely approach the mobile eastern terminus. It will not approach the immobile eastern terminus except respectively, inasmuch as its proper motion is directed towards the east; or comparatively, because it recedes from it less than if it were moved by no proper motion within the vessel or upon it; or, finally, hypothetically, inasmuch as it would have approached it if it had used its own motion alone and the vessel had stood still. Finally, if the impetus of that body prevails, it will either approach or pass beyond the fixed eastern terminus absolutely, but will recede from it only respectively, or comparatively, or hypothetically.

To assist the imagination, it is convenient to set this out in the accompanying diagram. In it, let AEB be a stretch of river, bisected at E; let its half AE be equal to the length of the ship CCDC,

Diagram. In the right column: a horizontal base line, the stretch of river, carries five points; above it a row of ship-positions, joined to the base line by dotted verticals and to one another by three curved arcs, concave upward; above these, a row of fixed points of the world, each of the first four marked with a small dot. The man O stands below H.

- G (top row, far left): a fixed point of the world, the eastern terminus
- Q (top row, second): a fixed point
- H (top row, centre): a fixed point
- L (top row, fourth): a fixed point
- K (top row, far right): a fixed point, the western terminus
- O (below H): the man
- C (middle row, far left, above A): the stern
- C (middle row, second, above M): the stern
- DC (middle row, centre, above E): prow and stern
- D (middle row, fourth, above I): a ship-point
- D (middle row, far right, above B): the prow
- A (base line, far left): end of the river stretch
- M (base line, second): midpoint of AE
- E (base line, centre): the point of bisection

- I (base line, fourth): a point on EB
- B (base line, far right): end of the river stretch

and the other half EB to the length of the same ship DC DD, now moved from the place under the fixed points of the world CQH [?] to the place under the fixed points HLK. But when the midpoint of its hull has covered half the space AE, namely the space ME, let the same ship be under the fixed points QHL; and let G be the eastern terminus, and K the western.

[Margin: 1st case.]

Now, *first*, at the beginning of the whole motion let the man O be at the prow D, under H, and let him begin to walk towards the stern C — towards G — so that in one minute of time, in which the ship, carried by the river, has traversed the whole space equal to its own length and has come under the points HLK, he has reached the stern C. For he will still be under the same fixed point H under which he was at the beginning of the motion, because the stern of the ship, which he has reached, is under it. Therefore, although he has moved absolutely and has approached the mobile terminus, that is, the stern, he has approached the immobile terminus G absolutely not one whit more — the terminus he would have approached had the ship not been moved.

[Margin: 2nd case.]

Secondly, imagine that the man O, while the whole ship in one minute of time leaves the whole space AE, which lies under the fixed space GQH, moves twice as slowly, and so in one minute gets from the prow to the middle of the ship. For he will be at D, under the point L. Therefore, although he has approached the stern DC absolutely, and indeed his walking was respectively directed towards G, he has nevertheless absolutely receded from G, the fixed eastern point, and approached K, the western terminus, since at the beginning of the motion he was under H. But if the ship had meanwhile not been moved forward at all, he would have come from DC to C, under Q; this motion, however, is only hypothetical. Conversely, if only the ship had been moved forward, he, not walking at all, would at the end of the motion have been at the prow D, under K. Therefore, since because of the walking just mentioned he is at D, under L, he has indeed receded from G absolutely; but comparatively — with respect to the recession that would have put him at D, under K — he has approached it, because he has receded less.

[Margin: 3rd case.]

Thirdly, while the man O runs through the whole ship from prow to stern in one minute of time, let the ship, twice as slow, cover half of its own length, the space ME, so that, whereas the prow was under H and the stern under G, at the end of the motion the prow is under L and the stern under Q. That man will then be under Q; and so he has indeed approached both termini absolutely — the mobile one, of the stern, and the immobile one, G; but from the immobile G he has receded only comparatively or hypothetically.

The motions of an ant on a wheel turned round in the opposite direction, and of water stirred towards the left with a finger in a vessel revolved towards

the right, and similar cases, are to be understood proportionally. For in truth, in the ant and in the water there are two motions fused into one, which are not contrary, since their *termini ad quos* are not the same, one being fixed, the other mobile; nor is there, with respect to the fixed one, an absolute approach and recession of the same part, etc.

[Margin: Whether we have any example of the first motion?]

III. You will ask whether, of the motion of the primum mobile — which in our Idea we assign to the rational equator, and which, as we said above, shines in the minds of the Intelligences that move the heaven of the fixed stars and the planets — we can have some sensible speci- men? For commonly we have no other exemplar than the motion of a single fixed star revolved once from a meridian back to the same meridian; and still more commonly we use the revolution of the Sun to the same meridian or horizon. I reply as follows. By what I said in book 6, chapter 16, any fixed star, in my view, completes one degree of its own apparent proper motion in 72 years: that is, when 72 Julian solar years have elapsed, a fixed star — Sirius or Spica, for example — stands one degree towards the east, in its parallel to the equator, from the meridian under which it stood at the noon from which the year, and the start of the 72 years, was taken. It follows that in one day it completes, of such apparent motion, $8''' \; 13'''' \; 9^{v}$, with a further small fraction of 3/13. Now, to complete $8'''$ of the equator a time of 32 fourths is required, that is, very nearly half of a single third. We would therefore need a pendulum that by one simple vibration would show us the time of half a third; we would measure with it the revolution of one and the same fixed star from a meridian back to the same meridian, and subtract a single vibration from that number of vibrations, so as to have some specimen of that ideal day. But a pendulum of this kind is not possible for us, as you will gather from what we said in book 2, chapters 20 and 21; for the vibrations of a pendulum each of which shows ten thirds of time can scarcely be counted. In vain, therefore, would anyone try to construct a clock that would show us such a day and distinguish it from the day produced by the revolution of a single fixed star to the meridian. Granted, we can gather the differences of such days and years by reasoning and with the help of logistic; and for astronomical practice and the most subtle observations it is more than enough to use the day that a single fixed star shows us by its revolution, since it is imperceptibly longer than one day of the rational primum mobile. But we have treated the differences of these days from one another and from the solar day with sufficient subtlety in book 3, chapter 21.

CAPVT IV.

Chapter 4.

Whether the proper motion of the stars is, per se and by the primary intention of nature — or rather of God and of the moving Intelligence — equal, or rather unequal; yet ordered and regularly unequal, and sufficient to manifest God and His Providence.

[Margin: Restriction and state of the question.]

I. I am not raising the question of the motion of the primum mobile, for all admit that it is most equable and uniform, as being the most universal rule of all the motions that occur in this sensible world. Of it hold those words of the Philosopher (*De caelo* 2, chapter 6, text 35): *Next we must go through the question of the motion of the heaven, that it is regular and not irregular. I say this of the first heaven and of the first motion [latio].* And speaking of this same motion (*Physics* 8, text 76): *For since*, he says, *circular motion is the measure of motions, it must itself be first; for all things are measured by what is first; and because it is first it is the measure of the others; moreover, it can also be regular.* Nor do I raise a doubt about the proper motion of the fixed stars in longitude, for I already suppose it to be equal, from what was said in book 3, chapters 28 and 30, and book 6, chapter 17. There remains, therefore, the controversy about the motion of the planets, which is compounded of several mixed kinds — namely in longitude, latitude, and depth or altitude. Yet about this, too, there is no doubt that it appears unequal to us, and that, with respect to the centre of the terrestrial surface, it passes through unequal parts of the heaven in equal times. For I believe this is now established by the clearest experiments of observation, and that the reader has been persuaded of it by what was said — of the Sun in book 3 from chapter 13 on, of the Moon in book 4 from chapter 18 on, and of the remaining planets in book 7, section 1, chapter 7, and sections 2 and 3.

We therefore ask about the motion of the planets *per se* and from the nature of the mobile planets — or rather from the intention of God, the Founder and first institutor of such motions, and hence from the intention of the Intelligence that moves the planet and that, of course, complies with the divine intention: namely, whether it is unequal as it appears; or whether it merely seems unequal to us *per accidens*, placed as we are outside the place from which it ought to be viewed, while *per se*, and viewed from where it ought to be viewed, it is equal and uniform. Just so a rule may be straight in itself and yet, like an oar, appear bent because of refraction in water; or a man may in reality be hairy and have a rather long beard, yet, seen from far off, appear smooth and beardless, because at too great a distance the hairs do not stand out or do not appear.

[Margin: 1st opinion [?], for the equality of the celestial motions.]

The first opinion was that the motions of all the stars are equal in their circles. For Anaximenes *said that the stars turn in the same way both above and around the Earth*, as Plutarch reports (*De placitis* book 2, chapter 16); and Aristotle (*Physics* 8, text 76, and *De caelo* 2, from text 35 on) adduces such arguments for the regularity of the first motion of the highest heaven that they hold equally for every circular motion that occurs in the heaven.

[Margin: Anaximenes.]

[Margin: Aristotle.]

For he says that it is regular for this reason: being circular, it has no beginning or end by approaching which it would have to be carried faster. For he says in that text 76: *Moreover, it is the circular alone that can be regular; for things that come*

about along a straight line are carried irregularly from the beginning and towards the end — for all things are carried faster the farther they are from that which is at rest. Of the circular alone, however, neither the beginning nor the end is by nature within it, but outside. There he is speaking of the purely natural motions of simple bodies. But in *De caelo* 2, text 35, speaking more universally, he says: *For if it were moved irregularly, it is clear that there would be in it an intensification, an acme [status] and a remission of its motion; for every irregular motion has remission, intensification and acme. And the acme is either at the terminus from which the mobile body is carried, or at the terminus to which it is carried, or in the middle. In things carried by nature, rest is at the terminus to which; in things carried violently or against nature, rest is at the terminus from which; and in projectiles, in the middle. But circular motion has no terminus from which or to which, nor a middle: for it has simply no beginning, no end and no middle; in time it is everlasting, and in length it is drawn back into itself and in no way interrupted. Therefore, if there is no acme of its motion, there will be no irregularity either; for irregularity arises through intensification and remission.* And this is Aristotle's first argument.

[Margin: 2nd argument of Aristotle.]

The second he adds in text 36, taken from the exclusion of the causes of irregularity. For since, he says, everything that is moved is moved by another, the irregularity of a motion must arise either from what moves or from what is moved; but in a celestial body it can arise from neither source, because both what moves and what is moved are incorruptible, simple and wholly immutable.

[Margin: 3rd argument of Aristotle.]

The *third* argument is adduced in text 37, thus: either the whole period of the celestial motion would be unequal, now slower, now faster, or its parts would be. But its parts have not yet been observed to have become faster or slower; for since an infinite time has preceded in which this motion has existed, the distance of the stars would by now have become infinite. Nor could the whole period be changed and become slower: for remission arises through incapacity, and incapacity is against nature; but in the first bodies there is nothing against nature (for they are simple and unmixed, and in their proper region, and nothing is contrary to them). Therefore there will be no incapacity, and consequently neither remission nor intensification, which connotes remission before it, if not after it. Besides, says Aristotle in text 38, it is absurd that what moves should be incapable for an infinite time and in turn capable for another infinite time; for all things in the infinite are indeterminate.

It is therefore clear that Aristotle's arguments apply not only to the motion of the primum mobile, or to that of the highest heaven, but to every motion of the planets, which he held to be circular and eternal (*Metaphysics* 12, text 43). But since he had said in *De caelo* book 1, text 23, *For the motion of a simple body must be simple*, and since astronomers use "simple motion" for one intermediate between fast and slow, that is, for equal motion, there spread from this into the schools of the physicists and astronomers this quasi-Peripatetic axiom: *the*

motion of a simple body, such as the heaven is, must be simple and equal, that is, regular.

[Margin: Simple and regular motion are not the same.]

But this, certainly, in that place is not what Aristotle meant; for in the same text he at once adds: *But we say that these alone are simple: the one that is circular, and the one that comes about along a straight line; and of the latter there are two parts, one away from the middle, the other towards the middle.* Therefore the motion of the elements, which are themselves simple bodies too — whether it is away from the middle of the universe, as is the motion of light things, or towards the middle, as is the motion of heavy things — is a simple motion. And yet the same Philosopher teaches (*Physics* 8, text 76, and *De caelo* 2, text 35), as we have already said, that this motion is irregular, and becomes faster and faster, and more intense from more remiss, the nearer they come to the place of their natural rest — granted that Plato, in the *Timaeus*, denied that the motion produced by the elements along a straight line is simple. Although, then, it was an axiom among most Peripatetics that a motion regular and uniform *per se* belongs to the heaven, as a simple body, it was nevertheless wrongly derived from the name "simple motion".

[Margin: Plato.]

Plato too, as Theon of Smyrna reports in his *Astronomy*, adhered to the Pythagoreans and held that the celestial motions are circular, regular and equal.

[Margin: Ptolemy's view.]

II. Among the astronomers, their chief, Ptolemy (*Almagest* book 3, chapter 3), expressly affirms that equality *per se* belongs to the celestial and everlasting bodies; for that chapter begins thus: *Since it follows that we must demonstrate the apparent inequality in the motion of the Sun, it must be stated in advance, in general, that the motions of the wandering stars too, in the order of the signs, no less than the motion of the whole universe against the order of the signs, are all by their nature equal and circular: that is, all the lines that are understood to carry the stars or their circles round intercept, in all simply equal times, equal angles at the centres of each circulation. The inequalities that appear in them arise from the positions and arrangements of the circles by which they are moved and in whose spheres they are enclosed; and nothing alien to their everlastingness in any way actually happens on account of the confused order of the appearances.* He attributes the apparent inequality of the Sun either to our eye being placed outside the centre of the circle that carries the Sun — a circle described from a centre other than the Earth's — or to the composition of a concentric with an epicycle carrying the Sun. Hence, if our eye were at the centre of the circle carrying the Sun, it would see equal portions of the ecliptic traversed by the Sun in equal times. And in book 9, chapter 2, he declares: *Since it is our purpose (as we did for the Sun and the Moon) to demonstrate for the five planets too that all their apparent inequalities arise through equal and circular motions — for such motions befit the nature of divine bodies, from which disorder and irregularity [?] are far removed — we must think highly of whatever we achieve in*

this matter. Ptolemy was followed thereafter by the Arabs and by very many astronomers, whether upholders of eccentrics and epicycles or of homocentrics.

[Margin: Fracastoro's opinion.]

For Girolamo Fracastoro himself, too, in the *Homocentrica*, section 2, chapter 20, has these words: *The revolutions of this inequality are not equal to one another, neither the whole nor their parts, etc. But this is per accidens; for per se they are all equal, and if they are measured by the mean motion of the first circitor.*

[Margin: Copernicus's view.]

How tenaciously Copernicus asserted the equality of the celestial motions is gathered from this: in Ptolemy he could not stomach that the Moon and the five lesser planets should have, besides the epicycle, two eccentrics — one of which would carry the centre of the epicycle, but unequally, while the other would not carry it, and yet the centre of the epicycle would be moved equally with respect to that eccentric's centre. This second eccentric the astronomers call the equant, and of it we have said enough in book 7, section 2, chapter 1, scholium 1. For Copernicus thought it absurd that a celestial motion should beg its equality from a foreign centre, that is, from a centre from which the circle of such a motion was not described. Copernicus's words in book 4, chapter 2, on Ptolemy's lunar hypothesis, are these: *The motion of the epicycle, then, is unequal on its own eccentric, which it describes. If this is so, what shall we answer to the axiom that the motion of the celestial bodies is equal, and seems equal only as to appearance, if the motion of the epicycle, apparently equal, is in reality unequal, and the very opposite of the principle laid down and assumed comes about? But if you say that it moves equally about the Earth's centre, and that this is enough to preserve the equality, what kind of equality will that be, in a foreign circle in which its motion does not take place, rather than on its own eccentric? Thus indeed we wonder, etc.* And a little later: *So too, with the Moon running through its epicycle unequally, if we now wish to prove the inequality of the appearance from unequal ones, one may observe what kind of argument it will be. For what else shall we do but give a handle to those who disparage this art?* — namely, astronomy.

III. With Copernicus, then, it was an axiom and a principle already established and assumed as certain that *the motion of the celestial bodies is equal* — that is, *per se*, and with the motion viewed from the circle's own centre. Indeed, this author was so devoted to the equality of the celestial motions, and so averse to that kind of inequality which Ptolemy had admitted in the five lesser planets as well, by introducing the equant circle into their hypothesis, that it served him as a spur to asserting the motion of the Earth. For so he himself professes in book 5, chapter 2: *The ancient mathematicians, who held the Earth immobile, imagined in Saturn, Jupiter, Mars and Venus eccentrepicycles, and in addition another eccentric with respect to which the epicycle would move equally, and the planet in the epicycle.* After this he describes their hypothesis, which we have set out with a clearer diagram in book 7, section 2, chapter 1. Then he infers against them: *But it is agreed that the equality of the epicycle ought to have been with respect to the centre of its deferent, etc. They therefore concede here too that the equality of a*

circular motion can occur about a foreign centre and not its own; and similarly that this happens even more in Mercury. But this has already been sufficiently refuted in the case of the Moon. These and similar things gave us occasion to think about the mobility of the Earth and about other ways by which the equality and the principles of the art might remain, and the account of the apparent inequality be rendered more constant. Therefore in this place likewise he assumes, among the first principles of the astronomical art, the equality of celestial motion [?] about the point that is the centre of the circle on whose circumference the motion takes place — whether of the planet or of the centre of the circle carrying the planet.

[Margin: Reinhold's opinion.]

Nor did his follower Erasmus Reinhold the Elder think otherwise, in his preface to Purbachius's *Theoricae*; since his words embrace the view of many astronomers, I shall not mind quoting them. So, after pointing out the inequalities that appear daily in the motions of the planets, he adds: *Since, then, the variety of the celestial motions and appearances, which the Greeks call* φαινόμενα*, is so manifold, the astronomers have investigated with the greatest diligence, with very long night-watches and labours, the causes of such dissimilar appearances. For the whole periods or revolutions of the orbs, which are agreed to be equable among themselves, plainly protest against and refute the notion that so great a diversity in the motions of the planets arises from some irregular motion of the celestial orbs themselves that carry the bodies of the planets, as the unskilled imagine. Therefore the astronomers hand down a learned and plain cause of this great irregularity, which is seen in the parts of the periodic motions: namely, that motions equable and uniform by their nature appear dissimilar to us, either because they take place in eccentric orbs, or because, when many simple motions are variously joined together, as it were, one single irregular motion results from them all.* This same author, further on, in the theory of the Sun and in the scholium added to Purbachius's *Theorica*, page 31, repeats things similar to those just quoted: *We said above*, he says, *that when the observations of whole revolutions are compared, reason concludes that the motions of the celestial bodies are altogether equable, constant and fixed; but if the parts of each revolution are compared with one another, a varied and manifold anomaly is detected.*

[Margin: And of Clavius.]

With much weightier words, however, and with a sterner brow, our Clavius rebukes the men of the contrary opinion (on chapter 4 of the *Sphere*, page 434), so much so that he does not hesitate to burst out into this statement: *But later men, of sounder mind, when they had begun to look at celestial things more correctly, more subtly and more scrupulously, came to the view that they pronounced it the height of madness to think that any irregularity, difformity or inequality is found in the motions of the celestial bodies; on the contrary, the highest equality, uniformity and regularity must be posited in them.* He goes on to confirm this, both *a fortiori* from some motions of sublunary things, which, though perishable and mutable, nevertheless keep a fixed law and order in their motions, and by Aristotle's arguments: namely, that in circular motion there is no beginning or end, approach to which must become faster and faster, and therefore irregular;

and that in the celestial movers there is no corruptibility or incapacity, from which, more remiss than at other times and so slower, a motion could come about; and finally, by the fixed law of periodic motion returning into itself, by force of which astronomers predict with the utmost certainty the future synods and syzygies of the planets with one another.

[Margin: Other authors for the first opinion.]

The same was the opinion of the Coimbra commentators (*De caelo* 2, chapter 6, question 2), of Suessanus (*De caelo* 2, text 40), of Philalthaeus (in the same place, text 35), of Iandunus (question 8), of Albertus de Saxonia [Albert of Saxony] (question 13), of Paulus Venetus [Paolo Veneto] (chapter 15), of Achillinus (*De orbibus* 1, doubt 3) and of Amicus (treatise 5 on *De caelo*, question 6, doubt 6, and question 5, doubt 3, article 1), though they use various distinctions; for some distinguish irregular motion from difform and unequal motion. But all of these agree that if the whole periods of one and the same planet are compared with one another — for example, the tropical solar years with one another, or the revolutions of Saturn with one another — they are entirely equal, and their whole circle is completed in an equal time. If, however, the parts of one period are compared with one another — say the northern semicircle, in which the Sun is, with the southern semicircle — they admit that the motions are indeed unequal, since they do not take place in equal times; but they refer this very inequality to appearance, owing to the position of the eyes observing these motions, or to the composition of several circles or partial orbs, each of which, taken separately, has equal motions, but which together compose a single unequal motion.

[Margin: Tycho's opinion.]

Finally, Tycho was carried off into Copernicus's opinion when he said (*Progymnasmata*, tome 1, page 11): *That all the celestial motions are regular and equable per se, and are carried round circularly by a constant law, has long since been received by all astronomers as an axiom.*

[Margin: Boulliau's opinion.]

And what may surprise you more: Ismaël Boulliau, although he contends that the motion of the planets takes place along an ellipse and not along a circle — and in this would seem about to side with the physical inequality of the motions that Kepler, the inventor of this elliptical path, had established, as we shall shortly say — has nevertheless tried to reduce this very hypothesis to equality. Accordingly, in book 1 of the *Astronomia Philolaica*, chapter 13, he sets out, among other principles, these six propositions:

1. *That the planets are moved by a single motion along a single line, as we have already shown.*
2. *That the revolutions of the planets are equal, perpetual, constant and uniform, and each like all those before and after it; and the observations of all ages confirm them to be such.*
3. *That they must therefore be regular, and composed of regular ones,*

4. *Because they are perpetual motions, they can otherwise only be circular, or along a line returning into itself.*
5. *That they are composed of circular ones, because they are completed according to the laws of circles.*
6. *That the revolutions themselves have a principle of equality, which the planet regards by its own nature.*

[Margin: Second opinion, for the inequality of the celestial motions.]

IV. The *second* opinion, however, is that the motions of the planets have a physical inequality, and not only an optical one arising from mere appearance: so that, even with respect to some proper centre of the orbit along which the planet proceeds, unequal portions of that orbit really correspond, by the nature of planetary motion, to equal times.

[Margin: Kepler.]

So, namely, Kepler, in the *Commentaries on Mars*, chapters 22, 32, 33, 34, 39, 44 and 57 taken together, and in the *Epitome of Copernican Astronomy*, book 4, part 3, and book 5, especially page 711. Indeed, earlier, Ptolemy admitted for the Moon and the five lesser planets the equant: that is, a circle with respect to whose centre the planet or the epicycle would move equally, but by which it would not be carried. Hence in the eccentric that carries the planet he admitted a motion unequal with respect to its own centre, and so, to that extent, a physical inequality. But concerning this equant, and the distinction between physical and optical inequality, I here take as already explained much that was set out in book 3, chapter 22, and book 7, section 2, chapter 1, scholium 1.

[Margin: Cabeo.]

Our Cabeo, too (on *Meteorologica* 1, text 38, question 2), teaches that the figures of the astronomical hypotheses, by which the celestial motions are reduced to equality, were devised for our use and as a foundation for geometrical calculation rather than being actually carried out in the heaven. For he says on page 221: *For just as there is in truth no mean motion, although it is necessarily supposed for calculation, so neither is it necessary that there be a motion of the eccentric or of the deferent.* And on page 222 he leans wholly towards a true and physical inequality of the motions. We, however, need a distinction in a controversy of this kind in order to set out our own opinion; and in support of it let there stand the

PRIMA CONCLVSIO.

First Conclusion.

[Margin: First conclusion, on the whole period [?] of the motions.]

Although it is probable, it is nevertheless not yet certain that the periods, or whole revolutions, of the celestial motions are equal to one another; indeed, of the Moon it is certain that they are unequal.

V. What I have said of the Moon is already known to astronomers, and indeed to those skilled in the ecclesiastical computus. For the Moon's period,

whether it is taken as the periodic month, in which it runs through the zodiac, or as the synodic month, in which it is joined to the Sun again, is sometimes greater than 30 days and sometimes less; the variety of these months becomes manifest more than once every year, and enough and more than enough has been said of it in book 4, from chapter 18 on. And so the third part of the conclusion stands proved.

[Margin: Third part of the conclusion is proved.]

[Margin: First part of the conclusion is proved.]

The first part is proved both by the authority of very many who hold this view about this equality — some of whom I have already brought forward in number 3, speaking from their own opinion and that of many others — and by reason. For an equality of this kind has in itself a beauty to be desired; and the very small difference between the periods of the other planets as observed by different astronomers is rather an indication of equality, though of an equality not yet known so perfectly that all astronomers must admit the same measure. If God had willed their periods to be unequal, and this were more fitting to the nature of sublunary things and to the perfection of the universe, they would surely at length differ from one another by some notable difference, one manifest after some centuries, as has happened in the lunar periods. Thus the motion of the solar apogee, which was unknown to Ptolemy because the interval between his own observations and Hipparchus's was small compared with the slowness of such a motion, nevertheless at length became evident after many further centuries.

[Margin: Second part of the conclusion is proved.]

The second part of the conclusion, moreover, is proved as follows. Although the Sun's period, that is, the equinoctial years, are more likely equal to one another, as I taught in book 3, chapter 30, probable reasons for an inequality of the years are nevertheless not lacking, and I adduced them there with their authors; and the widely differing length found for a year of this kind, which we displayed in the synopsis in book 3, chapter 15, number 9, also bears somewhat on the point. Once a probable inequality of the solar period is posited, the inequality of the period of the other planets becomes much more probable, since their motions are bound up with the motion of the Sun and depend on it, as is clear from book 7, section 1, chapter 7. It is made probable, besides, by the differing opinions about their periodic motions, as can be seen in the tables I set out in book 7, sections 2 and 3, where I displayed, according to the different astronomers, the various measures that must be known beforehand for the theory of the planets. Not inappropriately, therefore, Io. Antonius Delphinus, in his book *De globis ac motibus caelestibus*, page 53, infers from the uncertainty of the solar motion the uncertainty of all the celestial motions. Likewise, although the period of the fixed stars is more probably equal, according to what I have already said in book 6, chapter 17, the diversity of this period asserted by various astronomers, which I reported in the same book, chapter 16, and represented in a table, makes its inequality probable; and yet, for a particular reason, its

equality or inequality still remains uncertain. For not one of its periods has yet been completed, and so neither alternative has yet been established by observation: it requires many more than twenty thousand solar years, and yet from the beginning of the world not seven thousand years have yet elapsed.

SECVNDA CONCLVSIO.

Second Conclusion.

[Margin: Second conclusion, on the parts of the revolutions.]

Although the motions of the planets are ordered, and regularly unequal in the parts of their periods, they are nevertheless absolutely unequal — not only per accidens, owing to mere appearance or to composition from several equal motions, but per se, from the primary intention of God and from the end to which they are ordered.

VI. The former part of the conclusion, which is affirmative, is proved from the admirable symmetry of the partial motions with one another, as far as it has been possible to detect it by observation over so many centuries. For they have such fixed laws that practitioners have so far been able to reduce the motions of the planets to ephemerides and to predict them long in advance without an error that would be notable in most kinds of motions, or that could exclude astronomy from the number of the practical sciences or arts — especially in these later centuries. Nor is it the case that they lack fixed laws because small errors are still made in predicting the eclipses of the Moon and the Sun. For this art, in matters so abstruse and so far removed from our regions, it is enough if such motions and aspects of the stars as the astronomers predict from the hypotheses and astronomical tables come about as nearly as possible and for the most part — how much more if they always do so, so that for the uses of human life we can rely on predictions of this kind with the greatest security? From this, moreover, we gather that this art is far more perfect in the minds of the Intelligences that preside over such motions, and so that the rules of these motions are more certain in the nature of things than those that exist among us.

VII. The assertion of the same first part is confirmed, moreover, by the fact that not only the writers of the true religion but the heathen too rose — from the order of the celestial motions, and from the admirable harmony by which at fixed times that inequality and discord of the motions is brought back to concord — to recognising the divinity of the Godhead and the providence of God, and to extolling it with wonderful praises, though never worthy enough.

[Margin: Plato's opinion.]

Thus Plato said in the *Timaeus*: *We must assert that God begot eyes chiefly for this reason: that, beholding the circuits of mind that are carried out in the heavens, we might turn them to the use of our own mind, and recall the discursive motions of our understanding — akin to them, but in some way disturbed — to their tempered order. And when we have come to know them and, endowed with right reason according to nature, have perceived the order of each, we may imitate the revolutions of God, which proceed without any error, and compose the wandering and erratic discursive*

motions of our thought after the example of the gods. He calls the Intelligences that move the heavens gods; and their motions he calls the revolutions of God himself, inasmuch as they were first instituted by him and ordered with the highest harmony.

[Margin: Plutarch's opinion, and again Plato's.]

But Plutarch sets out Plato's view more clearly in *De placitis philosophorum*, book 1, chapter 6. There, after he had said of mortals in general, *They took their notion of God first from the beauty of the things that are seen. For nothing beautiful comes about rashly or by chance, but by the use of some fashioning art; and that the world is beautiful is evident from its form, colour and size, and from the variety of the stars that surround the world*, he added, in accordance with the mind of Plato, whom he praises there: *The things conspicuous in the heaven also complete its beauty; for the oblique circle is marked out with various images*; and, having enumerated the signs of the zodiac, he concludes: *Innumerable other things of this kind the same God scattered through the vaults of the heaven; hence, says Euripides, the starry splendour of the heaven, Chronon, finely adorned, the work of a skilled craftsman. Truly we have taken our knowledge of God chiefly from this. For with a perpetual tenor the Sun, the Moon and the other stars, having sunk beneath the earth, rise again with one colour, with equal size besides, from the same places, and at exactly the same time.* What Cicero says on this argument in book 2 *On the Nature of the Gods* is splendid, but rather long.

[Margin: Seneca's opinion.]

Let us therefore hear Seneca, who opens *De providentia*, in its very first chapter, thus: *You have asked me, Lucilius, why, if the world were governed by providence, many evils befall good men. This I should prove more conveniently in the course of a work in which I were proving that providence presides over all things and that God is concerned with us.* And soon after he lays this down beforehand as most familiar: *It is superfluous at present to show that so great a work does not stand without some guardian; that this fixed course of the stars is not the work of a chance impulse; that this unimpeded velocity proceeds by the command of an eternal law, bearing so much on land and sea, so many most brilliant lights, shining in such an arrangement; that this order is not that of wandering matter, and that things which have come together at random do not hang together with such art.*

But nothing more magnificent could be said than what is said in Psalm 18, *The heavens declare the glory of God*, etc. — where our Lorinus should be consulted first of all — and by God himself in Job 38: *Do you know the order of heaven, and will you set down its reckoning on earth?* And a little further on: *Who will declare the reckoning of the heavens, and who will make the harmony of heaven sleep?* — on which see Pineda. Not undeservedly, then, does St John Chrysostom (homily 10 *To the People*) call the heaven [Greek: βιβλίον μέγιστον καῖ ιδιῶταις, καῖ σοφοῖς (biblion megiston kai idiōtais kai sophois, "a very great book both for the unlearned and for the wise")] — a very great book open to the unlearned and the wise. And Minucius Felix says in the *Octavius*: *You see the heaven itself: now you will know how wonderful and divine is the balance of the*

supreme ruler in it. For more on this book written in golden letters, see St Basil (*Hexaemeron*, homily 11) and Nikephoros Kallistos Xanthopoulos (*Ecclesiastical History*, book 11, chapter 43).

[Margin: First argument for the second part of the conclusion.]

VIII. The latter part of the conclusion is shown thus. *First*: although inequality without any order, rule or rhythm would be a kind of imperfection, an inequality that is ordered, regular, and has rhythms and recurrences of motions at fixed times is a great perfection, and has far greater beauty than simple equality. Therefore it is this that rather befits the celestial motions; or at least this too ought to have existed in the heaven, and not equality only. So in the fixed stars, which most closely imitate the primum mobile, there would be no inequality as to the motion in longitude, nor as to latitude from the ecliptic, nor as to their distance from one another or from the centre of the world, but only some variation, though a very slow one, in the motion of declination. In the Moon, by contrast, which is nearest to the earth and closest to the sphere of mutable things, there would be the greatest inequality. In the Sun there would be only a moderate inequality — namely in the motion of longitude, of altitude and of declination, but not in the motion of latitude, since it has no latitude, nor in a motion of libration about its axis, nor that variation or second anomaly which is in the Moon and the other planets. Among these, the two nearer the fixed stars, Saturn and Jupiter, have been allotted a smaller inequality than those that are below the Sun and come [?] nearer the Moon; and of these latter, Mercury and Venus, which are bound more closely to the Sun and do not digress from it through a whole semicircle, have obtained a smaller inequality than Mars.

The antecedent is evident by induction from all the most beautiful things, whether made by nature or by art. As to nature, neither the bodies of animals nor the branches, foliage, leaves and flowers of plants preserve equality of members or parts, whether in shape, in size or in colour, but only a symmetry and agreement of unequal parts, with incredible variety. Nor are all fruits — indeed, hardly any — spherical or cubic, or aim at the mathematical beauty of some regular figure; and among things dug from the earth you would hardly find one or two that have a regular figure from nature. The tracts of the lands, the beds, as it were, of this great garden, and the tracts of the seas within them — did God from the beginning of the world confine them within the limits of a circular, quadrangular or triangular figure? Certainly not. As for artefacts, although the beauty of some requires a certain equality in figures or motions, the greater part requires inequality and disparity proportioned by fixed rules. This can be seen in architecture, in sculpture, in painting and the like; it shines out in the liberal arts, and finally, above all, in every kind of music, which bears on our subject. For if you try to reduce its motions and sounds to equality, or to derive their laws from the equality of the parts, as though they looked to that per se and primarily, you would surely rob them of all the sweetness of their harmonies and kill the soul of harmony. For what is more unpleasant, and usually borne with greater tedium, than monotony and uniformity in singing

and in modulation? Or what is more ungraceful than if dancers keeping time, or players striking the cithara, intended per se and primarily to describe a circle or some figure with equal motions?

[Margin: Second argument, from the figures of the stars, and from the asperity [?] of the Moon and the planets and the spots of the Sun.]

IX. *Second*: if equality of motions per se, and the simplest uniformity, were due to a celestial body because it is supposed to be simple, then there would also be due to it the beauty of regular figures in the arrangement of the stars, a most exactly spherical figure of the planets without any asperities, the most lustrous splendour and whiteness without any spots, and finally a perpetual light without any alternation of shadowing. But we see the opposite, all of us who look up at the heaven with eyes either naked or armed with the telescope. For the configurations of the stars are so far from regular figures that, if you except one or two triangles — and those not equilateral but isosceles — the other stars might seem to have been sown by chance and at random across the fields of the heaven, and most of them to be counted among the [Greek: σπόραδας (sporadas, "scattered")] and [Greek: ἀμόρφας (amorphas, "formless")], had it not at length become clear to those who contemplate these things deeply that this incredible variety serves agriculture, navigation, medicine and astronomy itself in a wonderful way. The asperities on the globe of the Moon; the asperities or spots on the face of the Sun, on the bands of Jupiter and on the boss of Mars; and finally the eclipses of Jupiter's satellites and the shadowings of Saturn by its attendants — already in our century were disclosed, not by a fiction of Prometheus's wand, but by the most truthful experiment of the telescope. And yet from these very things, no less than from the eclipses of the Moon and the Sun, there arises a greater elegance and beauty than if everything in the heaven had been arranged in a simple and uniform way.

[Margin: Third argument, from the end.]

X. *Third*: the end to which the celestial motions are ordered — namely, the diversity of effects in sublunary things, and the incredible variety of influences and of changes to be brought about for the sake of living things and animals, and above all for the sake of man, who was to obtain from it many more goods and much richer matter for praising and loving his Maker, who is the End of all things — requires in them some inequality, though one that is regulable and ordered. That the inequality I have described is a more apt means to this variety than mere equality is too manifest to need proof.

[Margin: The heaven and the stars were made for the sake of men.]

But that the visible heaven, and whatever stars in it shine for us, were founded for the sake of men is most true — whether the Epicureans like it or not, and certain Copernicans too, who would rather drive the Earth round the Sun than the Sun and all the stars round us, the inhabitants of a motionless Earth, as round a centre: whether they like it, I say, or not. For it is not Aristotle alone who says so — in *Physics* 2, text 23, *for we too are in a way the end of all things*, and in *Politics* 1, chapter 5, *that nature has made all things for the sake of men* —

and Cicero, *De legibus* 1. Divine Scripture too, of infallible authority, tries by this most powerful argument to deter men from offering divine worship to the stars, when it says in Deuteronomy 4: *Lest perhaps, lifting up your eyes to heaven, you see the Sun and the Moon and all the stars of heaven, and, deceived by error, adore and worship the things that the Lord your God created for the service of all the nations that are under heaven.* For what is more foolish than that man, to whom the supreme Lord granted a certain useful dominion over visible creatures, should offer worship and adoration to his own servants and handmaids? For God, as Genesis 1 has it, placed the stars in the firmament of heaven not to shine for one another or for the heaven, but *to shine upon the earth*. On this, rightly, Lippomanus in the *Catena*: *But if they were placed by God for this purpose, to illuminate the earth, then not to rule over men; for it is the Lord who created them for the use of men.*

The sacred interpreters may be consulted on that passage of Psalm 8 where David, having said *For I shall see your heavens, the works of your fingers, the Moon and the stars which you have founded*, at once, astonished that God had subjected these too to man, exclaimed: *What is man, that you are mindful of him, or the son of man, that you visit him?* etc., and *You have set him over the works of your hands.* These words are to be understood chiefly of Christ, at least in the mystical sense — for it belongs to him more properly to be the son of man, that is, of the Virgin Mary alone, since the others are sons either of no human being, like Adam and Eve, or of two — and St Paul understood them so; yet not a few Fathers teach that literally they can be taken of any man whatever, as may be seen in Ioannes Lorinus on that psalm, and some hold that the former part, *What is man* etc., applies to every man, and the latter, *or the son of man*, peculiarly to Christ. And certainly that saying of the Apostle in 1 Corinthians 3 applies to men: *All things are yours, whether the world, or life, or death, or things present, or things to come.*

[Margin: St Chrysostom's opinion.]

That those who deny that the stars were made for us favour the error of the Gentiles, I gather from St John Chrysostom, who says in homily 6 on Genesis: *Let us teach with all gentleness those who are taken up beforehand by the Gentile error, so that they do not confound the order, nor, abandoning the Creator, adore the creatures, which were made for our salvation and benefit. And if what you teach displeases the Gentiles, cry out nevertheless with a clear voice that all these things were made for the sake of the human race. For the Maker, wholly sufficient to himself, had no need of any of them; but he produced all these things to show his indulgence and kindness towards us — showing with how great honour he regards the human race — and so that, led by the hand by these things, we might ascend to the adoration that befits him.* There this golden Doctor was explaining the work of the fourth day and the formation of the luminaries and the stars.

[Margin: Lactantius's opinion.]

Lactantius too teaches, in his book *De ira Dei*, chapters 13 and 14, that the heaven was made for us, as St Nyssenus also does in his book *De opificio hominis*, chapters 1 and 2; and in book 7 of the *Divine Institutes*, chapters 3 and 4, he

inveighs not only against the Epicureans, who deny that the world was made for us, but also against the Platonists, who did assert the providence of God but did not expressly teach that the world was made for us — which, however, the Stoics did teach. *Plato, therefore*, he says, *and those who held the same view, ought to have taught and explained what the cause, what the reason was for fabricating so great a work: why, or for whose sake, he made it. The Stoics likewise say that the world was made for the sake of men.* And a little later, against Plato, who asserted that the world would be eternal, he argues in this way: *If the world was made for the sake of men, and was made such as to be eternal, why then are they themselves, for whose sake it was made, not everlasting? If those for whom it was made are mortal, then it too is mortal and dissoluble; for it is not of more worth than those for whose sake it was made.* And again: *But whoever denies that it was made for the sake of men holds to no reason at all. For if he says that the maker himself contrived such great works for his own sake, why then were we born? Why do we enjoy the world itself? Why do we intercept advantages belonging to another?* etc. *God, doubtless, wished to be seen, and to fashion figurines, as it were, of his various images with which to delight himself; and nevertheless, if this were so, he would have care for living beings, and above all for man, to whose rule he subjected all things.* But what the same Lactantius says in chapter 4 — *The world, therefore, was made by God, certainly not for his own sake; for he needs neither the heat nor the light of the Sun*, etc., *and God himself does not use all these things that are in the heaven and that are generated* — must be corrected; for *the Lord has made all things for himself*, as is said in Proverbs 16.

Rightly, therefore, Froidmont teaches in his *Vesta*, from Tertullian, *that both the stars and the elements serve man*; and Io. Bapt. Morinus [Jean-Baptiste Morin], against Lansbergen, observes that it befitted God to have regard in these motions to the utility of men, and not only to the ease or economy of nature; and Father Nicolaus Zucchius [Niccolò Zucchi], in his *Nova de machinis philosophia*, part 5, section 11, is indignant with those who strive to suppress this truth, though Scripture and the arrangement of the whole universe resist them. Nor should it seem too much to anyone that bodies so vast and sublime were made for men. For since they were made so that a contemplative creature might recognise and adore the Creator from them, and an angel, being itself without senses, would not need the beauty of the sensible world for that purpose, it remains that all these sensible things were made for men alone, and man himself and all things for God.

[Margin: Andreas Hierosolymitanus.]

Pointedly, therefore, Andreas Hierosolymitanus said in his sermon on the Angelic Salutation that man is the one *for whose sake God* [Greek: ουρα[ν?]οὺς ἐκαμαίρωσαι (the fifth letter of the first word faintly printed, probably ν; the Latin that follows renders the sense "founded the heaven")] etc., that is, *founded the heaven, made firm the earth, spread out the air, widened the seas, and in short made the whole mass and fabric that lies before our eyes to be looked up to*. And so elsewhere he calls man [Greek: μέγα τῆς ἐργασίας κατόρθωμα (mega tēs

ergasias katorthōma, "a great achievement of the work")] — that is, a huge specimen of the divine operation.

[Margin: St Augustine.]

And St Augustine (sermon 225, *De tempore*) says of him: *Man, the dear and beloved possession of God; man, for whose sake the heaven was made firm.* Nor should you say that it seems incongruous that this greatest world and the immense mass of the heavens were made for a manikin three cubits tall. For although man was called by the heathen philosophers [Greek: μικρὸς κόσμος (mikros kosmos, "little world")], and is smaller than the heaven in bulk, he is nevertheless more august and greater in the perfection of his nature and in his rational nobility.

[Margin: Arnobius.]

Arnobius touched on this, indeed, in book 2 *Against the Gentiles*, in these words: *This is that precious man, endowed with most august reasons, who is called the lesser world, and fashioned wholly in the form of a likeness.*

[Margin: Hermias.]

Indeed, in Protagoras's opinion (Hermias, *Mockery of the Gentiles*), man was called [Greek: ὅρος καὶ κρίσις τῶν [recte: τῶν] πραγμάτων (horos kai krisis tōn pragmatōn, "the boundary and judgement of things")] — *the boundary, judgement and norm of things*.

[Margin: St Gregory Nazianzen.]

But St Gregory Nazianzen, in oration 38, expressly denied that man is a [Greek: μικρόκοσμον (mikrokosmon, "microcosm")], *a small world*, and rather called him [Greek: μέγαν κόσμον ἐν μικρῷ (megan kosmon en mikrō, "a great world in a small one")], *a great world in a small one*. For the rest, to whom should it seem wonderful or incredible that the heaven and the stars were made for the sake of men, if the Son of God — as the Church professes in the Creed, and, bowed down under the weight of the immense benefit, sings: *Who for us men, and for our salvation*, etc.; and in that sweetest hymn: *Given to us, born for us*?

[Margin: Synesius.]

Aptly, therefore, Synesius (letter 57) on man: [Greek: τίμιον ζῶον ὁ ἄνθρωπος (timion zōon ho anthrōpos, "man is a precious animal")], etc. — *man is a precious animal, if for his sake Christ was raised upon the cross*.

[Margin: St Ambrose.]

And St Ambrose, on Psalm 118, calls him *the precious work of God*; and in his book *De bono mortis*: *The whole world is small against the loss of a single soul.* Finally, St Gregory of Nyssa (homily 4 on Ecclesiastes) affirms that not even the whole world is [Greek: ἄξιον τῆς ψυχῆς ἀντάλλαγμα (axion tēs psychēs antallagma, "a worthy exchange for the soul")], *a worthy price for the soul*.

Let Lucretius, then, be gone — he of the herd of Epicurus, more used to grunting than to singing — when he dares to say:

To say, further, that for the sake of men they willed to prepare the glorious nature of the world, etc. *is folly: for what is it to the immortal and blessed that they should set about doing anything for our sake?*

I grant, indeed, that there will be some who think I am now wandering off the subject, and playing the preacher or the churchman rather than the astronomer. But from what has been indicated they ought to consider that these weapons of ours are aimed at two kinds of enemy. The first consists of those who attribute an annual motion to the Earth and will not have it be the centre of the celestial motions; nor will they have the stars revolved for the sake of the living things placed on it — not even for the sake of man — in such a way that the Earth too, and man with it as the inhabitant of a planet, is not revolved around some other, more principal body in the world. For this reason they make light of this doctrine that the Heaven and the World were made for man. The second kind consists of those who are too much attached to the equality of the motions: seeing that the motions are unequal with respect to the Earth, or to the centre of the world from which we observe them, they deny that these motions are ordered per se to this centre, or exist for our sake.

[Margin: Summary of the third argument, and its twofold force.]

Against these, then, we hurl this twin argument — set out rather loosely before, but now gathered into a few words, as though by a throwing-thong: *The motion of the heavens and the stars is unequal with respect to the men who observe it; but the motion of the stars per se — that is, from its primary end and from God's principal institution — is unequal; therefore it is unequal per se, and not merely per accidens.* And again: *The motion of the heavens and the stars, in relation to the variety of effects which sublunary things were to enjoy for the sake of man, and man himself above all, had to be unequal; but this same motion is ordered per se to the variety of those effects, and above all to the benefit of man; therefore this motion had per se to be unequal.*

[Margin: 4th argument, from the relation of the parts to the whole.]

XI. *Fourthly.* It is admitted among the astronomers who champion the equality of the motions that if the whole compound motion of the planets is considered, it is unequal, since it is carried out through different circles described from different centres; but that if the motions of the individual circles are considered separately and one by one — for instance, the motion of the centre of the epicycle on the eccentric, and the motion of the planet's body on the epicycle — they are simple and equal about their own centres. Now I argue thus. The motion of the parts is not for the sake of the parts themselves, nor is it per se when compared with the whole; rather, it is per se for the sake of the whole. Or at any rate, when the parts are compared with the whole, what holds per se is rather the whole itself, as the end and as something complete. But the whole motion arising from these partial motions is unequal, even granting that the partial motions are equal. Therefore the motion of the planets is unequal per se.

[Margin: 5th argument.]

XII. *Fifthly.* If the motion of the stars were equal per se — that is, considered in relation to its own centre — it would have had to be ordered by God to that centre as to some good, something more excellent than the moving body itself. For if you say that equality belongs to them for their own sake and not for the sake of the centre, that is the very point in dispute, and it must not be assumed as granted. Indeed, the bodies themselves are of themselves indifferent to motion about this or any other point of the universe. Therefore, if in their motion they depend per se on a single point, the centre of their circle, they certainly acquire perfection from it, either as from an end or as from an efficient cause that exerts influence. But neither the centre of the eccentric nor the centre of the epicycle has any dignity in the universe, or any power of exerting influence on the stars — unless someone invents it gratuitously and rashly. They are unstable points in the universe, of no magnitude, not to say of no excellence. Inappropriately, then, is the quality [?] of the motion of the heavens judged by its relation to such points; and so equality per se, founded on them, has an unstable foundation of no weight.

[Margin: 6th argument, from the position of the spectators and from sense.]

XIII. *Sixthly.* If the apparent, or optical, inequality is per accidens because our eye is now outside the centre of the circle along which the planet moves, and no eye is at the centre of the eccentric or of the epicycle from which it could see the motion as it is per se and as it ought to be seen, then that perfection lacks a spectator, and only the imperfection — that is, what is per accidens — has had a spectator. This seems to detract from divine omnipotence. And if you say that God gave man not only the eyes of the body but also those of the mind, so that by reason he might infer from the inequality of the apparent motion the theory of a motion equal per se, against this stands the fact that, in this judgement, possession lies on the side of the senses. Unless the intellect is evidently or certainly compelled from some other source to correct the judgement it formed about these motions in reliance on the senses, it ought to pronounce for the senses, and to judge these motions to be such as, by the constant experience of observations through all ages, they are established to have been found — namely, unequal. Granted that, for ease of calculation and because of our weakness, we imagine mean and equal motions, and use perfect circles to set them out — that is, circular motions made equally about their own centres. But this equality, or rather this fiction of equality, is per accidens in this art; the inequality, therefore, is per se.

[Margin: 7th argument, from rectilinear motion.]

XIV. *Seventhly.* Some celestial motions take place along straight lines, or chords of circles, according to Copernicus, Maginus, Longomontanus and Lansbergen — certain librations, for example. And yet, to preserve equality, they take their law from a circle, and those motions are imagined to be made in a circle, although in fact they are not. Therefore, if one considers the path along which they are really accomplished, those motions are unequal per se. The same argument holds for motion along an elliptical circumference, according

to Kepler and Boulliau. For in reality, as these two astronomers hold, the planets are carried unequally along the circumference of an ellipse — granted that, as Boulliau adds, circles can be drawn through any two extremities of the ordinates in the ellipse, and some rule of equality taken from them; for the planet does not travel along those circles. Moreover, it is one thing to be moved equally per se, which we deny of the stars, and another to take from an extraneous circle laws — not of equality, but of some regular increment or decrement of motion — which could be granted: as if a moving body were carried along a straight line, but with the variation that the sines, or the secants or tangents, require, taken for an equal number of degrees in equal time. But from this it would rather follow that the inequality itself is intended per se, since to preserve it — though by some rule — a fictitious equal motion through a circle is taken from outside. In the same way, if an instrument were made for describing an ellipse or a parabola, which, by some part of itself being carried round in a circle, were fitted to describe an ellipse or a parabola, the ellipse and the parabola would certainly be intended per se, as the end, and the motion in a circle as the means. So too, even if the choirmaster, or chief musician, measures out the beats for the singers in equal time by equal raisings and lowerings of the hand, what he intends per se is that they, following the musical notes, should raise and relax their voices, lift or lower them, quicken or slow; and he looks per se to the inequality of the harmony, not to the equality of the beat.

[Margin: 8th argument, from the motion of the fixed stars.]

XV. *Eighthly.* The motion of the fixed stars in declination, and the variation of their right ascensions, is unequal, and does not vary equally in equal time, as is known from the problems of the primum mobile. Yet it is such in relation to its own centre, and follows necessarily from the equal motion in longitude; nor can it be said with any foundation that this motion is intended per accidens and the motion in longitude per se. Just as this motion, then, is unequal per se, so there can be others in the heaven.

[Margin: 9th argument, from reconciling the motion of the planets with the primum mobile.]

XVI. *Ninthly.* There is no better or simpler way of reconciling the proper motion of the planets with the motion of the primum mobile than by spirals and helices, as we showed in chapter 3. But these are not ordered to a single centre: they loosen and tighten like a screw, and rise and fall in various ways. Therefore that equality taken from perfect circles is not intended per se by Nature or by God.

[Margin: An objection refuted.]

XVII. Further, the opponents assert that it is an axiom long received in the schools of physics and astronomy that a simple body — and every celestial body is of that kind — must also have a simple, that is, an equal, motion. The reply would be that this is true of the motion of the primum mobile, or indeed of the motion of the secondary movables, but with equality taken as it is opposed to irregularity and randomness, that is, to disorder of motions. Otherwise it is

denied to be an axiom; or at least it is granted, but of a body that is simple not only in its being but also in its character as a cause, or in its effects — and in neither way are the heaven or the stars simple. Moreover, Aristotle's arguments are only topical, and do not contain the adequate cause of inequality in motion; for that inequality can arise from a source other than the end and terminus in which the moving body desires to rest, or than from the impotence of the mover, or from the resistance of the subject that is moved, as is evident.

CAPVT V.

Chapter 5.

Whether the Intelligences that move the heaven and the stars intend per se the description of some geometrical figure, or depend on it as on a rule; or whether, by the power of logistic alone, they accomplish the numbers of the motions; and whether men should attempt the same in setting out these motions.

[Margin: The opinion of Petrus Ramus on astronomical hypotheses.]

I. The occasion for this controversy was given us by Petrus Ramus [Pierre de La Ramée], whose opinion is best heard from Tycho, in his letter to Rothmann [Christoph Rothmann] of 1587 January 20, where he writes and judges as follows: *That the most celebrated philosopher of our age, Petrus Ramus, thought that astronomy could be established without hypotheses, by logical reasonings, has no foundation. He did indeed put this opinion to me sixteen years ago, when we were together at Augsburg, and at the same time he urged me that, once I had reduced the course of the stars to exact order by means of hypotheses, I should aim to attempt the same without them. That this could be done, he added, rested on this reason: that he had read that the Egyptians once had a very easy knowledge of astrology; and since the method of hypotheses seems difficult and intricate, they must have known the courses of the stars by some other, shorter and plainer way, and so without any hypotheses.*

[Margin: Tycho's verdict on P. Ramus.]

So Tycho writes on page 60, and he appends his judgement and verdict in these words: *But I resisted him, showing that without hypotheses the celestial phenomena cannot be reduced to certain knowledge, nor be excused [?] so that they may be understood; and that that Egyptian ease existed only in the planetary equatoria, by which they freed themselves from tedious computation when the convenient method of ephemerides was not yet in use. But since this man, though otherwise endowed with a penetrating intellect and a lover of truth if anyone ever was, seemed to me not to have thoroughly seen into the inner recesses of this art, and not to have noticed the variation in the motion of the stars, which by no means recurs at fixed times of the year, I neither could nor would obtain anything from him on this point. He still has a great many followers, who hope that the same can be done; but they neither understand the matter itself nor will ever bring it to effect. For since all things consist in numbers, weights and measure, without these nothing even in the invisible world can be explained. Hypotheses, moreover, show nothing other than the measure of the apparent motion through a circle and other figures, which arithmetic resolves into*

numbers. Anyone who wants to comprehend the motions of the stars without these must invoke Fortune, as the saying goes, and imagine a supramundane reason, beyond human understanding, wholly incorporeal and more than angelic.

[Margin: The opinion of Patrizi, and Kepler's verdict.]

So far Tycho against Petrus Ramus. And Kepler says much the same against Franciscus Patritius [Francesco Patrizi], in the *Commentaries on Mars*, chapter 1, where, having pointed to the ancients' observation of a double motion in the heaven, he adds: *This first sketch of astronomy — which consists in no explanation of causes but only in the very slow experience of the eyes, and which can neither be explained by diagrams or numbers nor drawn forth into future times, since it perpetually disagrees with itself, so that no spiral equals another in its duration of time, and none passes into its neighbour by a bend of the same size — this, I say, some people nevertheless try to restore today, trampling on two thousand years of labour, diligence, learning and knowledge, and thrusting admiration of themselves on the common people — an effort not in vain among the unskilled. The more skilled judge them, with full right, to be talking nonsense, or, if they wish to be heard as philosophers, like that Patrizi, to be mad with reason.*

Add to this that God is said (Wisdom 11) to have disposed all things in measure and in number and weight, and by Plato in the *Timaeus* to do geometry; and finally, that if it can be done that the phenomena of the celestial motions are represented by some figure having the beauty [pnlchritudinem] of a geometrical figure, this is better than to set out those motions without this form.

[Margin: The defence of Ramus and Patrizi.]

II. Yet reasons not to be despised present themselves in favour of the opinion of Ramus and Patrizi. *First*: of all the many geometrical figures that astronomers have so far tried to fit to the celestial motions — whatever they may boast, Lansbergen especially — none yet fully satisfies all the properly observed phenomena of a single planet without some discrepancies coming to light every year, both in eclipses and in the other vicissitudes of such motions; and not a few attribute this to the hypotheses being fabricated rather than to a defect in the observations. Now what has not been achieved through these hypotheses hardly seems achievable hereafter through others, since every combination of eccentrics, epicycles and concentrics, and every form of hypothesis through circles or ellipses, seems to have been tried, as is clear from what was said in Book 7, Sections 2 and 3. And the multiplication of small circles is liable to more errors the more differences of motion it has been compounded from.

[Margin: 2nd reason.]

Secondly: that necessity of a geometrical hypothesis seems to have arisen from our weakness or our habit rather than from the nature of such motions. For since we have been versed in the mathematical dust from our youth, and can hardly do without the apparatus of geometrical demonstrations — or can only with difficulty imagine the causes and rules of the celestial motions without it — we seem to need these in order to understand and to teach their theory. This is especially so because we do not have every one of the observations

that would show us one whole period, explored day by day part by part, and display its constant ratio. Therefore we are compelled, in a way, to hunt out the remaining equations of the mean motions — which we ourselves devised for easier use in calculation — from the necessity of some geometrical figure by whose laws the planets are bound. And this, evidently, is why we never attain the subtlety of astronomical truth: we hunt the planets' route along a path that we ourselves have devised. But if we had sufficient observations, taken on every single day, we could perhaps give an account of these motions without the laws of geometry, through purely logistic laws — that is, through very recondite ratios and proportions of numbers.

[Margin: 3rd reason.]

Thirdly: the motions of the stars are most probably carried out along spirals, as we said in chapter 3, and these are unequal per se, as we showed in chapter 4. But these two conditions do not seem to fit easily within the bounds of any geometrical figure; rather, they indicate that the planets' motions are freed from those bounds and bound by other laws, outside the jurisdiction of geometry.

[Margin: 4th reason.]

Fourthly: it befits the dignity of the Intelligences that move the heavens and the stars that in these motions they should follow the ideas of numbers, which abstract from sensible and imaginable matter, rather than those of continuous quantity, which does not abstract from it; and that they should not need, to direct those motions, the sight of circles or ellipses or similar figures. And if perhaps they trace any figures in the heaven by those motions, these are something posterior and a consequent effect, but not an exemplary cause or idea that they need. In the same way, no figures of the various motions are set before singers, or cithara-players, or those who dance in time, for them to imitate — figures which they do trace with tongue, hand or feet, like a passing track in the air.

[Margin: 5th reason.]

Fifthly: the proportions of the motions by which various pendulums are swung to and fro, together with their intervals, follow the ratio of evenly odd [?] numbers, so that the heights of any two pendulums are to each other as the squares of the times; and the increments of speed in the natural motion of heavy bodies keep a similar proportion, as we showed in Book 2, chapters 20 and 21; and in these the law of no figure is attended to. In the same way, it seems probable that there are similar, or more sublime, ratios in the minds of the Intelligences, by which they infallibly lead the stars round and present them in their places at the appointed time, without the aid of any figure.

[Margin: Conclusion.]

III. Let us conclude, then, that geometrical figures are indeed to be used, as long as nothing better or more certain presents itself; but that they are not to be passed off as the true causes of the anomaly of the celestial motions, nor that one should pass from the name of a hypothesis to the real neces- sity of such a figure. Meanwhile, however, let us conclude that what was said under

number 2 is probable: namely, that the Intelligences use purely logistic ratios for the harmony of these motions, without the sight of a figure directing them, or of one set before them, as their primary intention, to imitate. Yet it is not improbable that they follow those logistic ratios in the archetype of their mind in such a way that they also wish at the same time to represent the beauty of some geometrical figure, joined with the niceties of arithmetic — but of a figure to which that spiral motion, made as it were like a screw, can be fitted. However that may be, whatever geometry and harmony may be imagined in this must both agree with the phenomena and be taken rather from the end that divine Providence set before itself in motions of this kind. Therefore, just as it would be the mark of an unskilled man to hold that God practised geometry in the human body — geometry taken properly and not metaphorically — and bound the motion of the heart, of the arteries and of the animal spirits to some regular figure, or assigned to the heart the figure of a perfect pyramid, to the brain a spherical one, to the liver a cubic one and to the kidneys a cylindrical one; so, if figures of this kind conflicted with the end of the various effects to which these motions are ordered, they would certainly have to be banished from the heaven to the mathematical dust. But it is not yet established that they evidently conflict with this end.

CAPVT VI.

Chapter 6.

Whether the proportions of the celestial motions are knowable by us in this life, and expressible; and whether they are all rational, or rather some irrational; where also of the revolutions of all of them into the same.

I. What Plato thought on this matter will become clear from his *Epinomis*. There he calls those who were occupied with mere observations of risings and settings, and with the prognostics to be drawn from them, [Greek: τοὺς ἀστρονομοῦντας (tous astronomountas, "those who practise star-observing")]; but he calls [Greek: ἀστρονόμους (astronomous, "astronomers")] those who search into the celestial motions themselves.

[Margin: Plato's opinion.]

And he says: *You do not know astronomy. For he who is truly an astronomer must be most wise — I do not mean the one who practises astronomy after the manner of Hesiod and all those like him, as one who contemplates the risings and settings of the stars, but the one who studies the seven periods of the eight periods, each of which runs through the same circle in such a way that all nature is scarcely, scarcely equal to contemplating them, unless it shares in that wonderful nature.* I believe, however, that by "the seven periods of the eight periods" — for so the Greek text has it, [Greek: τῶν ὀκτὼ περιόδων τὰς ἑπτὰ περιόδους (tōn oktō periodōn tas epta periodous, "of the eight periods, the seven periods"; the breathing on ἑπτὰ is printed smooth)] — he means not the simple revolutions of the fixed stars and of the planets separately, but the revolutions of all of these together to the same

point, which they usually call the Platonic year. This accords with that passage of Cicero in the *Dream of Scipio*: *But when all the stars have returned to the point from which they once set out, and have brought back the same configuration of the whole heaven over long intervals, then that can truly be called the turning year; and I hardly dare say how many generations of men are contained in it.* Of this year, then, both the proportions and the commensurations of the celestial periods no one can perfectly attain, in Plato's opinion, unless he has been allotted a heavenly and admirable intellect. Aristotle, however (*De partibus animalium* 1, chapter 5), notwithstanding this difficulty, which he admits is met with, says that even a modest knowledge of these things is more delightful than the knowledge of certain others.

[Margin: Delfino's opinion.]

Indeed, Io. Antonius Delphinus, in his book *De caelestibus globis et motibus*, chapter 23, contends that no one, while he remains shut in the prison-house of this mortality, can naturally have indubitable knowledge of the proportions and measures that are precisely inherent in the celestial motions. For those proportions consist in an indivisible, and even the least difference alters them; and because of the distance of the stars, differences of this kind remain insensible within the life of one man, but afterwards, with the passing of the ages, become sensible.

[Margin: Clavius's opinion.]

Our own Clavius [Christoph Clavius], too, toward the end of his *Commentary on the Sphere of Sacrobosco*, speaking of Copernicus's attempt to correct the celestial motions, concludes thus (p. 452): *It is very difficult to define the periods of the motions so that they do not deviate from the truth over many centuries of years, since no mortal has ever been able to determine the period of a single planet so exactly that some small fractions are not left over or lacking, which over a great interval of years introduce a notable error. So that it is truly wonderful that God, Best and Greatest, willed to obstruct the motions of the planets with such difficulties that no man can attain them perfectly, but always finds something to admire in so great an artifice of such noble bodies, and in so great a harmony and concord of their motions — celebrating their founder and mover with perpetual praises. So that it seems to have been written by Ecclesiastes, chapter 3, chiefly on account of the constitution of the heavens and their motions — in which there always seems to remain something to be investigated with the greatest diligence by the most skilful searchers of celestial things: And he delivered the world to their disputation. That is, lest, if men should at some time perfectly understand the number, order, constitution and motion of the heavens, they should cease to investigate and admire the works of God, and their minds, the reason for exercising them taken away, should grow torpid through idleness.*

[Margin: Job 38.]

II. But we learned long ago, from the divine writings and the sacred writers, how arduous this astronomical business is. For what else does that thunder of the divine voice mean, speaking to Job out of the whirlwind: *Do you know the order of the heaven, and will you set down its plan on earth?* And again in the

same chapter 38: *Who will declare the plan of the heavens, and who will make the harmony of heaven sleep?* That is, if I am not mistaken: who will describe and explain the motions of the heavens so perfectly that men, now unconcerned about their course, would cease from observing the motions of the stars in future, and so sleep? For just as the heavens are said to praise the Lord because they rouse men to the praises of the Lord and are an object that moves them to praise him, so they would also be said to sleep if they were so well known that they now invited men to sleep.

[Margin: Solomon's knowledge of these things, infused.]

And although Solomon proclaimed that the wisdom of these things had been infused into him by God, saying (Wisdom 7): *For he himself gave me true knowledge of the things that are, that I might know the disposition of the world and the virtues of the elements, the beginning and the end and the middle of times, the alterations of the vicissitudes and the changes of the times, the courses of the year and the dispositions of the stars*; yet the same writer (Wisdom 9), considering the purely natural powers of human ingenuity, declares: *And hardly do we judge the things that are on earth, and the things that are before us we find with labour; but the things that are in heaven, who will search out?* And indeed the Fathers press the judicial astrologers from this: that it is impossible to know the course and aspect of the stars exactly — above all Saints Basil (homily 6 on the *Hexaemeron*), Ambrose (*Hexaemeron* 4, chapter 4), Augustine (*City of God* 5, chapter 3) and Gregory (homily 10 on the Gospels). Add to these Origen, in Eusebius, *Praeparatio Evangelica* 6, chapter 9;

[Margin: Philo's opinion.]

and Philo, in his book *On Dreams*, who, after recounting various opinions about the stars, concludes: *What is reported of them and of the heavens is uncertain and incomprehensible, and rests on probable conjectures rather than on certain and true reasons, so that one might lawfully swear that no mortal can ever rightly perceive any of these things.*

[Margin: Martinengo's opinion.]

III. Whether the periods of the celestial motions are commensurable with one another and consist of rational proportions, or rather of irrational ones, astronomy has not yet advanced far enough for this controversy to be settled with certainty, and it will be enough to have indicated the opinions. For, as Ascanius Martinengus says in the *Glossa magna* on Genesis, p. 1045: *Certain very learned mathematicians have judged, on the best reasons, that the revolutions of the heaven are incommensurable with one another, and that for this reason the same face of the heaven and the same position of the stars can never return; and they strive to confirm this with no weak reasons. Others have held that the configurations of the stars return to the same only after thirty-six thousand years, or, according to others, forty-nine thousand years, in which the revolution of the supreme and slowest sphere will be completed.*

[Margin: Io. Antonius Delphinus.]

So too Io. Antonius Delphinus, in his book *De globis ac motibus caelestibus*, chapters 24 and 25, defends both sides as a problem, and adds that it is not sufficiently proved from this that these motions are asymmetrical — from the fact, that is, that astronomers have so far disagreed among themselves about the measure of the solar year and of lunations. This, he says, happened because of the shortness of life and because the restitutions [apocatastases] of these periods went unobserved, or were badly observed; and for that reason the astronomical tables must be restored every two hundredth year, so that the fault of the old observations may be corrected. And certainly, if the commensurability of any motions at all ought to be established, it would surely be that of the Sun and the Moon with each other, because the observations of them are frequent and more evident. And yet, as we showed in Book 4, chapter 19, no lunisolar cycles have so far been found at whose completion the luminaries are restored to the same point in which they were once conjoined together. That very period of 3400 Julian years which Franciscus Vieta [François Viète], in his *Calendar*, proposition 31, put forward as the most suitable of all for this purpose, is not such a period, if we believe Kepler in the *Rudolphine Tables*, precept 135: for it falls short of an exact restitution by 1′ 19″. Nor can it be such a period, says Clavius in his *Calendar*, chapter 24, unless the synodic month is $29^{d}\ 12^{h}\ 44^{m}\ 3^{s}\ 10‴\ 43⁗$ — and Vieta has not yet proved that it is so much.

[Margin: Boulliau's opinion.]

Indeed Boulliau, in Book 2 of the *Astronomia Philolaica*, chapter 3, after saying, *But that measure is false, for the motion of the Sun does not depend on the lunar one. Nor, certainly, did the ancients succeed any better in making the annual motion of the Sun commensurable with the lunar synods*, says a little later: *For who has so far asserted and proved that the annual motion of the Sun is commensurable with the lunar cycles?* To this Amicus (*De caelo*, treatise 5, question 6, doubt 10) teaches that these proportions can remain unknown, but that even if they are irrational, this is no imperfection in the heaven, because they are commensurate with the end appointed by God.

[Margin: Kepler's opinion.]

Kepler, however, contemplated these matters with a deeper effort of mind. In the *Epitome of Copernican Astronomy*, Book 4, p. 512, he drew this distinction: *The tempering of the extreme motions, the slowest and the fastest, in any one planet is most exquisitely harmonic, and is the work of the supreme and adorable Creating Mind. But the lengths of the periodic times, if they were the work of a mind, would have something of beauty, of the kind that effable proportions have — double, triple and the like. As it is, the proportions of the periodic times are ineffable (commonly called irrational), and so share in infinity, in which there is no mental beauty, because there is no limit.* He confirms, moreover, that these times cannot be the work of a mind, in these words: *Secondly, these times cannot be the work of a mind (I do not speak of the Creator, but of the nature of the mover), because the times of one period are gathered from unequal stays in different parts of the circle; and those unequal stays, as will be said below, arise from material necessity, and as it were*

from the principle of the steelyard. So he writes, wholly intent on showing that the planets are moved not by Intelligences but by the Sun, according to the principles of the balance and the lever and by magnetic tractions, and the Sun in turn by a certain material soul. In the *Mysterium Cosmographicum*, chapter 23, however, investigating the end of the astronomical world and the Platonic year, he concludes in these very words: *I shall prove from a single postulate that no end can be set to motion with reason, and that there will be no Platonic year. For let it be granted that the eccentricity is in a rational proportion to the orb: then the radii of the orbs will be irrational to one another, because they stand to one another as the radii inscribed in and circumscribed about the bodies, and these are irrational, since they follow from the ratio of the subtense in the square and of the section in extreme and mean ratio, which are the two examples of irrationals in geometry. But the motions are in proportion to the radii; therefore the motions are irrational to one another, and so they will never return to the same beginning, even if they lasted for infinite ages: because never, not even in an infinite division of time, would there occur a common measure which, repeated often enough, could be set up as the one terminus of all the motions and the goal of the Platonic year.*

[Margin: The Platonic year impossible, for Kepler.]

This established, he exclaims with Pliny the Elder (Book 2, chapter 1): *The world is sacred, immeasurable, whole in the whole, nay rather itself the whole, finite and like the infinite*; and with Copernicus (Book 1, chapter 10): *So great, truly, is this divine work of the Best and Greatest.*

[Margin: Criticism of Kepler's opinion.]

IV. But Kepler's argument already mentioned, drawn from the comparison of the orbs and of the eccentricities, does hold in a hypothesis that employs the figure of an eccentric orb, or in one equivalent to it as far as geometry is concerned; but not in every hypothesis that is equivalent only as far as the numbers are concerned — for example, in a spiral motion made along helices, or if Angels move the heaven and the planets using purely logistic rules, without regard to circles, ellipses or similar figures. Nor is it evident that proportions which are ineffable to us, or at any rate are so because they tend to infinity, are devoid of all beauty, since the divine Immensity and Eternity possess every perfection of the infinite and yet do not lack their own beauty. Just so, it is not evident either that it is not more beautiful for the celestial motions to have proportions of both kinds. Finally, I do not approve of his making God the author of the effable proportions while denying that He is the author of the ineffable ones.

CAPVT VII.

Chapter 7.

Of sound and concord, or of the harmony of the celestial motions.

I. Since this harmony arises not only from the celestial motions but also from the intervals of the distances and from other proportions, and does not behave

in the same way in every system, it has seemed best to defer this controversy to the last section of this book, in which the harmonic and geometric system will be treated, so that with that last sound, as it were, the ears of the learned reader may be refreshed.

SECTIO TERTIA DE SYSTEMATE MVNDI CIRCA TERRAM IMMOBILEM.

Section 3. On the system of the world about an immobile Earth.

Authores Præcipui qui de Syſtematibus Mundi tractant.

The principal authors who treat of the systems of the world.

Ptolemy, *Almagest* Book 9, chapter 9, and there Theon and Regiomontanus; Macrobius, Book 1 on the *Dream of Scipio*, chapters 19 and 21; Copernicus, Book 1, chapter 10; Fracastorius [Girolamo Fracastoro] in the *Homocentrica*, sections 1 and 3, chapter 25; Io. Baptista Amicus [Giovanni Battista Amico] in his short work *De motibus caelestium corporum*; Io. Antonius Delphinus [Giovanni Antonio Delfino] in his book *De globis ac motibus caelestibus*; Valentinus Naiboda [Valentin Naibod], Book 1 of the *Astronomicae institutiones*, chapters 10 and 16; Clavius, Book 1 on the *Sphere*, from p. 64; Franciscus Barocius [Francesco Barozzi], *Cosmographia* Book 1, chapter 2; Ascanius Martinengus, *Glossa magna* on Genesis, p. 968; Galileo, in the *Dialogues on the Two Systems of the World*; Longomontanus, *Astronomia Danica*, Book 1 of the *Theorica*, chapter 1; Sheinerus [Christoph Scheiner] in the *Disquisitiones mathematicae*, from number 13; Andreas Argolus [Andrea Argoli] in the *Pandosion sphaericum*, chapter 3; Petrus Gassendus [Gassendi] in the *Institutio astronomica*, Book 2, chapter 14, and all of Book 3; Io. Hevelius [Johannes Hevelius], *Selenographia*, chapter 7; Baranzanus [Redento Baranzano] in the *Uranoscopia*, pp. 103 and 115. But first we must deal with the number of the heavens, as with the matter of the system.

CAPVT I.

Chapter 1.

Of the number of the total heavens.

[Margin: A single heaven for Aristotle?]

I. The first question usually asked is whether there is a single heaven, or whether several must be asserted. The occasion for this question was given both by Moses, who names a single heaven in the beginning — on which see St Thomas [Thomas Aquinas], part 1, question 68, article 4, and ourselves below, numbers 2 and 3 — and by Aristotle, *De caelo* Book 1, chapter 6, or text 76, where he says: *But let us say why it is not possible either that there be several heavens.* In the same place, however, he understands the world by the name of heaven, the denomination being taken from the principal and by far the greatest part of the world; for he concludes in text 80: *Since this is absurd, it is impossible that there be more worlds than one.* He tries to show this, first, from the name of

Universe, which is commonly attributed to the world: if there were several worlds, the name of Universe would be attributed to one of them wrongly or equivocally. Second, because if every world were of the same species, the earth of one would try to tend toward the earth of another by its weight and its own nature, and fire toward fire; or else the individual elements would be held within the individual worlds by perpetual violence. But the elements of any world must be of the same species — fire, for example, compared with fire — because simple motion, which is due to simple bodies, is either circular, and this belongs to the heaven, or straight; and straight motion is either upward simply, or upward in a certain respect, or downward simply, or downward in a certain respect; and the element that tends simply upward we call fire, and that which tends downward, earth, and so on. Therefore, since no other division of simple motion according to species is possible, it seems impossible too that there should be other elements of a different species. From this discourse it appears that he is speaking of the unity of the world composed of the heavens and the elements. Earlier, however, in chapter 4, text 22, he had distinguished the heaven from the elements, saying: *And so, as though there were some other first body besides earth and fire and air and water, they called the highest place aether, giving it its name from its always running through everlasting time. Anaxagoras, however, misuses this name, and not rightly; for he names aether in place of fire.* Hence it came about that he entitled four books *De caelo*, although in Books 3 and 4 he treats only of the elements. But in the heaven taken strictly, as the place of the stars, or that simple body to which circular motion belongs, Aristotle acknowledges several spheres (*Physics* 8 and *Metaphysics* 12), as we shall show below when explaining the Aristotelian system. Now we must treat of the opinions of others.

[Margin: 1. Opinion: of a single heaven.]

II. The first opinion posited a single heaven, but not in a single sense. For St John Chrysostom held as follows. Because Genesis 1 says, *In the beginning God created the heaven and the earth*; because he knew besides that it is called *Samaim* or *Hasamaim* in the plural number for this reason, that among the Hebrews "heaven" lacks a noun of the singular number, as among the Latins do *Athenae* and *Venetiae*; because he thought besides that this heaven named on the first day was not distinct from the heaven, or firmament, made on the second day; and because he finally held that the whole heaven is immobile, and that the stars are moved not by the motion of the heaven but by themselves within the heaven — for these reasons, I say, he thought that there is a single heaven, taking heaven, however, more strictly, and not including the aerial heaven.

[Margin: St John Chrysostom.]

Accordingly, in homily 4 on Genesis he concludes: *Who, then, after so much teaching, will bear those who dare to speak out of their own brain and, against divine Scripture, to say that there are many heavens?* He has similar passages in homily 12 to the people of Antioch, and in homily 25 on the Epistle to the Hebrews.

[Margin: Tertullian.]

Tertullian was of the same opinion, in his book *Against Hermogenes*.

[Margin: St Bonaventure.]

Speaking, however, of the starry heaven, St Bonaventure (on Book 2, distinction 14, article 1, question 1) acknowledges it as single — and indeed with a unity of continuity — although he admits that several tracts can be marked out in it, according to the plurality of the motions. For he says: *According to the common opinion, whether of the natural philosophers or of the mathematicians, the luminaries are placed in different orbs. But this distinction or diversity of the orbs, according to those who understand better, does not come from a distinction of forms, as air and water are distinguished; nor does it come from a discontinuity of surface, as stone is distinguished from stone; but it comes from a diversity of motions. And a diversity of motions does not take away continuity in what is subtle and fit for motion, as appears manifestly in water, and likewise in air, etc.* Therefore the conclusion is this: *According to this position, then, it must be said that the luminaries of the heaven are placed in several orbs, yet in one continuous body, which Scripture calls by the name of firmament.*

[Margin: Tellez. Tychonics. Copernicans.]

And indeed, whoever hold the starry heaven to be fluid throughout have no reason to divide it into several heavens, but must admit that it is single, as Tycho teaches in the *Epistolae Astronomicae* (p. 149). Oviedus also notes this (the single controversy *De caelo*, point 4, conclusion 5), asserting: *If the heavens are liquid, only one heaven of the wandering and the unwandering stars is to be admitted.* For this reason Tellez (*Philosophy*, disputation 44, section 3, number 5) affirms a single star-bearing heaven. And such are Tycho, Longomontanus, Kepler, Boulliau and, probably, Copernicus, as we shall say in number 14.

[Margin: A single heaven, even though solid.]

But even if the whole starry heaven were held to be solid, Aegidius and Hurtadus nevertheless assert that it is single.

[Margin: Aegidius.]

The former, in part 2 of the *Hexaemeron*, chapter 32, since Scripture says that the stars were placed not in the firmaments but in the firmament, says: *If, then, the luminaries and the stars are in the firmament of heaven, and the planets are counted among the luminaries of heaven, it seems that all the planets are in the firmament of heaven; which could not be, unless the spheres of the planets made one sphere with the firmament, or with the starry heaven.* And a little later: *Yet, if eccentrics and epicycles are posited, nothing prevents all the spheres already mentioned from being one and the same sphere.* And finally he concludes that the deferents of the planets are seven, and that in respect of these the place of the fixed stars can be called the eighth sphere; but that all of them are enclosed in a single heaven — nay, that they are a single sphere — and that it is vain to do through more what can be done through one.

[Margin: Hurtadus.]

But Hurtadus (*De caelo*, disputation 2, section 1) defends a single heaven, notwithstanding its solidity, in such a way that he admits in it, with some older authors, vari- ous channels through which the planets are carried up and down,

to the right and to the left. He does not admit that these are empty, because a vacuum, he says, is a place lacking body but apt to hold a body, whereas those channels are not apt to be filled with body. Against these channels Pererius rises up at length (Book 2 on Genesis, question 9), as do Oviedus (above) and Arriaga (the single disputation *De caelo*, section 4, number 49). And certainly, if one considers the innumerable windings and turnings of the planets, especially of Mars, Mercury and Venus, their whole heaven would have to be hollowed out; nor is it apparent how light could be transmitted to us from the whole hemisphere of the planet's body through those cavities, if light is an accident needing a subject; and so we would see a single point of them.

[Margin: Cisalpinus, Aversa, Tannerus.]

In another way, a single heaven was asserted by Andreas Cisalpinus [Andrea Cesalpino] (*Peripateticae quaestiones*, Book 3, question 4) and Raphael Aversa (*Physics*, question 32, sections 6 and 7), and Tannerus did not think it improbable (*Theology*, volume 1, disputation 6, question 3, doubt 3, number 78): namely, that the starry heaven is a single sphere, in which, however, there are different circles interlocked with one another like rings, or zones within the zodiac carrying the planets forward and back, up and down, without fluidity or vacuity. Finally, all who accept three heavens taken broadly — namely the Empyrean, the starry and the aerial, of which we shall speak in number 5 — would seem to favour the unity of the starry heaven, for by that very fact they would seem to make the starry heaven single; and Tellez too uses this argument. But, as we shall see partly in number 5 and partly in number 7, many of them subdivide the starry heaven into several really distinct heavens.

[Margin: 2. Opinion, for a plurality of heavens.]

III. The second opinion affirms absolutely that there are several heavens. Against these — some mathematicians or other — St Basil, in homily 3 on the *Hexaemeron*: *Since those*, he says, *who are accustomed to use demonstrations are of much greater weight, and have confirmed by the force of geometrical proofs that conclude necessarily that nature cannot bear to establish another heaven besides this one, then indeed we shall laugh all the more freely at the linear trifles of those mathematicians, contrived with whatever art and ingenuity, etc.* But perhaps they were using the Aristotelian arguments put forward in number 1 to show that there are not several worlds. Certainly divine Scripture indicates that there are several heavens, when it says in Book 1 of Paralipomenon [Chronicles], chapter 2: *If heaven and the heavens of heavens do not contain you*; and in Psalm 113: *The heaven of heaven is the Lord's*; and in Psalm 148: *Praise him, you heavens of heavens*; and in Ecclesiasticus 16: *Behold the heaven and the heavens of heavens.* Moreover, sacred Genesis mentions two heavens, according to the more common opinion of the Fathers (on which see section 1, chapters 1 and 2): namely the Empyrean, or even the starry heaven, created on the first day, and the firmament made on the second day; and St Paul, in 2 Corinthians 12, mentions three heavens.

[Margin: St Athanasius.]

Pointing to these arguments, St Athanasius said in the *Questions to Antiochus*, question 5: *How many are the heavens? I answer: this question is in doubt among many. For the book of Genesis mentions two heavens; the divine Paul, however, says that he himself saw even a third heaven, and David the prophet speaks of a fourth heaven: Praise him, you heavens of heavens. But it must be understood that, just as human nature is called one and man is called one, and yet there are many men, so too the nature of the heavens is one, and in divine Scripture both one heaven and many heavens are spoken of.* Nor, indeed, do these writers differ in substance from those who posit one heaven, but only in name, as St Thomas teaches (part 1, question 68, article 4): for St Chrysostom takes by the name of heaven the whole space that lies above the earth and the water, while the others distinguish several heavens within it.

[Margin: The error of Basilides concerning 365 heavens.]

It is not permitted, however, to multiply heavens at will; and so the error of Basilides, who posited as many heavens as there are days in the year, namely 365, is numbered among the heresies by St Irenaeus (*Against Heresies*, Book 2, chapters 21 and 22), by Tertullian (in the book *On the Prescription of Heretics*), by St Epiphanius (in the *Panarion*, Book 1, heresies 24 and 26) and by St Augustine (in the book *On Heresies*, heresy 4) — granted that this heresy consisted not so much in the size of the number as in the production; for, as St Irenaeus relates, he imagined the second heaven procreated from the first, the third from the second, and likewise the others by successive birth. So our Tellez wittily said (disputation 44 of his *Philosophy*, section 3, number 4): *Although he admits so many heavens, into none of them, as I rather think, will he be admitted; for he was a heresiarch, and therefore deserved to be banished not into heaven but into infernal Tartarus.* Leaving this aside, then, let us see how many heavens others have counted.

IV. The third opinion counts only two heavens, but not in the same sense.

[Margin: 3. Opinion [?], of 2 heavens [?].]

For St Clement (Books 1 and 2 of the *Recognitions*), Acacius (in Lippomanus, in the *Catena*) and Theodoret (on chapter 9 of the Epistle to the Hebrews, and question 11 on Genesis) affirm one heaven, the Empyrean, or the one created on the first day, and another made on the second day.

[Margin: St Clement [?]. Acacius. Theodoret [?].]

Let us hear Theodoret: *Since divine Scripture teaches that in the beginning God created the heaven and the earth, and then says that after the creation of light the firmament was made on the second day, a question of this kind (about the number of the heavens) seems full of ignorance. For one ought to have known the diversity of the heavens from the reckoning of time and from the very manner of creation: the one before light, the other after light; and the former made not from other matter, the latter from the waters, etc. Whoever, then, does not believe that there is a second heaven strays from the straight path; but whoever tries to count more clings to fables, setting aside the teaching of the divine Spirit.*

[Margin: Claudianus Mamertus [?]. Suidas.]

In the same sense Claudianus Mamertus (*De statu animae*, Book 2, chapter 13) said that there are two heavens. Likewise Suidas, in his historical work: *There are two heavens: one procreated together with the earth, the other which was commanded to stand in the midst of the waters, which they also called the firmament.*

[Margin: Procopius [?].]

And Procopius, speaking of the heaven made on the second day, says on Genesis chapter 1: *Some deny that the generation of a second heaven is depicted here. For they think the present sequence of words is a rather brief repetition of the heaven spoken of above. These and such things they dare to babble, although Scripture brings forward another name and another use for this second heaven.*

[Margin: St Bruno [?].]

The same understanding of these two heavens is found in St Bruno, in the book *De novis*, chapter 2.

[Margin: Anastasius [?].]

But Anastasius Synaita puts it most elegantly, joining the mystical sense with the literal (*Commentary on the Hexaemeron*, Book 2): *On the first day was made the veil of the upper heaven, which draws near to the Holy of Holies, where Christ entered as forerunner for us. For that reason, moreover, on the second day is made the second and outer veil, which is called the firmament in the midst of the water, and which is indeed the firmament of faith in Christ.* Then, after a few words: *We have learned from sacred Scripture, then, of the making of only two heavens, as a type and figure of the two veils of the Temple, which signify the two natures of Jesus, and the two peoples, and the two Churches, etc.*

[Margin: Mastrius and Bellutus [?].]

Lastly, Mastrius and Bellutus (*De caelo*, disputation 2, question 1, article 2, number 30) admit a primum mobile really distinct from the starry heaven, but in such a way that they say the starry heaven is single and continuous, and they account for the various motions of the planets not through whole heavens or spheres but through circles or rings and zones contained within the zodiac.

[Margin: St Gregory of Nyssa [?].]

In another way, St Gregory of Nyssa, in his *Hexaemeron*, especially toward the end, teaches that a single heaven was made on the second day, once the fiery element had been separated from the others, and that this heaven was divided into two regions, one for the unwandering stars, the other for the wandering.

[Margin: St Justin [?].]

And finally, in yet another sense, St Justin (*Questions of the Orthodox*, question 57) says that there are indeed two heavens, but that these are divided into various spaces, which Scripture calls heavens; he is speaking, however, of the aetherial heaven and the aerial. For he asks: *If Moses had set forth to us the creation of a twofold heaven, how does Scripture teach that there are more, saying at one time "the heavens of heavens", at another "the heavens were opened to him"?* Then he answers: *Moses indeed spoke of heavens, but in number he handed down neither one, nor two, nor more. Divine Scripture, moreover, is accustomed to call the upper intervals of the parts heavens — as the birds of the heaven, and the eagles in the heaven, and the*

stars of the heaven. From these sayings, then, it follows that we are to understand the heavens as two in substance, but more by their intervals. And if we take heavens in this way, there will be no contradiction in the words. Two heavens, then, are held by Theodoret, Claudianus, Suidas, Procopius, Bruno and Anastasius — the Empyrean and the starry; by Nyssenus, the heaven of the fixed stars and that of the planets; but by St Justin, the aetherial and the aerial; and by Mastrius and Bellutus, the primum mobile and the starry heaven. But if you bring in the aerial heaven, St Nyssenus will acknowledge a third heaven, as we shall show in the next number.

[Margin: 4. Opinion [?], of 3 heavens [?].]

V. The fourth opinion, and the most celebrated among the sacred writers, was and still is that of three heavens. It arose from that saying of St Paul in 2 Corinthians chapter 12: *I know a man in Christ fourteen years ago — whether in the body or out of the body I do not know, God knows — caught up thus to the third heaven*; words which St Thomas expounds most learnedly (II-II, question 175, articles 3 and 4, etc.). Although, as Oviedus notes at the end of the controversy *De caelo*, some have believed that "three heavens" were put for many or for all, in the way in which, in Amos 1, it is said, "for three crimes of Damascus", that is, for very many; and in 2 Corinthians 11, "Three times I besought the Lord", that is, several times.

[Margin: Three metaphorical heavens [?] — three visions.]

Nevertheless the common opinion is that the three heavens enumerated are really three in their whole extent, speaking properly. For metaphorically, as St Augustine interprets (volume 3, Book 12, chapters 29 and 34), they can be understood as three kinds of supernatural vision, namely corporeal, imaginary and intellectual; and so St Paul, passing beyond corporeal and imaginary vision, was raised to intellectual, and indeed intuitive, vision of God — which some call the heaven of the Trinity. It was to this heaven, that is, to the beatific vision, as though it were owed to his natural excellence, that Lucifer strove not to be raised but to raise himself, when he said, "I will ascend into heaven", as Martinengus thinks (*Glossa magna*, page 623), and before him St Thomas (part 1, question 68, article 4). But literally these three heavens are either the aerial, the starry and the Empyrean; or the first, made on the first day, the second, made on the second day, and the third, to which St Paul was caught up. But let us recite the words of the Fathers.

[Margin: St Basil.]

St Basil, in homily 3 on the *Hexaemeron*: *In the second place there offers itself for inquiry whether this firmament is different from the heaven that was made in the beginning, since it too has been allotted the name of heaven; and accordingly whether two heavens are to be posited at all.* And at length he replies: *We, on the contrary, are so far from doubting at all about two that we would even inquire into a third, of whose contemplation that admirable Paul was held worthy. Moreover, when the Psalm expressly mentions the heavens of heavens, it has surely implanted in us a clear understanding not of one heaven only, but of several.*

[Margin: St Ambrose.]

St Ambrose, as usual, agrees with him (Book 2 of the *Hexaemeron*, chapter 3), where he finally lays it down thus: *Therefore we cannot deny that there is not only a second but also a third heaven, since the Apostle confirms by the testimony of his writings that he was caught up to the third heaven. David, too, set the heavens of heavens in that choir of those who praise the Lord.*

[Margin: Cassiodorus.]

With them Cassiodorus also agrees, on Psalm 148.

[Margin: St Damascene.]

But what these three heavens are, St Damascene taught more openly (Book 2 of the *Orthodox Faith*, chapter 6). For when he had said: *Since, then, Scripture speaks of heaven, and of the heaven of heaven, and of the heavens of heavens, and affirms that blessed Paul was caught up as far as the third heaven, we say that in the creation of the whole world the making of heaven is understood by us to be that sphere which certain of the wise (who are not of ours) call starless, making their own those doctrines which are Moses'; and then that God also called the firmament heaven* — he added: *The heaven of heaven, then, is the first heaven, set above the firmament. Behold two heavens, for God also called the firmament heaven. It is also the custom of divine Scripture to call the air heaven, from its being seen above. For "Bless," it says, "all you birds of heaven", meaning the air; for the air is the path of flying creatures, and not heaven. Behold the three heavens of which the divine Apostle spoke.*

[Margin: St Gregory of Nyssa.]

St Gregory of Nyssa, however, distinguished these three heavens under another notion, in *On the history of the six days*, in these words: *I think, then, that the outermost part of the sensible world is called the third heaven by St Paul, who divides whatever appears into three parts, etc. One heaven Scripture names the boundary of the denser air, as far as the winds and clouds reach and the nature of high-flying birds is borne, etc.; then it names another both heaven and firmament — that which is seen within, beneath the sphere of the unwandering stars, in which the wandering stars move. And the very extremity of the sensible world, which is the border of his creation that is perceived by thought, it names firmament and heaven.* For Nyssenus, therefore, the first heaven is the aerial, the second the planetary, the third the firmament of the unwandering stars.

[Margin: St Thomas.]

[Margin: Caietanus.]

Differently again, St Thomas (part 1, question 68, article 4) says that these three heavens are the Empyrean, which is wholly luminous; the aqueous or crystalline, which is totally transparent; and the starry, partly luminous and partly transparent. Differently once more, Caietanus (on Genesis, and on 2 Corinthians chapter 12) took these three heavens: in the third place he substituted the aqueous heaven for the Empyrean, saying: *In sacred Scripture mention is made of three heavens. The lowest is the aerial heaven, according to the words "the birds of heaven"; the middle is the starred heaven, of which it is said at the beginning of Genesis, "and he set them in the firmament of heaven"; the third and*

highest is the waters, all those that are above the heavens, which Scripture mentions many times, and which we call the aqueous heaven, while the philosophers call it the primum mobile. For the Empyrean heaven, handed down by later writers, is found nowhere in Scripture. But how falsely he excludes the Empyrean we have said sufficiently in section 1, chapter 1, from number 24.

Most of the more recent writers, however, subscribed to Damascene's understanding: first of all Suarez (*De opere sex dierum*, Books 1 and 2), Oviedus (the single controversy *De caelo*, point 4, number 12), Tannerus (in the dissertation *De caelis*, question 10), Christophorus Borrus [Cristoforo Borri] (folio 260 of his *New Astronomy*) and Genebrardus [Gilbert Génébrard] as cited by him, and Hurtadus (disputation 2 *De caelo*, section 1): namely, that heaven is divided into the Empyrean, the starry and the aerial. Not all of them, however, deny the subdivision of the starry heaven into several heavens; on the contrary, Saints Basil, Ambrose and Damascene subdivide it into eight heavens, as we shall see below. That the air too is designated by the name of heaven among heathen and profane writers, I have already shown (section 1, chapter 1, number 14).

[Margin: 5th opinion, of 4 heavens.]

VI. The fifth opinion, of four heavens, is hinted at by St Athanasius (question 5 to Antiochus), whose words I have already copied out in number 3. He seems to understand the Empyrean, the firmament of the unwandering stars, the heaven of the planets and the aerial heaven; but he does not express his meaning clearly enough.

[Margin: 6th opinion, of five heavens.]

VII. The sixth opinion is of 5 heavens: namely that of Oviedus (the single controversy *De caelo*, point 4, number 10), where he says, not absolutely but on the supposition that the heaven of the stars is solid, that it must be divided into five heavens, namely those of the fixed stars, of Saturn, of Jupiter, of the Sun and of the Moon. For since Mars, Venus and Mercury move now above the Sun, now below it, he thinks they are enclosed within one and the same heaven of the Sun, as though it were common to these four planets. Absolutely, however, he inclines to fluid heavens, and therefore in number 12 he posits three heavens: the Empyrean, a single starry heaven without subdivision, and the aerial. Hence, if he had added the Empyrean and the aerial to the five solid heavens, he would indeed have made 7 heavens, assembled from solid and fluid.

[Margin: 7 heavens.]

But we shall assert 5 heavens below in another way: namely the Empyrean; the aqueous or crystalline; the solid firmament of the fixed stars; the aether, or fluid heaven of the planets; and the aerial.

[Margin: 7th opinion, of 6 or 7 heavens.]

[Margin: Philastrius.]

VIII. The seventh opinion is of 6 heavens, which Philastrius heaps together with other opinions in his book *On Heresies*, saying: *Concerning the diversity of the heavens there is a heresy which is in doubt*; and a little later: *If, then, anyone wishes to accept six heavens according to David, and this firmament as the seventh, he*

does not err. For Solomon speaks of three heavens thus: heaven, and the heaven of heaven; Paul the Apostle likewise declares that he was caught up as far as the third heaven. If, then, anyone accepts seven, as David does, or three, or two, he does not err, etc.

[Margin: Bede.]

[Margin: Rabanus.]

Otherwise Bede (on Genesis chapter 1), having quoted the verse

The golden-hued aether of the sevenfold heaven is parted,

at once adds: *For these are the names: air, aether, Olympus, the fiery space, the firmament, the heaven of the Angels, the heaven of the Trinity.* The same order of the heavens, but reversed, is given by Rabanus [Hrabanus Maurus], as it is also given by St Thomas (on Book 2 of the *Sentences*, distinction 14, question 4, and part 1 of the *Summa*, question 68, article 4): namely the Empyrean, the crystalline, the starry, the fiery, the Olympian, the aethereal and the aerial. And in the same place he says, following Rabanus on Genesis chapter 1, that the space from the Earth to the Moon is divided into four regions, as though into four heavens, and that the upper region of fire is called the fiery heaven; the lower region of fire, the Olympian heaven; the upper region of air, the aethereal heaven; and the lower region of air, the aerial heaven. And perhaps someone might draw in here the "heptachord of the world" which Virgil indicates in these verses:

[Margin: Eclogue 2.]

I have a pipe, joined from seven unequal hemlock stalks, etc.

And this:

He sounds the seven distinct notes against the measures.

[Margin: 8th opinion, of 8 heavens — but of the stars [?].]

IX. The eighth opinion was of eight starry heavens. All those held it who thought that the fixed stars are moved by no motion other than that of the primum mobile. Hence, since they posited as many heavens as there are planets, 7, the sphere of the fixed stars, or the Aplanes, turned out for them to be the highest and eighth sphere, which was afterwards called the Firmament by many Catholics. Not all Catholics, however, excluded the Empyrean or crystalline heaven, or even the aerial; but, speaking of the subdivision of the starry heaven, they distributed it into 8 total spheres.

[Margin: The Babylonians. The Egyptians. Eudoxus. Callippus. Plato. Aristotle. Cicero. Philo. St Damascene. St Bonaventure. Carthusianus. Abenezra.]

Of this opinion were the most ancient Babylonians and Egyptians, Eudoxus, Callippus, Plato, Aristotle, Cicero, Philo, St Damascene, St Bonaventure, Dionysius Carthusianus and Abenezra, as I have already shown (section 2, chapter 3, number 2), where I adduced the words of Plato, Cicero, Philo and Damascene. He, indeed, in Book 2 of the *Faith*, chapter 6, having accepted three heavens — the Empyrean, the starry and the aerial — adds concerning the

starry heaven of the planets: *If, however, you wish to take seven circles for seven heavens, you will in no way offend against the account of truth.*

[Margin: St Basil.]

Similarly St Basil, concerning the seven heavens of the planets (homily 3 on the *Hexaemeron*), asserts the most common opinion: *Nor is it right that this should ever be believed with less faith than that with which we believe that there are seven orbs, in which the seven stars are proclaimed, by the almost unanimous voice of all, to run their course; and these heavens, indeed, they assert are neatly fitted one into another, as if jars or small vessels were set one inside another.* He had, however, admitted three heavens on the authority of St Paul, and among them the Empyrean and the Firmament.

[Margin: St Ambrose.]

So too had St Ambrose (Book 2 of the *Hexaemeron*, chapter 2), and he then adds: *David, too, set the heavens of heavens in that choir of those who praise the Lord. Imitating him, the philosophers introduced the harmonious motion of the seven stars, of the Sun, the Moon, etc., etc.; and they think that these, linked and as it were inserted into one another, turn backward and are carried with a motion contrary to the rest.*

[Margin: Remigius.]

To these must be added Remigius of Auxerre [Remigius Antisiodorensis], on Psalm 148, explaining the words "Praise him, you heavens of heavens": *Heavens, that is, the firmament and the aether, taken collectively [?]; of heavens, that is, of the seven circles, where the aplanes and the planets are fixed: may they be for you matter for praising the Lord.*

[Margin: St Thomas.]

On the same principle St Thomas, who asserts three heavens — the Empyrean, the crystalline and the starry — speaks thus of the starry heaven (part 1, question 68, article 4): *The third, partly transparent and partly luminous in act, which they call the starry heaven; and it is divided into eight spheres, namely into the sphere of the fixed stars and the seven spheres of the planets, which can be called seven heavens, or seven spheres.*

[Margin: Lyranus.]

[Margin: Tostatus.]

Here Lyranus joins them, in his *Postills* on Genesis, saying: *The firmament was made according to the specific form of the starry heaven. In this production the seven orbs of the planets, which are comprehended under the name of firmament, are also understood to have been produced.* Nor does Tostatus say otherwise, on chapter 1 of Genesis: *By the name of Firmament is taken the whole celestial magnitude, or mass, containing eight orbs: namely the starry heaven, and the heavens of Saturn, Jupiter, Mars, the Sun, Venus, Mercury and the Moon.*

[Margin: Dionysius Carthusianus.]

[Margin: Burgensis.]

Likewise Dionysius Carthusianus, in his *Commentaries* on Genesis, article 10: *The firmament was made, that is, the starry heaven, which is the eighth sphere, because beneath it are the seven spheres, or orbs, or heavens of the planets.* With him

Burgensis agreed, in his *Additions* on Genesis chapter 1: *The firmament with which we are dealing here is the starry heaven, which is divided into the eighth sphere, that of the fixed stars, and into the seven orbs of the planets.*

[Margin: Riccius.]

[Margin: Orontius.]

Augustinus Riccius, on the other hand (the treatise *On the motion of the eighth sphere*, chapters 13 and 14), and Orontius [Oronce Finé] (Book 1 of the *Sphere*, chapter 5) do acknowledge an apparent motion of the fixed stars toward the east, but teach that it arises from the aggregate of 8 heavens.

[Margin: Arriaga.]

[Margin: Amicus.]

[Margin: Aversa.]

[Margin: Cremoninus.]

[Margin: Rubius.]

[Margin: Hurtadus.]

And our own Rodericus Arriaga [Rodrigo de Arriaga] (the single disputation *De caelo*, section 4, number 52), on the hypothesis that the starry heavens are solid, teaches that there are eight of them; for he thinks the eighth sphere can be moved by the Intelligences in such a way that there appears to be a twofold motion in it, one to the west, the other to the east. Amicus also thinks this the more probable view (treatise 4 *De caelo*, question 5, doubt 2), and so does Aversa (question 32 of the *Philosophy*, section 4). Eight heavens are likewise affirmed by Cremoninus [Cesare Cremonini] (*De motu caeli*, section 2, chapter 13), Rubius (Book 2 *De caelo*, chapter 5, question 1) and Hurtadus (disputation 1 *De caelo*, section 1), because they think it uncertain whether the fixed stars have a proper and peculiar motion. Arriaga, however, acknowledges a ninth heaven above the starry ones, namely the Empyrean.

[Margin: 9th opinion, of 9 heavens.]

X. The ninth opinion, of nine heavens, does not count them all in the same way. For Arriaga, as I have just said, counts the Empyrean and eight starry heavens. But others held that the ninth heaven is the primum mobile, which carries along with itself the eight lower spheres, of the fixed stars and of the 7 planets; and to each of these they attributed its own proper motion toward the east — to the fixed stars a very slow one.

[Margin: Macrobius. Alpetragius. Rabbi Isaac. Rabbi Moyses. Zagutus. Haly. Scotus. Sacrobosco.]

So Macrobius (Book 1 on the *Dream of Scipio*, chapter 17); so Rabbi Isaach, Alpetragius (in his *Celestial Physics*), Abraham Zagutus [Abraham Zacuto] and Rabbi Moyses, as cited by Riccius (the treatise *On the motion of the eighth sphere*, chapter 4); Haly (chapter 11 of the *Quadripartitum*); Scotus [John Duns Scotus] (on Book 2, distinction 14, question 2, and Book 12 of the *Metaphysics*, comment 44); and Io. de Sacro Boscho [Johannes de Sacrobosco] (on chapter 1 of the *Sphere*). And Mastrius and Bellutus, Scotists, say that it was the common opinion in Scotus's time (disputation 2 *De caelo*, question 1, article 2, number

30). They indeed admit a primum mobile distinct from the starry heaven, though they posit the eight starry heavens as a single solid and continuous heaven, with various circles or zones carrying the planets, following Aversa and Cesalpino; as does Chiaramonti too (Book 2 *De universo*).

[Margin: Whether Hipparchus [?] and Ptolemy [?] … this [?] … — the note's ends are lost into the binding.]

Averroes (on Book 2 *De caelo*, comment 67), Albert the Great (Book 2 *De caelo*, treatise 3, chapter 11), Clavius (on the *Sphere*, page 43), the Conimbricenses [the Coimbra commentators] (Book 2 *De caelo*, chapter 5, question 1) — who attribute the same opinion to Menelaus, or Mileus, to Agria, to Alexander and to Alfraganus — Scheinerus (*Disquisitiones mathematicae*, page 50), Tannerus (dissertation *De caelo*, question 10), and Mastrius and Bellutus (disputation 2 *De caelo*, question 1, article 2, number 19) think that the authors of this opinion were Hipparchus and Ptolemy. That is to say: Hipparchus and Ptolemy were the first who, by comparing their own observations of the fixed stars — Hipparchus with those of Timocharis and Aristyllus, Ptolemy with the observations of Hipparchus — detected and confirmed that the fixed stars, besides their apparent motion upon the poles of the equator toward the west, are slowly advanced in the order of the signs toward the east, upon the poles of the ecliptic. But if you read Ptolemy (Book 1 of the *Almagest*, chapter 8, and Book 7, chapters 2 and 3) and Alfraganus (differences 5 and 18), where they treat of these motions, you will nowhere find that they posited two distinct spheres, but only distinct poles about which those motions take place. And Tannerus himself concedes that the argument for a distinction of heavens drawn from the distinction of motions is not necessary, but that a heaven can be moved by one Intelligence or by several with a single real motion in such a way that the motion nevertheless appears twofold. Indeed, Ptolemy and Alfraganus seem to describe the equator and the ecliptic in the same heaven.

[Margin: 10th opinion, of 10 heavens.]

XI. The tenth opinion asserted 10 heavens: namely seven for the seven planets; the eighth for the motion of trepidation, or of access and recess, of the fixed stars toward rising and setting; the ninth for the motion of the fixed stars and of the auges, or apogees, of every planet except the Moon; and the tenth for the motion of the primum mobile.

[Margin: Alphonsus. Amicus. Fernelius [?]. Purbachius. Regiomontanus. Apianus [?]. Maurolycus. Langius. Thebith. Arzachel. Isaac.]

So King Alfonso [Alfonso X] in his tables; Io. Baptista Amicus (*De motibus caelestibus*, the last chapter); Io. Fernelius (Book 2 of the *Cosmotheoria*, chapters 1 and 7); Purbachius in the *Theory of the eighth sphere*, with his followers; Regiomontanus (in the same place, and Book 7 of the *Almagest*, proposition 7); Maurolico (dialogue 1 of the *Cosmographia*, page 24, and dialogue 3, page 89); Apian (in the *Opus Caesareum*); and Ioseph Langius [Joseph Lange] (*Elementa astronomica*, chapter 4). The same number, but in another way, was accepted by Thebit, Arzachel and Isaac Israelita [Isaac Israeli]; but they assigned the motion

of trepidation in longitude rather to the ninth sphere, and the continuous motion in longitude, of itself, to the eighth. To this class could be reduced those authors who posited 11 heavens in such a way that they called the eleventh the Empyrean — namely the Conimbricenses, Martinengus, Clavius and, before them, Alliacensis, as we shall say shortly; for in the number of 10 mobile spheres they agree with the Alphonsines.

[Margin: Parisiensis.]

[Margin: Delphinus.]

But Gulielmus Parisiensis (first part *De universo*, chapters 34 and 37) admits a first heaven, most perfectly at rest and immobile, or Empyrean, and nine other mobile heavens, namely the primum mobile and the eight remaining spheres; and the same view is defended by Io. Antonius Delphinus (the book *De caelestibus globis ac motibus*, chapters 30 and 32).

[Margin: 11th opinion, of 11 spheres.]

XII. The eleventh opinion is of eleven heavens, but not in the same way. For some count, with the Alphonsines, ten mobile spheres, according to what was said a little earlier in number 11; but above this they acknowledge an eleventh, immobile sphere: namely the Empyrean, or supreme immobile heaven, which pours diverse and stable properties into the different regions of the Earth.

[Margin: Alliacensis. Clavius. Conimbricenses. Martinengus. Polaccus.]

So Petrus Alliacensis (question 2 on the *Sphere*), Clavius (on the *Sphere*, page 45), the Conimbricenses (Book 2 *De caelo*, chapter 5, question 1), Ascanius Martinengus (*Glossa magna*, page 1021) and Georgius Polaccus [Giorgio Polacco] (*Anticopernicus*, assertion 172). But among these, Alliacensis reports the opinion of 10 mobile heavens and does not reject it, and adds that besides them an eleventh, immobile heaven is required because of the diverse influences — which Clavius too thinks probable. Again, Clavius thinks that this same heaven is that Empyrean of which Strabus [Walafrid Strabo] and Bede speak; but he thinks that the aqueous or crystalline heaven is the aggregate of the ninth and tenth heavens of the Alphonsines.

[Margin: Io. Vernerus.]

Others, however, posited eleven heavens, but all mobile: namely the eleventh, or primum mobile; the tenth for the first trepidation, or libration, in latitude, by force of which the obliquity of the ecliptic varies by turns; the ninth for the second libration, or trepidation, in longitude, by force of which the equinoctial points seem to advance and to recede [?], and so the motion of the fixed stars in longitude seems to be quickened and retarded; the eighth for the proper and uniform motion of the fixed stars in the order of the signs; and the remaining seven for the motion of the seven planets in longitude, etc. So Io. Vernerus [Johannes Werner], as cited by Erasmus Osualdus [Erasmus Oswald Schreckenfuchs] in the *Theory of the Eighth Sphere*;

[Margin: Leopoldus, Maginus, Clavius.]

Leopoldus de Austria [Leopold of Austria] in his *Compilatio*; Ioannes Antonius Maginus in his *Theorics*, Book 1, and on the second movables; and Clavius,

in the last edition of the *Sphere*, on account of the motions already mentioned, asserted by Copernicus but transferred to the hypothesis of a resting Earth — which is why Scheinerus calls this system the Clavian (*Disquisitiones mathematicae*, page 36). This same number is set out, not on their own opinion but on that of others, by Antonius Deusingius [Anton Deusing] and Petrus Gassendus [Pierre Gassendi] in their *Institutiones astronomicae*.

[Margin: 12 heavens.]

Hence, since Clavius admitted the Empyrean heaven, he certainly admitted 12 heavens.

[Margin: Tannerus's slip.]

XIII. But since the assertion of eleven heavens is attributed to Copernicus by Tannerus (dissertation *De caelis*, question 10, and volume 1 of the *Summa theologica*, disputation 6, question 4, doubt 4, number 6), it should be understood that Copernicus acknowledged this number not on his own opinion but on that of others. For he says in Book 3 of the *Revolutions*, chapter 1: *On account of these, some devised a ninth sphere, others a tenth, through which they thought these things came about in this way; and yet they could not deliver what they promised. And now an eleventh sphere too had begun to come to light — a number of circles that we shall easily refute as superfluous by means of the motion of the Earth.*

[Margin: 2 heavens in the hypothesis of Copernicus, or a single one.]

Copernicus [?], then, attributes all the apparent motions in the fixed stars, the very motion of the primum mobile, and the variation of the obliquity of the ecliptic to the motions of the Earth, as I shall show more fully in section 4. Nor are the heavens distinct in his hypothesis except into two classes: namely into the immobile sphere of the fixed stars, and into the fluid heaven of the planets, among which planets is the Earth with the sphere of the elements. For although he did not state that fluidity expressly, it is gathered by no slight conjectures from what he teaches in Book 1, from chapter 8 to 11. In chapter 8 he teaches that not the whole air is carried round together with the Earth in the annual motion, but only the air that is near us. Just as the Earth, therefore, which is one of the planets, revolves with the nearby air within the rest of the air, which is fluid but unmoved, so it is fitting that the same should happen to the other planets too — that is, that they move in a fluid aethereal breeze. Again, in the same place he says that immobility befits the world as the place of the stars and planets, and that it is absurd to ascribe motion to what contains, or locates, and not rather to what is contained and located, which is the Earth. But if this reasoning holds, it holds also of any heaven with respect to its own planet, whose place it is; nor can the sphere of the fixed stars alone be understood by the name of the world. Finally, in chapter 10 he names the sphere of the fixed stars; but while he inquires into the order of the celestial orbs he never names the spheres of the planets, only the planets themselves and their revolutions — indicating clearly enough that they revolve not at the motion of orbs but of themselves. What indicates this most of all, however, is that the Earth with the Moon is carried through the annual orb, and yet the Moon does not cut it:

from this argument Boulliau (Book 1, chapter 8) concludes that the Moon and the planets move freely through a fluid aether. Accordingly, in the Copernican system we recognise two heavens in reality, one of the fixed stars and the other of the planets, the latter, however, being distinguishable in reason and designation into seven heavens — granted that Longomontanus (Book 1 of the *Theorics*, chapter 1) thinks that Copernicus, having removed the Ptolemaic epicycles, nevertheless retained the eccentricity of the orbs with their reality intact, and that Tycho (volume 5 of the *Progymnasmata*, page 439) thought the same of Copernicus, though timidly.

[Margin: Corollary from Pererius.]

From what has been said it is clear enough how prudently Pererius said (Book 2 on Genesis, question 4) that none of the opinions already mentioned, except the error of Basilides, is repugnant to Scripture or to the Fathers.

CONCLVSIO.

Conclusion.

XIV. *Heavens taken broadly are five: namely the Empyrean, the aqueous or crystalline, the firmament of the fixed stars, the aether of the planets, and the air. Taken strictly, however, they are only two, if we are speaking of heavens really distinct: namely the firmament and the aether, or the heaven of the fixed stars and the heaven of the planets.* For that the Empyrean is above all the heavens we have shown sufficiently in section 1, question 6, from number 24. That there is, besides, an aqueous or crystalline heaven above the whole firmament, whether it be fluid or solid, I taught in section 1, chapter 2, questions 1 and 3, and chapter 3, conclusion 4. Further, that the firmament of the fixed stars is solid and the aether of the planets fluid, I likewise taught in section 1, chapter 3, conclusion 4, and chapter 7, number 21. And so the heaven of the fixed stars is indeed to be distinguished from the planetary heaven; but for the planetary heaven, since it is continuous, there is no reason to distinguish it really, any more than to distinguish the air or water into several individuals because different birds or fish move in them. Finally, that the aerial heaven, or the air, is called heaven by both sacred and profane writers — broadly indeed, but properly — is clear from what was said in section 1, chapter 1, number 9, and in section 3, this chapter 1, number 5. But if you take heaven strictly for a simple visible body in which the stars move, it follows that there are only two: namely the solid heaven of the fixed stars and the aerial [?] heaven of the planets; and these are also distinguished from each other in their species as heavens, since the firmament is of water and the aether of the planets of fire, as I taught in section 1, chapter 3, conclusion 4. If anyone, however, wishes to distribute the fluid heaven into one region for the new phenomena, into the heaven of Saturn, the heaven of Jupiter, the heaven of the Sun with its satellites Mars, Venus and Mercury, and the heaven of the Moon, I do not object; indeed I admitted this in Book 7, section 6, chapter 4, scholium 5.

[Margin: The specific difference of the heavens.]

On the specific difference of the heavens, however, others hold differently, as may be seen in Suarez (disputation 13 of the *Metaphysics*, section 11), Amicus (treatise 4 *De caelo*, question 7, doubt 1), the Conimbricenses (Book 2 *De caelo*, chapter 5, question 3, and chapter 7, question 1), Pontius (disputation 22, question 7), Mastrius and Bellutus (disputation 2 *De caelo*, question 2, article 4), Arriaga (the single disputation *De caelo*, section 1) and Tannerus (volume 1 of the *Theology*, disputation 6, question 4, doubt 4).

XV. Now, since among other writers this dissertation on the number of the heavens, and their distribution, is very incomplete or confused, it seemed good to put together a brief synopsis of the preceding opinions and to gather it into the following catalogue, adding a brief little explanation for the subdivision of the opinions into their classes. Their authors, however, I have already listed in their places from number 1 onward.

SYNOPSIS Numeri cælorum iuxta diuerſos Auctores.

Synopsis of the number of the heavens according to various authors.

Number of heavens		Number of the paragraph
I.	A single heaven, that is, a single world. *Aristotle.*	1
	A single starry heaven, as being fluid. *St Chrysostom, Tertullian, St Bonaventure, Tycho, Longomontanus, Kepler, Boulliau, Tellez.*	2
	A single starry heaven, though solid. *Aegidius, Hurtadus, Cesalpino, Aversa.*	2
II.	Two heavens: that is, the Empyrean, or the heaven created on day 1, and the Firmament, made on day 2. *St Clement, Acacius, Theodoret, Anastasius Synaita, Procopius, Suidas, St Bruno, Claudianus Mamertus.*	4
	Two heavens: the starry and the aerial. *St Justin.*	4
	Two heavens: of the fixed stars and of the planets. *St Gregory of Nyssa.*	4
	Two heavens: the primum mobile and the starry. *Mastrius and Bellutus.*	4
III.	Three heavens: namely the Empyrean, the starry and the aerial. *Saints Basil, Ambrose, Damascene; also Cassiodorus, Genebrardus, Suarez, Tannerus, Hurtadus, Oviedus, Tellez, Borrus.*	5
	Three heavens: of the fixed stars, of the planets, and the aerial. *St Gregory of Nyssa.*	5
	Three heavens: the Empyrean, the aqueous and the starry. *St Thomas Aquinas.*	5
	Three heavens: the aqueous, the starry and the aerial. *Caietanus.*	
	Three heavens, but mystically three supernatural visions: corporeal, imaginary, intellectual. *St Augustine.*	
IV.	Four heavens: the Empyrean, that of the fixed stars, that of the planets, and the aerial, hinted at by St Athanasius.	6
V.	Five starry heavens: of the fixed stars, of Saturn, of Jupiter, of the Sun (with the inclusion	7

Number of heavens		Number of the paragraph
	of Mars, Venus and Mercury) and of the Moon, if they are solid. *Oviedus.*	
V.	Five heavens, taken broadly: the Empyrean, the aqueous, that of the fixed stars, that of the planets, and the aerial. *Ourselves.*	7
	Seven heavens, confusedly. *Philastrius.*	8
VII.	Seven heavens: that is, air, aether, Olympus, fire, the Firmament, the heaven of the angels, and the heaven of the Trinity. *Bede.* Or: the lowest and the highest region of the air, the lowest and the highest of fire; the starry, the crystalline, the Empyrean. *Rabanus.*	8
VIII.	Eight starry heavens: namely the Aplanes, or sphere of the fixed stars, and the 7 spheres of the planets. *The Babylonians, the Egyptians, Eudoxus, Plato, Callippus, Aristotle, Cicero, Philo; Saints Basil, Ambrose, Damascene, Bonaventure, Remigius, Thomas; also Avenezra [Ibn Ezra], Carthusianus, Lyranus, Tostatus, Burgensis, Riccius, Orontius, Cremoninus, Philalthaeus, Amicus, Ruvius.* Of these, however, Augustinus Riccius, Orontius and Amicus attribute a proper motion to the eighth sphere.	9
	Nine heavens: namely the Empyrean and eight starry heavens, if the starry ones are solid. *Arriaga.*	10
IX.	Nine heavens: that is, the primum mobile and eight starry heavens. *Macrobius, Haly, Alpetragius, Rabbi Iosue, Rabbi Moyses, Scotus, Abraham Zagutus [Avraham Zacuto], Sacrobosco, Chiaramonti*; it is attributed by many to *Hipparchus* and *Ptolemy*, but not safely enough.	10
	Ten heavens: namely the primum mobile; a sphere for the motion of the fixed stars and of the auges; the eighth sphere, for the trepidation in longitude; and seven planetary spheres. *The Alphonsines, Fernelius, Purbachius, Regiomontanus, Giovanni Battista Amico, Apian, Maurolico, Langius.*	11
X.	Ten heavens: that is, the primum mobile; a sphere of trepidation in longitude; a sphere of the fixed stars; and seven planetary spheres. *Arzachel, Thebit, Isaac Israelita [Isaac Israeli].*	11
	Ten heavens: namely the Empyrean, the primum mobile, and eight starry heavens. *Gulielmus Parisiensis and Io. Antonius Delphinus.*	11
	Eleven heavens: namely the Empyrean and the ten mobile spheres of the Alphonsines. *Petrus Alliacensis, the Conimbricenses, Martinengus*, and formerly *Clavius*.	12
XI.	Eleven heavens: namely the primum mobile; a sphere of the first libration, in latitude; a sphere of the second libration, in longitude; a sphere of the fixed stars; and seven spheres of the planets. *Io. Vernerus [Johannes Werner], Leopoldus de Austria [Leopold of Austria], Giovanni Antonio Magini*, and later *Clavius* — though for him, since he admits the Empyrean, the heavens come to 12.	12
XII.		
XIV.	Fourteen: *Giovanni Battista della Torre and Fracastoro*; on them see what we shall say below, in the Fracastorian system.	

CAPVT II.

Chapter II.

Quid & Quotuplex ſit Syſtema Mundi. Et de Syſtematibus vetuſtiſſimis, ac præcipuè de Pythagoræ, Archimedis, & Plinij, quod Ptolemaicum dici ſolet; viguitq. vſq. ad Clauium.

What the system of the world is, and of how many kinds; and on the most ancient systems, and chiefly on those of Pythagoras, of Archimedes and of Pliny — the last usually called the Ptolemaic, which prevailed down to Clavius.

[Margin: What a system is.]

I. The system of the world is nothing other than the co-ordination, or composition, of the great parts of the world — namely of the elements and of the heavens. Its matter, as it were, is the number of the elements and of the heavens, both total and partial; its form is their order and position with respect to one another and relative to the centre of the universe. Considered by its form, therefore, the system of the world is divided into two highest genera: the one constructed around the Earth, immobile at the centre of the universe; and the other constructed around the Sun, immobile at the centre of the universe — that is, free from τῆς φορᾶς κατὰ τόπον [Greek: tēs phoras kata topon, "motion from place to place"], namely from translation — while moving the Earth through an annual orb.

[Margin: How many kinds of system there are.]

Again, each of the two, but chiefly the first, is subdivided into the homocentric, the eccentric, and the mixed, made up of some orbs concentric and some eccentric. Now, since enough was done in the preceding chapter on the number of the heavens, as the remote matter of the cosmic system, it follows that we should treat of the order of the heavens and the planets, and of the number of the partial orbs. And we take our beginning from the most ancient.

[Margin: The alternating rise and fall of systems.]

II. It is, moreover, most worthy of observation that two sects of physicists and mathematicians have, like Castors and Polluxes, alternately died away and then, revived, prevailed once more in the schools. For first Pythagoras, with some of his sect[28], placing the Earth at the centre of the world, used eccentrics and epicycles and placed the Sun in the middle of the planets. Others of the Pythagoreans, however, keeping the epicycles and eccentrics, nevertheless placed the Sun at the centre of the world, and the Earth in the middle of the seven planets. Then Plato restored the Earth again to the centre of the universe, and placed the Sun in the middle of the planets — in such a way, however, that he thought Venus and Mercury were for the most part carried above it. Following him, Eudoxus, Callippus and Aristotle tried to explain the whole motion of the planets by concentric circles; and so they held that neither Venus nor Mercury goes above and below the Sun on epicycles, but that they are either always above the Sun or always below it. When these had gone the way of fate, others again embraced eccentrics and epicycles, with the Earth in the

[28]the page prints "rectę", for "sectę"

middle of the world — such as Archimedes, Hipparchus, Sosigenes, Cicero, Vitruvius, Pliny, Macrobius and Capella, though with a varying order of the planets. Others, who moved the Earth from its place, such as the Pythagoreans Aristarchus and Philolaus, either did not set out what they thought about eccentrics and epicycles, or it has not been handed down to posterity. Ptolemy, again, reviving the most ancient opinion of the Pythagoreans, so established eccentrics and epicycles that he kept the Earth in the middle of the world and the Sun in the middle of the planets; and by persuading the greatest part of astronomers of this opinion he extended it down to the fourteenth century. That order of the planets, however, Alpetragius and Geber judged should be changed. But Alpetragius, Amicus and Delphinus, with a few others, also took up homocentrics again; by contrast, Turrianus and Fracastoro, keeping the Ptolemaic order, nevertheless brought homocentrics back to light — and indeed more of them than Aristotle's, let alone Eudoxus's. About the same time, moreover, Copernicus not only called up from the tombs the fiction of Philolaus and Aristarchus about an annual motion of the Earth around an immobile Sun, but adorned it with arguments so plausible that he has persuaded very many of it down to this day; Venus and Mercury, however, he carried round now below, now above the Sun, with Plato, Vitruvius, Macrobius, Capella and Bede. From this Tycho, and Longomontanus with him, having found a most beautiful handle, not only bade Venus and Mercury, but Mars too, and Jupiter and Saturn, go round the Sun, and the Sun and the Moon, with the fixed stars, round the Earth, which rests in the middle of the world free from all motion of translation; and, keeping the eccentrics, he did away with the Ptolemaic epicycles. Finally Argoli, dislocating the Tychonic system, tried to make the three superior planets move around the Earth, but Mercury and Venus around the Sun, the Earth being left in the middle of the world. We, for our part, judge that Saturn and Jupiter, the Sun, the Moon and the fixed stars can be arranged around the Earth, but Venus, Mercury and Mars around the Sun. Lastly, Signor Giovanni Battista Baliani suspected that the Moon could be placed at the centre of the world. It is worth the effort, then, to discuss one by one so many and such diverse attempts and endeavours, and to weigh the reasons brought forward on either side.

[Margin: Ancient but absurd systems.]

I have, however, passed over as of no consideration those three opinions which Plutarch sets out in Book 2 of *De placitis*, chapter 15, in this way: *Xenocrates thinks that the stars move on one and the same surface. The other Stoics, at heights and depths that vary among themselves. Democritus puts the fixed stars highest, then the wandering stars, and below these the Sun, Lucifer, the Moon, etc. Metrodorus of Chios and Crates set the Sun highest of all, after it the Moon, and below these the wandering and the unwandering stars.* So true is it that nothing is absurd that does not fortify itself with some patron.

[Margin: The system of Pythagoras.]

III. The most ancient of the tolerable systems, then, was the Pythagorean. In it Pythagoras arranged the intervals by harmonic ratios in such a way that, starting from the Earth, he ascended from there to the Moon, then to Mercury, then to Venus; then on to the Sun, and from the Sun to Mars, then to Jupiter, then to Saturn, and finally from Saturn to the fixed stars — as Pliny relates expressly in Book 2, chapter 22. For he says: *Pythagoras sometimes, on a musical reckoning, calls the distance of the Moon from the Earth a tone; from her to Mercury, half of that space, and from him to Venus about the same; from her to the Sun, one and a half times as much; from the Sun to Mars, a tone, that is, as much as from the Earth to the Moon; from him to Jupiter, a half, and from him to Saturn, a half; and from there, one and a half to the zodiac [Signifer].* With this Censorinus agrees entirely, in his book *De die natali*, chapter 11, near the end, in these words: *Pythagoras therefore thought that from the Earth to the Moon there are about 126,000 stadia, and that this is the interval of a tone; from the Moon to the star of Mercury, which is called* στίλβων *[Greek: stilbōn, "the Glittering"], half of that, as it were a* ἡμιτόνιον *[Greek: hēmitonion, "semitone"]; from there to* φόσφορον *[Greek: phosphoron, "Light-bringer"], which is the star of Venus, about the same, that is, another semitone; then on to the Sun three times as much, as it were a tone and a half; and so the star of the Sun is three tones and a half from the Earth, which is called the diapente; and from the Moon two and a half, which is called the diatessaron. From the Sun to the star of Mars, whose name is* πύροεις *[Greek: pyroeis, "the Fiery"], there is as much interval as from the Earth to the Moon, and this makes a* τόνον *[Greek: tonon, "tone"]; from there to the star of Jupiter, which is called* φαέθον *[Greek: phaethon, "the Shining"], half of that, which makes a semitone; from there to the highest heaven, where the signs are, likewise a semitone.*

[Margin: The Pythagoreans the originators of eccentrics and epicycles.]

So much for the order and symmetry of the heavens according to Pythagoras. That the Pythagoreans first devised eccentrics and epicycles, Nicomachus is the authority, in *Simplicius*'s commentary on Book 2 of *De caelo*, where he carefully sets out the hypotheses of the ancients; and, following him, *Giovanni Battista Amico* (*De motibus corporum caelestium*, chapter 6), and *Io. Antonius Delphinus* (*De caelestibus globis et motibus*, chapter 4), where he attributes this very thing to Pythagoras.

[Margin: The system of Pythagoras not received by all the Pythagoreans.]

From what has been said it is clear that Paulus Antonius Foscarinus [Paolo Antonio Foscarini] is not right to call "the system of Pythagoras", or simply "the Pythagorean", the one in which the Sun is at the centre of the world and the Earth revolves around the Sun above Mercury and Venus — granted that some disciples of Pythagoras held so.

[Margin: The system of Archimedes.]

IV. Archimedes subscribed to the Pythagorean system as regards the order, if what *Macrobius* relates of him (Book 2 on the *Dream of Scipio*, chapter 3) is true: *And Archimedes believed he had found the number of stadia by which the Moon is distant from the surface of the Earth, Mercury from the Moon, Venus from Mercury,*

the Sun from Venus, Mars from the Sun, Jupiter from Mars, and Saturn from Jupiter. He also thought he had measured by reasoning the whole space from the orb of Saturn up to the starry heaven itself. This dissent of Archimedes, however, was rejected by the Platonists.

[Margin: And of Cicero.]

And not Archimedes only, but Cicero too, in the *Dream of Scipio* — whose words we shall report in a more suitable place, in the following chapter, number 4, so as to separate him from Plato.

[Margin: The system of Pliny.]

V. *Pliny* himself also, in Book 2, chapters 5, 6, 8, 15, 16 and 17 taken together, expressed the same order, and acknowledged the apsides of the eccentrics and epicycles, that is, the perigees and apogees of the planets — doubtless from Sosigenes, from whom he was accustomed to draw much. So in chapter 5 he says: *that the Earth is lowest and in the middle of the whole, and that it stands suspended at the pivot of the universe, balancing the things by which it is suspended; and so that it alone is immobile, with the universe revolving around it.* Then chapter 6: *Between it and the heaven, suspended in the same air, hang seven stars separated by fixed intervals, which from their gait we call wandering, though none wander less than they; in the middle of them the Sun is carried.* But with greater distinction, chapter 8: *Now, leaving the body of the world itself, let the rest, between the heaven and the Earth, be treated. It is certain that the highest is the star they call Saturn's, and that for this reason it appears smallest, goes round in the greatest circle, and returns in the thirtieth year to the shortest beginnings of its seat, etc. The star of Saturn is of a cold and stiffening nature; and the circle of Jupiter, much below it, is for that reason carried round with a swifter motion in twelve years. The third, that of Mars, which some call Hercules's, fiery and burning from the nearness of the Sun, turns round in about two years; and so, from the excessive heat of this one and the cold of Saturn, Jupiter, set between the two, is tempered by both and becomes beneficent. Next, the course of the Sun is of 360 degrees; but, so that the observation of its shadows may return to its marks, five days are added to the years, and above that a fourth part of a day. For this reason one intercalary day is added in the fifth year, so that the reckoning of the times may agree with the Sun's journey. Below the Sun goes round a great star called Venus's, wandering with an alternating course, and in its very surnames a rival of the Sun and the Moon. For when it goes before and rises ahead of the morning, it takes the name of Lucifer, as a second Sun hastening the day; when, on the contrary, it shines out from the west, it is named Vesper, as prolonging the light and taking the Moon's turn. This nature of it Pythagoras of Samos first detected, about the forty-second Olympiad, etc. It completes the circuit of the zodiac in 348 days, never standing off from the Sun by more than 46 degrees, as Timaeus holds. In a similar way, but by no means next to it in size, the star of Mercury, called by some Apollo's, is carried in a lower circle, in a circuit nine days quicker, shining now before sunrise, now after sunset, never more than 23 degrees distant from the Sun, as this same author and Sosigenes teach, etc.* From here he goes on in chapter 9 to speak of the Moon, and from chapter 15 to 17 he treats of the stations and regressions, the elevations and depressions,

the speed and slowness of the planets, and refers their causes to the position of the circles, according as they approach their apsides or recede from them.

[Margin: Pliny accepts eccentrics.]

Let these words of chapter 15 be noted: *All these things happen for several causes. The first is that of the circles which the Greeks call apsides in the stars — for we shall have to use Greek words. Each of them has its own, and these are other than those of the world;* [?] and a little later: *Therefore the apsides of each rise from a different centre, and for that reason they have different orbs and unlike motions, etc.* Do you see how Pliny has marked out eccentric orbs?

[Margin: The system of Ptolemy.]

VI. As Pliny was growing old, *Ptolemy* began to flourish. He willingly took up the system of Pythagoras, which he knew had certainly pleased Archimedes, Hipparchus and Sosigenes, and fortified it with several arguments: both as regards the eccentrics and epicycles, which he used in Books 3, 4 and 5, and from 9 to 13, of the *Almagest*; and as regards the order of the planets and the position of the immobile Earth at the centre of the universe. His arguments on the position and immobility of the Earth, from Book 1 of the *Almagest*, chapters 5 and 7, although we did not neglect them in Book 2, chapters 2 and 3, will nevertheless have to be treated more carefully below, in section 4, and weighed together with the solutions of the Copernicans. As regards the order of the planets, here are his own words from Book 9 of the *Great Construction*, chapter 1: *The sphere of Saturn, which is the greater, and that of Jupiter, which is second and nearer the Earth, and that of Mars beneath it, are more remote from the Earth than the rest. That of the Sun, too, is described in almost the same way by all the first mathematicians. The spheres of Venus and Mercury, however, are placed by the ancients below the solar sphere; but by some of the more recent they too are, for this reason, placed above it: because the Sun has never been seen to suffer eclipse from these planets. But this reasoning seems weak to us. For some planets can be below the Sun and yet not be set against it, because they are not in the same plane passing through them and our sight — just as in the conjunctions of the Moon, for the most part, no failure of the Sun occurs. But since an understanding of this matter cannot be had otherwise, because none of these stars makes a sensible parallax, from which alone distances are taken, the order of the ancients seems to me plausibly to proceed more naturally, since, with the Sun placed in the middle, it separates those planets which can digress from the Sun by any distance whatever from those which cannot so digress but are always carried round close to it — although it does not remove them so far from the Sun towards the Earth that a parallax worth taking into account can arise.*

[Margin: Ptolemy's reasoning defended against the objections of Geber and Copernicus.]

With these words he certainly forestalled well enough the objections that were later to be hurled against him by Geber and Copernicus. For he does not deny Venus and Mercury all parallax, since by the very fact that he places them below the Sun he is compelled to grant them a somewhat greater one than the Sun's — to Venus at perigee about 3′, and to Mercury 7′, as *Geber* gathers

in Book 7, chapter 1, of his *Astronomy*. What he denies is that this parallax needs to be taken into account in this business, or that it is so evident from observations that their distance could be established from it, known in advance. Besides, he does not deny absolutely that some very small part of the Sun can be eclipsed by Venus or Mercury — for Geber shows in the same place that this follows from the Ptolemaic hypothesis — but he says that, if this has not been observed, it happened because the observations of the conjunctions of the Sun with Venus or Mercury were made at a time when either of them, on account of its latitude from the ecliptic, appeared on this side of or beyond the Sun's disc. Finally, both Geber, above, and *Copernicus*, Book 1, chapter 10, argue thus: *That argument of Ptolemy's too* — the words are Copernicus's — *that the Sun must be carried in the middle, between the planets that digress from it in every way and those that do not, is shown to be unpersuasive by the fact that the Moon, which also digresses in every way, betrays its falsity.* But Ptolemy thought this argument plausible not absolutely, but on the supposition that knowledge of this matter cannot be had otherwise; whereas the Moon's place below the Sun is manifest from elsewhere, both from eclipses and from the lunar parallaxes, which very evidently exceed the solar ones.

[Margin: The system of Regiomontanus.]

VII. To Ptolemy, moreover, as regards the order of the planets, there subscribed in turn all the Arabs, except Geber and Alpetragius; all the Greeks, except Theon; and finally all the Latins down to Clavius, before the use of the telescope had taken hold — with the exception of Martianus Capella, Macrobius, Apuleius, Sammerius, Bede, Copernicus and the Copernicans; but chiefly *Ioannes Regiomontanus* [Regiomontanus], in the *Epitome of the Almagest*, Book 9, proposition 1. He kept Venus and Mercury below the Sun all the more willingly because he thought it the more likely that the space between the Sun at perigee and the Moon at perigee — namely of 1006 terrestrial semidiameters, as he himself computes — ought not to be empty of every star. He adds, and so do *Clavius* (in the *Sphere*, page 71) and the *Conimbricenses* College (on Book 2 *De caelo*, chapter 7, question 4, article 2), that the eclipse the Sun suffers from Venus passing beneath the Sun's disc is not sensible, because the disc of Venus is about a hundredth part of the Sun's disc, as I too computed in Book 7, section 1, chapter 4, number 4; and that the eclipse by the tiny Mercury is much less so — or, as *Copernicus* puts it (Book 1, chapter 10): *so small a spot is not easily seen under the most excellent light.*

[Margin: Regiomontanus defended against the attacks of Copernicus.]

But these things, as I said in the same place, are to be understood of the naked eye, and before or apart from the use of the telescope; otherwise, I related in Book 3, chapter 3, scholium 3, that Mercury has been seen beneath the Sun with the help of the telescope; and there, in scholium 2, I also showed that the blackish thing seen beneath the Sun by Averroes, or Avenrodan, or by others in the time of Charlemagne, was not Mercury but one or more spots of the Sun. But *Copernicus* (Book 1, chapter 10) refutes the first reason of Regiomontanus —

whom, however, whether from forgetfulness or from swollen pride, he passed over unnamed — on the ground that between the Moon and us there are air and fire, and a space of 52 semidiameters empty of every star. Regiomontanus, however, would reply that the case is not alike, because air and fire are not heavens, nor a place fit to contain a star. Copernicus adds that the semidiameter of the epicycle of Venus, by which she digresses from the Sun about 45 degrees on either side, occupies a greater space than there is from the Earth to Mercury at apogee, and yet is empty of any star; but Regiomontanus would reply that the space within that epicycle is not empty, since Venus runs through it from apogee to perigee.

[Margin: The system of Clavius.]

VIII. Finally our *Clavius* tried to confirm the order of the Pythagorean and Ptolemaic system in chapter 1 of the *Sphere*, from page 65 in my copy, and from him *Franciscus Barocius* [Francesco Barozzi], Book 1 of the *Cosmographia*, page 9. These reasons must be weighed.

[Margin: Clavius's first reason, from parallax.]

The *first* is from parallax: for the greater it is, other things being equal, the nearer to the Earth is the star that has it, as is clear from what was said in Book 1, chapter 35; but the parallax of the Moon is far greater than that of the Sun, as is plainly established from what was said in Book 3, chapter 8, and Book 4, chapter 14; likewise the parallax of Mercury is greater than that of Venus, and that of Venus than that of the Sun, says Clavius — for he admits that this argument does not tell for the three superior planets. But in truth, as Regiomontanus admits (Book 9 of the *Epitome*, proposition 1), and before him Ptolemy (Book 9 of the *Almagest*, chapter 1), the motion of Venus and Mercury is not known so scrupulously that their parallax can be discerned evidently from it, especially when using the Ptolemaic or Alphonsine tables; rather, their distance from the Earth must be established from elsewhere, and the parallax then gathered from it by reasoning. Further, since it is now established, the telescope showing it, that Venus and Mercury, when they are nearer the apogee, move above the Sun, it is false that their parallax is then greater than the Sun's. Again, since they go round the Sun in such a way that Mercury digresses less from the Sun, it follows that Mercury at its perigee is higher than Venus at perigee, and so undergoes a smaller parallax.

[Margin: Second reason, from shadows.]

The *second* reason is drawn from the shadow: for the smaller the shadow of a gnomon, the higher (other things being equal) is the star by whose rays, carried through the tip of the gnomon, the shadow is cast, as is clear from the diagram brought in at Book 4, chapter 10, number 1. But at an equal elevation above the horizon the solar shadow is shorter than the lunar; indeed, says Barocius, the shadow of a ray of the Sun is shorter than that of a ray of Venus, Venus's than Mercury's, and Mercury's than the Moon's; and he testifies that this has been proved by experience. For the rest, we grant this of Venus at perigee with respect to the Sun, but deny it of her with respect to Mercury; and of either

planet when it is near the apogee we likewise deny it — quite apart from the fact that the experiment of Mercury's shadow is suspect to me, since Mercury near perigee usually lies hidden under the glare of the Sun, and even at its greatest digression does not appear without the twilight washing out its shadows.

[Margin: Clavius's slip.]

This argument could certainly have been applied much more clearly to Jupiter, whose shadow is more evident than Mercury's. And so I could wish that these words had not escaped Clavius (page 68 of the *Sphere*): *What we have said of the Moon with respect to the Sun can be applied with respect to the other planets; for although the other planets do not shine so as to cast a shadow, it can nevertheless be known how far their rays are cast through the tips of gnomons.* For the rays of Venus and Jupiter do cast a manifest shadow. Then, how slippery is that application and supplementing of the shadow! — namely by placing the eye in the plane and looking back at the planet through the tip of the gnomon; and how difficult it is, in these planets, to know in advance the moment at which they stand at such and so great an altitude above the astronomical horizon, independently of their distance from the centre of the Earth. But it is all too easy to invent experiments from a presupposed hypothesis, and to suppose that experiments never made would turn out so, if they were made.

[Margin: Third reason, from eclipses.]

The *third* reason is sought from mutual eclipses: for that star is nearer to the Earth, and to us observing from the Earth, which by the interposition of its body hides the other from us; but the Moon hides from us not only the Sun but all the other planets; therefore the Moon is the lowest of all. *By the same reasoning Mercury will be below Venus, and Venus below Mars, and so on*, says Clavius — that is, from the presumption of this system, not from any experiment concerning Mercury; for Mercury has never been seen to have hidden Venus; indeed perhaps it has never even been able to hide her, nor will be, but rather Venus Mercury. See what we set out about these occultations of the planets, established from observation, in Book 5, chapter 2, scholium 2, and Book 7, section 6, chapter 14.

[Margin: Fourth reason, from the swiftness of motion.]

The *fourth* reason is taken from the speed of the proper motion and the slowness of the common motion: for the farther a planet is from the primum mobile and from the fixed stars, the more quickly it completes its period, tending eastward; and so it comes about that, returning daily later to the same meridian, it appears slower than the motion of the primum mobile and of the fixed stars towards the west. Since, therefore, the fixed stars cannot complete their period except after many thousands of years, while Saturn completes it in about 30 years, Jupiter in 12, Mars in about 2 years, the Sun in a single year, and the Moon within one month, and Venus and Mercury complete it more quickly than Mars and more slowly than the Moon, it is established that below the fixed stars there stands, immediately, Saturn; below him Jupiter; below Jupiter, Mars; below Mars, the Sun, Venus and Mercury; and below these, finally, the

Moon. From this argument, however, Clavius denies that anything certain can be gathered about the order of the Sun, Venus and Mercury among themselves: for the mean motions of the Sun, Venus and Mercury are equal, while the apparent motion on the epicycle lasts longer for Venus than for the Sun, and for the Sun than for Mercury. By this argument Alpetragius, as we shall relate below, contends that Venus must be placed below Mars and above the Sun, and Mercury below the Sun. Further, as we said in Book 7, section 3, chapter 11, towards the end, the revolution of Venus, reckoned with the motion of the Sun which she accompanies, is of very nearly 584 days, and that of Mercury of about 116; but about a Sun at rest the revolution of Venus is of about 225 days, and that of Mercury of about 88.

[Margin: 5. Reason from the interval between the Sun and the Moon not being empty.]

The *fifth* reason is the one I have already brought forward from Regiomontanus in number 6: namely, that the space from the Moon to the Sun should not be empty of a star. This reason tells much more strongly in the hypothesis of Kepler, in ours and in that of Vendelinus [Wendelen], in which many more semidiameters of the Earth than 1006 intervene between the Moon and the Sun: for Kepler there are about 3400, for me 6036, for Wendelen about 14,600. In the Ptolemaic system, moreover, the intervals of the planets are so ordered that nothing superfluous intervenes between heaven and heaven, but the lowest part of Saturn, or its perigee, touches Jupiter at apogee, and so of the rest, as we taught in Book 7, section 6, from chapter 1 to 4. But this reason now ceases in the more recent hypothesis. In that hypothesis, if, as the telescope shows, we carry Venus round the Sun in a wider circuit and Mercury in a narrower one, and wish to keep intact the magnitude of the epicycle of Venus derived from her greatest digressions from the Sun and from the Sun's distance from the Earth, then a great space must intervene between the Moon at apogee and Venus at perigee, empty of every ordinary planet. This may be seen by anyone who compares the lunar distances (on which see Book 4, chapter 14) with the least distances of Venus from the Earth on the more recent hypotheses (on which see Book 7, section 6, chapter 2, in table 2).

[Margin: 6. Reason from the multiplicity of motions.]

The *sixth* reason is taken from the multiplicity and irregularity of the motions: for Mercury has more motions than Venus and the Sun, and therefore the Ptolemaics assign Mercury five orbs and an epicycle, but Venus three. But this reason is very weak, for on that ground the Sun would have to be placed above all the planets, because in the simplicity of its motion it is more like the motion of the fixed stars and of the primum mobile than all the planets are. For this reason Aristotle said, in Book 2 *De caelo*, chapter 10, or text 60: *It is no less a marvel for what cause those bodies which are farther from the first motion are not always moved with more motions, etc. For the Sun and the Moon are moved with fewer motions than some of the wandering stars, although these are farther from the centre, and nearer the first of the bodies, than they are.* And yet the latest age has

detected many more motions in the Moon, according to what was said in Book 4, chapter 18. Clavius could therefore have neglected this paltry little reason.

[Margin: 7. Reason from the dependence of the planets on the Sun.]

The *seventh* reason is drawn from the dependence of the planets on the Sun in light and motion. For the Sun is like the King and Heart, the rule and moderator of all the planets, since all the planets are bound in their motions to the motion of the Sun by a certain admirable harmony: this is established for the synodic revolutions of the Moon, and for the periods of the other planets, whether on the eccentric or on the epicycle, it is clear from what was said in Book 7, section 1, chapter 7. The Sun therefore ought to proceed in their midst, so as to direct their motions evenly and to illuminate them, since we see Mars and Venus more strongly illuminated because of their nearness to the Sun. Nor did Clavius refrain from the likeness and analogy of the things customary in human polities, so as to set the Sun in the middle place as a King. For he says that Saturn, being an old man, is the Sun's counsellor; Jupiter, for his magnanimity, the judge; Mars the general of the army; Venus the mother of the household; Mercury the scribe or chancellor; and the Moon, finally, the swiftest messenger — *as most people jest*, says Clavius, for he did not wish these things to be recounted by himself in earnest; granted that Stœflerus [Johannes Stöffler], on Proclus, page 44, relates them in earnest. But these things are said too much in the manner of commonplaces; and by almost the same argument the Copernicans contend that the Sun ought to have been placed in the middle of the whole universe, and Tycho in the middle of the five lesser planets that surround it. Nor must a King or Master or Leader always be in the middle of his people; often he follows behind them all, or sometimes even goes before them.

[Margin: 8. Reason from the activity of the Sun.]

The *eighth* reason, which *Albumasar* [Abū Maʿshar] brings forward in his *Great Introduction*, tractate 3, difference 3, rests on the Sun's activity: for it ought to be placed in the middle of the planets, lest, if it were higher, it should act too little on these lower things, and, if lower, too much. Hence Clavius thinks that Ovid too alluded to this in *Metamorphoses* 2, where he brings in Phoebus guiding with his counsel Phaethon as he drives the solar four-horse chariot:

Going too high, you will burn the signs of heaven; too low, the earth; in the middle you will go most safely.

But if this reason held, the Sun would have to be in the middle of the interval from the Earth to the fixed stars, precisely as to quantity; whereas in no hypothesis, much less in the Ptolemaic, can this be true, as is established from the distances of the planets from the Earth reduced by us into a table in Book 7, section 6, chapter 2.

[Margin: 9. Reason from the days of the week and the dominion of the planets.]

The *ninth* reason is taken from the order and naming of the seven days of the week. Xiphilinus, from Book 36 of Dio [Cassius Dio], in the *Pompey*, reports

that this order was established by the Egyptians: beginning from Saturn and assigning him the dominion of the first hour of the day, and running through the 24 hours in this order of the planets, ♄ ♃ ♂ ☉ ♀ ☿ ☾, the dominion of the first hour of the following day falls on the Sun, of the next on the Moon, then on Mars, afterwards on Mercury, then on Jupiter, and finally on Venus, according to what was said more fully in Book 1, chapter 30. But Dio in the same place, and Xiphilinus, indicate another reason too for this order, taken from the harmonic intervals, which Pliny the Elder and Censorinus, brought forward in number 3, also intimated to us from Pythagoras. And that distribution presupposes the order of the days already mentioned, but does not produce it; for it is not true — indeed it is a most empty fiction — that the Sun rules the first hour of the Lord's day more than any other planet, and so of the rest. The rest concerning the harmonic intervals, which each man tries to draw over to his own system, is to be discussed in section 5 of this book.

For these reasons, then, and chiefly because of its antiquity and authority, this system prevailed over all the others from Pythagoras right down to our own age; and so for about 20 centuries it had on its side the greater part of the astronomers, and many of the theologians and natural philosophers. It is pleasing to review the chief of them.

Auctores qui Pythagoræ & Ptolemæo ſubſcripſere quoad Ordinem Planetarum.

Authors who subscribed to Pythagoras and Ptolemy as regards the order of the planets.

IX. I said "as regards the order": for as regards the number of the heavens, total or partial, some disagreed, as is clear from what was said here in chapter 1; and as regards the hypothesis of eccentrics, the homocentrists disagreed, as we have already said in section 2, chapter 2. But as regards the order of the planets, this system was favoured by *Archimedes* (in Macrobius, Book 2 on the *Dream of Scipio*, chapter 3); the *Chaldaeans* (in Bede, in the book *De elementis philosophiae*); *Cicero* (*On the Dream of Scipio*); *Pliny the Elder* (Book 2, chapters 6 and 7); *Cleomedes* (Book 1 of the *Cyclical Theory*, chapter 3); *Sosigenes* (in Simplicius, on Book 2 *De caelo*); *Albategnius* [al-Battānī] (*De scientia stellarum*, chapter 50); *Alfraganus* (difference 12, where he says he follows the opinion of the ancients); and *Albumasar* (in his *Introduction*, tractate 3, difference 3). These were followed by the greater part of the Arabs, and by the Alphonsines in their tables; by *Io. Fernelius* (Book 1 of the *Cosmotheoria*); by *Purbachius* in the *Theoricae planetarum*, and by his commentators, chiefly *Petrus Nonius* [Pedro Nunes], *Erasmus Reinholdus* [Erasmus Reinhold], *Erasmus Osualdus* and *Christianus Vurstisius* [Christian Wurstisen]. Besides these: *Regiomontanus* (in the *Epitome of the Almagest*, Book 4, proposition 1); *Io. Stoeflerus* (on Proclus's *Sphere*, page 44); *Iulius Firmicus* [Firmicus Maternus] (Book 3 of the *Mathesis*, from chapter 3 to 9); *Iovianus Pontanus* [Giovanni Pontano] (Book 7 *De rebus caelestibus*); *Io. de Sacrobosco* [Johannes de Sacrobosco] (chapter

1 of the *Sphere*), and there his interpreters, enumerated at the beginning of Book 1 of our *Almagest*; *Orontius* (in the *Sphere*, Book 1, chapter 3); *Io. Baptista Amicus* (the little work *De motibus corporum caelestium*); *Io. Antonius Delphinus* (*De globis caelestibus*); *Fracastorius* [Girolamo Fracastoro] (in the *Homocentrica*, sections 2 and 3); *Egnatius Dantes* [Egnazio Danti] (in the tables, from table 12); *Petrus Apianus* [Peter Apian] (in the *Astronomicum Caesareum*); *Gemma Phrysius* [Gemma Frisius] (*De principiis cosmographiae*, chapter 1); *Maurolycus* [Maurolico] (dialogues 1 and 3 of the *Cosmographia*, and at the end of the same); *Io. Antonius Maginus* (in the *Theoricae planetarum*); *Clavius* (on the *Sphere*, from page 64); *Barocius* in the *Cosmographia*, Book 1, page 8; *Rodulphus Goclenius* [Rudolph Goclenius] in the *Uranie*, chapter 4; *Michaël Neander* [Michael Neander] in the *Elementa doctrinae sphaericae*, chapter 4; *Cardanus* [Girolamo Cardano], *De varietate*, Book 1, chapter 1; *Ascanius Martinengus* in the *Glossa magna*, page 968. Finally, to add one or two Fathers: *St Damascene*, in Book 2 *De fide orthodoxa*, chapter 7, supposes that *in the first circle of the heaven, that is the highest, is Saturn; in the second Jupiter; in the third Mars; in the fourth the Sun; in the fifth Venus; in the sixth Mercury; and in the seventh and lowest the Moon.* And Bede, following Pliny, set out the same order in the book *De natura rerum*, chapter 13, and in *De ratione temporum*, chapter 24 — although in Book 2 of *De elementis philosophiae* he teaches that Venus and Mercury go round the Sun.

If anyone wants a figure, though it is not necessary, of the system of Pythagoras[29] and Ptolemy etc. — which may be called the common and most ancient system, and the Chaldaean or Babylonian, as we shall learn from Bede in chapter 4, number 4 — here it is; in it, however, the eccentrics and epicycles are to be understood, according to the diagrams given in Book 7, sections 2 and 3.

Diagram. *I. The most ancient and common system, of Pythagoras, Ptolemy and very many others.* A woodcut in the left column: an outer band, between two circles and divided by radial strokes, carries the twelve signs of the zodiac; small star marks stand in the band next inside it and between the circles; within, a series of concentric circles, with the planetary signs set one above another on a vertical line from the top downward; at the centre, a small disc with a figured interior, ringed by small star-like marks.

- Outer band, clockwise from the top: ♋ (upper left of the top), ♊ (top), ♉ (upper right), ♈ (right), ♓ (lower right), ♒ (lower right), ♑ (bottom right), ♐ (bottom), ♏ (lower left), ♎ (left), ♍ (left), ♌ (upper left) — the signs of the zodiac
- Vertical line, from the top: ♄ Saturn, ♃ Jupiter, ♂ Mars, ☉ the Sun, ♀ Venus, ☿ Mercury, ☾ the Moon
- Centre: an unlabelled disc with a figured interior

[Margin: Clavius's last word on the system, once the telescope had been seen.]

[29] the page prints "Pythagotæ"

X. Thus far the astronomers down to Clavius, as long as the heaven was explored with unarmed eyes. But when the Belgian telescope had been brought to Rome, and Venus had been seen to be illuminated by the Sun like the Moon, in such a way that she must go round it, and other things like these, the good and candid old man Clavius exclaimed — indeed, like a swan near death, he sang of the change of the ancient system in these words, which Scheinerus [Christoph Scheiner] (number 22 of the *Disquisitiones mathematicae*) and Tannerus (*De caelo*, question 10) quote from the last edition, on chapter 1 of the *Sphere*, page 75: *I do not wish, however, this to be hidden from the reader: that not long ago a certain instrument was brought from Belgium, like a kind of oblong tube, in whose ends two glasses, or lenses, are fitted, by which objects far removed from us appear very near, and indeed far larger than they are in reality. With this instrument very many stars are discerned in the firmament which can in no way be seen without it, etc. The Moon too, when it is horned or half full, appears in a wonderful way broken and rough, so that one cannot marvel enough that such great inequalities are present in the lunar body. But on this matter consult the little book of Galileo Galilei which he entitled* Sidereus Nuncius, *printed at Venice in the year 1610. Among the other things seen with this instrument, this holds not the last place: namely, that Venus receives her light from the Sun, like the Moon, so that, horned, she appears now more, now less, according to her distance from the Sun — which I have observed here at Rome, with others, more than once.*

[Margin: Galileo praised by Clavius.]

Saturn too has two stars joined to it, smaller than itself, one towards the east and the other towards the west. Jupiter, finally, has four wandering stars, which vary their position in a wonderful way, both among themselves and with respect to Jupiter, as Galileo diligently and accurately describes. SINCE these things are so, let the astronomers consider in what way the celestial orbs must be constituted so that these phenomena can be saved. Thus Clavius. But let us proceed to the other systems.

CAPVT III.

Chapter 3.

De Syſtemate Platonis, Platonicorum, Gebri, ac Theonis. Qua occaſione diſputatur de Ciceronis Syſtemate.

On the system of Plato, of the Platonists, of Geber and of Theon. On which occasion the system of Cicero is discussed.

I. Just as discord not seldom brings forth concord, so concord has brought forth discord. For there was a wonderful concord between Pythagoras and Plato on this point: that the intervals and order of the planets were to be established from the laws of music. But at once discord was born from this, through the differing opinions on the harmonic interval [diastema] among the Platonists and the Pythagoreans. Nor do all write alike even about the Platonic system itself. For Plutarch — certainly most learned in Greek matters — in Book 2 *De*

placitis philosophorum, chapter 15, after relating the opinions on the order of the stars (on which I spoke in chapter 2, at the end of number 2), continues thus: *Plato, after the position of the fixed stars, puts first Phaenon, which is called Saturn's; second Phaethon, which is Jupiter's; third Pyroeis, which is Mars's; fourth Phosphoros, which is Venus's; fifth Stilbon, which is Mercury's; the Sun, finally, sixth, and the Moon seventh. Some of the mathematicians agree with Plato; some put the Sun in the middle of all.*

[Margin: Plato's system, from Plutarch.]

[Margin: And from Macrobius.]

In a not dissimilar way *Macrobius*, Book 1 on the *Dream of Scipio*, chapter 19, teaches that according to Plato the Sun holds the sixth place among the planets and the Moon the seventh; and in chapter 21: *It is to be noted in this place that, at the birth of the world, either the providence of things itself or the genius of antiquity gave the stars this order which Plato assigned to their spheres: that the Moon should be first, the Sun second, above him Mercury, Venus fourth, then Mars, next Jupiter, and Saturn last.* And from these two sources, I believe, all those drew who ascribe this order to the Platonic system: namely *Copernicus*, Book 1, chapter 10; *Valentinus Naiboda* [Valentin Naibod], Book 1 of the *Institutiones astronomicae*, chapter 16; *Clavius* on the *Sphere*, page 64; *Barocius*, Book 1 of the *Cosmographia*, chapter 2; *Orontius*, Book 1 of the *Sphere*, chapter 3; and *Argolus* [Andrea Argoli] in the *Pandosion sphaericum*, chapter 3 — although only Clavius and Argoli express the position of Venus above Mercury, while the rest count both of them above the Sun, according to the opinion of Plato and the Egyptians.

[Margin: Another system of the Platonists.]

II. Some Platonists, however, varied this order somewhat, and raised Mercury above Venus; for so the same *Macrobius* reports of them, Book 1 on the *Dream of Scipio*, chapter 3: *This measurement of Archimedes, however, was rejected by the Platonists, as not keeping the double and triple intervals. And they laid down that this is to be believed: that as great as the distance is from the Earth to the Moon*[30]*, twice that is from the Earth to the Sun; and as great as it is from the Earth to the Sun, three times that is from the Earth to Venus; and as great as it is from the Earth to Venus, four times as much is from the Earth to the star of Mercury; and as great as it is to Mercury from the Earth, nine times as much is from the Earth to Mars; and as great as it is from the Earth to Mars, eight times as much is from the Earth to Jupiter; and as great as it is from the Earth to Jupiter, twenty-seven times as much is from the Earth to the orb of Saturn.* This Platonic persuasion *Porphyry* inserted in the books in which he shed some light on the obscurities of the *Timaeus*. The same order is asserted by the author of the book *De mundo*, addressed to Alexander, by *Apuleius* in his book *De mundo*, and by *Hamerus* on chapter 1 of Genesis. It was not, then, the author of the little book *De mundo* alone who

[30]the page prints "Lunum"

placed Mercury above Venus and Venus above the Sun, as Clavius said (on the *Sphere*, page 42).

[Margin: The opinion of Marsilius Ficinus.]

Marsilius Ficinus attributes the same intervals and the same order to Plato, in almost the same words, in the *Compendium in Timaeum*, chapter 34; but he adds: *Here you see the heavier planets, Jupiter and Saturn, designated by solid numbers; and although elsewhere, following the opinion of some Pythagoreans, I have reviewed other measures of the intervals, I nonetheless judge the Platonic ones more probable.* And by these he thinks it can be explained what is said rather obscurely about these spheres and proportions in Books 8 and 10 of the *Republic*. I should think, moreover, that the handle for these was given by those words of Plato in which he brings in Timaeus of Locri, the Pythagorean, speaking thus: *God placed the Moon in the first circuit above the Earth; the Sun in the second; then the globe of Lucifer, and the star sacred, as it is called, to Mercury, he fixed in circles equal to the Sun in speed but contrary to it in power; so it comes about that these stars — the Sun, Lucifer and Mercury — overtake one another and are in turn overtaken by one another.* But from the fact that he named Venus before Mercury it does not follow that Plato, or Timaeus, placed Venus lower than Mercury.

[Margin: The motion of Mercury undiscovered.]

For in the *Epinomis* he names that planet after the Sun and Lucifer because its motion was undiscovered, or because formerly it had no settled name among the Egyptians. For so Plato speaks there, in the person of the Athenian: *Of the Sun, I say, and of Lucifer, and of that third one which, since it is unknown, cannot be named; and this came about because the first observer of these things was a barbarian: for an ancient region nourished those who, on account of the clearness of the summer season, were the first to look into these things. Such were Egypt and Syria, where all the stars, so to speak, are always seen clearly, because neither clouds nor rains hinder the view of the heaven.* Therefore, because its nature and motion were undiscovered, it received its name later than Venus. And he adds: *But they have also received names from some people; for Lucifer, which is also Vesper, has indeed its reason; while the star which runs equally with the Sun and together with it is called Stilbon from its brightness.*

III. The order of the first system, in which Mercury stood above the Sun and Venus above Mercury, was defended by *Theon* (Book 9 on the *Almagest*, chapter 7); by *Summartus* (in Io. Picus [Giovanni Pico della Mirandola], Book 10 *Against the Astrologers*, chapter 4); and by *Geber* of Seville (Book 7 of his *Astronomy*, chapter 1), where he censures Ptolemy for having said, in Book 9, chapter 1, that the parallaxes of Mercury and Venus are to be neglected, although the parallax of the Sun is 2′ 51″, that of Venus 3′ and that of Mercury 7′, from the Ptolemaic commensurations; then, likewise from the Ptolemaic latitudes, he shows that the Sun can sometimes be partly hidden by Venus and Mercury. But we have already defended Ptolemy against Geber's objections in the preceding chapter, number 6. Geber concludes, however, that it is more probable that Mercury moves above the Sun, and Venus above Mercury, together with the three other

planets, because of their likeness in the composition of the orbs, in the double anomaly, and in stations and retrogradations.

De Syſtemate Ciceronis, eiuſq. Diſſidio à Platonico.

On the system of Cicero, and its disagreement with the Platonic system.

IV. Thus far, then, we should have two forms of the Platonic system: one in which Mercury lay below Venus and the Sun below Mercury; the other in which the Sun lay below Venus and Venus below Mercury — had not *Macrobius* suggested a third form, in Book 1 on the *Dream of Scipio*, chapter 19, where he inquires what order Cicero, and what order Plato, assigned to the Sun among the wandering stars. Cicero had said in that dream, in the person of the elder Scipio: *All things are bound together by nine orbs, or rather globes, of which one, the outermost, is the celestial, which embraces all the rest, itself the supreme god, confining and containing the others; in it are fixed those everlasting courses of the stars that revolve. Beneath it are seven, which turn backward with a motion contrary to the heaven. Of these, one globe is possessed by the star which on earth they call Saturn's. Then comes that brightness, prosperous and salutary to the human race, which is called Jupiter's. Then the ruddy one, dreadful to the lands, which you call Mars. Then, below, the Sun holds nearly the middle region, leader and prince and moderator of the other lights, the mind and tempering of the world, of such magnitude that he lights up and fills all things with his light. Him the courses of Venus on the one hand and of Mercury on the other follow as companions. And in the lowest orb the Moon revolves, kindled by the rays of the Sun. Below it there is now nothing but what is mortal and perishable, except the souls given to the race of men by the gift of the gods. Above the Moon all things are eternal: for the Earth, which is the middle and ninth, does not move, and is the lowest, and towards it all weights are borne by their own tendency.* This is fully and plainly the Ciceronian system, differing in nothing at all from the Pythagorean and the Archimedean.

[Margin: Macrobius's opinion on the system of Cicero.]

But because Plato assigns the Sun the sixth place among the planets, and Cicero the fourth, *Macrobius*, in Book 1, chapter 19, as I said, investigates the causes of this disagreement; for he says: *Plato followed the Egyptians, the parents of all the disciplines of philosophy, who want the Sun to be placed between the Moon and Mercury in such a way that they nevertheless detected by reasoning, and drew out, why the Sun is believed by some to be above Mercury and above Venus; for neither do those who think so stray far from the appearance of truth.* And a little after: *Now next to Venus is the star of Mercury, and the Sun is near to Mercury, so that these three go round their heaven in an equal space of time, that is, in a year, more or less. Hence Cicero too calls these two courses companions of the Sun, because in an equal space they never withdraw far from one another.* And, after interposing a few words about the Moon, he goes on: *The nearness of these three neighbours, Venus, Mercury and the Sun, confused their order — but among others; for the reason did not escape the skill of the Egyptians, and it is this: the circle through which the*

Sun runs is surrounded, as the lower, by the circle of Mercury; and that circle in turn the higher circle of Venus encloses; and so it comes about that these two stars, when they run through the upper tops of their circles, are understood to be placed above the Sun, but when they pass through the lower parts of their circle, the Sun is thought to be above them. Those, therefore, who said that their spheres are below the Sun took this impression from that course of the stars which, as we said, sometimes appears lower, and which is truly the more noticeable, because they then appear more freely; for when they hold the upper parts they are more hidden by the rays. And so that persuasion prevailed, and this order was received into use by almost everyone. A more perspicacious observation, however, detected the better order. Having said this, and interposed some remarks on the light of the planets, he concludes: *What order Plato or his authorities gave to the Sun, or whom Cicero followed in assigning the fourth place to its globe, or what reason introduced the persuasion of this diversity, has been sufficiently stated.*

Cicero, therefore, followed the more common opinion about Venus and Mercury. Because these planets are discerned [?] longer and better when they digress most from the Sun, and are not so hidden by the light of twilight — and at that time they are in the lower semicircle of their epicycle — they are therefore believed to move below the Sun. And the Egyptians followed that very reasoning in the distribution of the planetary hours, as we said from Dio[31] and Xiphilinus in the preceding chapter, number 7, reason 9; granted that, reasoning about these digressions, or else because, enjoying a clearer air, they sometimes saw Venus and Mercury much diminished in apparent magnitude, they judged that this happened because they rose far from the Earth above the Sun, and so described circles about the Sun.

[Margin: Did Plato follow the system of the Egyptians?]

V. If, therefore, Plato followed the Egyptians, as Macrobius says, and the Egyptians taught that Venus and Mercury move not only above but also below the Sun, Plato might seem to have carried this very thing over to the Greeks, although he expressed only the higher position, because he thought that in the harmonic intervals it was rather their greatest distance from the Earth, and their apogee position, that should be kept, than their least distance and perigee place. Indeed Cicero himself too might seem not to have dissented from Plato, although he expressed only the common opinion, since Cicero's book *On the Dream of Scipio* is part of Book 6 of the *Republic*, and in the books on the *Republic* he imitated Plato, who indeed, in Books 8 and 10 of the *Republic*, gives the reason of the harmonic intervals between the seven orbs, attributed to seven sirens — though in a rather involved way. For that reason I elsewhere judged it probable (Book 7, section 1, chapter 4) that the Platonic and Ciceronian system was in reality the same as the Egyptian, to which Vitruvius, Macrobius, Capella and Bede subscribed. But having considered the matter better, I think it more probable that Cicero held with Pythagoras, and, having consulted

[31] the page prints "Dioue", for "Dione"

Plato's *Epinomis*, that Plato dissents from the Egyptians on this point. For Cicero [?] nowhere indicated that order of Plato's; and although he admitted a concert of the heavens, he subscribed rather to the Pythagorean intervals, and followed the opinion which Pythagoras had taught in Italy and which had passed from Numa Pompilius in Latium to Varro and Cicero. Plato, on the other hand, judged that everything received from the barbarians — for so he calls the Egyptians and Syrians and all foreigners — had been made better by the Greeks; and in this business of the system of the world he judged it better that Venus and Mercury should always be above the Sun and should move uniformly on concentric circles, and not by epicycles now below, and now above, ranging about at changed distances. I gather this from his own *Epinomis*, where he says:

[Margin: Plato's opinion on the motion of the stars.]

That what proceeds in order in the heaven has mind is sufficiently shown by this sign: that it always goes by the same path and in a like manner. The necessity of a soul possessing intellect is the greatest of all necessities; for it governs, leading and not led. When the soul, which is best, conducts itself by counsel according to the best intellect, then what is truly accomplished by the power of intellect will come about of necessity, without persuasion, and not even adamant could hold more solidly and more immovably, etc. It ought therefore to have been a proof to men that the stars and that whole circuit have mind, because they always do the same things; for over a very great and wonderful span of time they have already deliberated beforehand what they are to do, and they do not, going up and down, approve now this and now that by their counsel. Hence they neither wander nor revolve outside their ancient order.

Plato therefore judged that the planets are driven by a moving Intelligence along the same path with uniform motion, and are not carried up and down; and that this is the work of a mind which has once chosen what is best and preserves it immovably. In a word, he judged that they are rolled round on circles concentric with the world. And he thought it very probable that in this the Greeks had judged more perfectly than the barbarians. For further on in the same *Epinomis*, speaking of the knowledge of the stars, which became known to the Greeks later than to the barbarians because of the hindrances of a less purified air, he says:

[Margin: Astronomy older among the Egyptians than among the Greeks.]

But since we are further than the barbarians, as we said, from summer clearness, we have come to understand the order of these deities (for so he calls the stars) *more slowly. But whatever the Greeks received from the barbarians, they rendered better. And this we must bear in mind also in the matters we are now treating.*

It remains to represent in one scheme the twofold form of the Platonic system: that is, Plato's, which Theon, Samerius and Geber supported; and that of certain Platonists, namely Porphyry, Apuleius and Ficino.

II. The Platonic System.

Diagram. A woodcut in the left column: concentric circles about a central Earth, drawn with a wavy outline inside a stippled ring, with small six-pointed

stars set on the outermost circle. Two lines of planetary signs run from the outer circles down to the centre, one on the upper left, headed *Plato*, and one on the upper right, headed *Porphyrius*. Each line reads, top to bottom, Saturn, Jupiter, Mars, the two small signs of Venus and Mercury, the Sun and the Moon; in the left line (Plato) Venus stands above Mercury, in the right line (Porphyrius) Mercury stands above Venus.

- Upper left, above the outer circle: Plato
- Upper right, following the curve: Porphyrius (Porphyry)
- Left line, top to bottom: ♄ Saturn; ♃ Jupiter; ♂ Mars; ♀ Venus; ☿ Mercury; ☉ Sun; ☾ Moon
- Right line, top to bottom: ♄ Saturn; ♃ Jupiter; ♂ Mars (drawn with its arrow to the lower left); ☿ Mercury; ♀ Venus; ☉ Sun; ☾ Moon

CAPVT IV.

Chapter IV.

De Syſtemate Aegyptiorum, ſeu Vitruuij, Martiani Capellæ, Macrobij, Bedæ, & Argoli.

On the system of the Egyptians, or of Vitruvius, Martianus Capella, Macrobius, Bede and Argoli.

I. It might seem that the system of the Egyptians has been sufficiently demonstrated from what was said in the preceding chapter, number 4. Yet because its form is very different from the Pythagorean and the Platonic, since it contains the extremes of both, and because what the telescope has at last made manifest in our own age they foresaw by the acuteness of their wit, it is right to discuss it again here, as in its proper place. When they were investigating, then, why Venus and Mercury digress from the Sun not by a whole semicircle — indeed Venus by scarcely half a quadrant of the circle, and Mercury not even by a twelfth part of the circle of the zodiac — and why about their greatest digressions they appear larger, they judged that this came about from an epicycle described about the Sun, on which they moved sometimes below the Sun, sometimes above it, sometimes at distances equal with it; and that they digress from the Sun in proportion to the size of the epicycle, and appear larger because of nearness to the Earth and smaller because of remoteness. Therefore they prepared for us, even then, a most beautiful system and, for this part at least, a most true one. Let Macrobius be heard again, if you please, Book 1 on the *Dream of Scipio*, chapter 19, telling it thus:

[Margin: The system of the Egyptians, from Macrobius.]

Among the ancients there was no disagreement about the order of the three upper planets, which an immense distance distinguishes manifestly and clearly, nor about the region of the Moon, which has withdrawn far from all the rest. But the nearness of these three that are close to one another — Venus, Mercury and the Sun — confused their order; but among others. For the reason did not escape the skill of the Egyptians,

and it is this. The circle through which the Sun runs is surrounded, as the lower, by the circle of Mercury; and that circle in turn the higher circle of Venus encloses. And so it comes about that these two stars, when they run through the upper tops of their circles, are understood to be placed above the Sun; but when they pass through the lower part of the circle, the Sun is thought to be above them. Those, therefore, who said that their spheres are below the Sun took this impression from that course of the stars which, as we said, sometimes appears lower, and which is truly the more noticeable, because they then appear more freely; for when they hold the upper parts, they are more hidden by the rays. And so that persuasion prevailed, and this order was received into use by almost everyone. A more perspicacious observation, however, detected the better order. Truly more perspicacious: an observation which, so many centuries beforehand, by the sagacity of wit alone, anticipated the use of the Belgian spyglass.

[Margin: Macrobius's system.]

From these same words, moreover, it becomes plain that Macrobius gave his vote to this system — especially since in the same chapter he goes on to confirm that these two planets must also be carried above the Sun, because, like the others, they have their own light (for so he held), whereas the Moon is always below the Sun, since it shines with borrowed light and only from the Sun.

[Margin: Vitruvius's.]

II. Nor do I doubt that *M. Vitruvius Pollio*, Book 9 *On Architecture*, chapter 4, recognised the same order. For although he enumerates the planets thus — *the Moon, the star of Mercury, of Venus, the Sun itself, and likewise of Mars, of Jupiter and of Saturn* — following the common opinion, a little later he says: *The stars of Mercury and Venus, however, crowning the Sun itself as a centre with their paths about the Sun's rays, make their regressions backward and their retardations. Also, by their stations, because of that circling, they linger in the spaces of the signs.* In this sense *Scheinerus* too interpreted him, in the *Disquisitiones Mathematicae*, number 22, towards the end.

[Margin: The system of Martianus Capella.]

III. No less plainly *Martianus* Mineus Felix, surnamed *Capella*, in Book 8 of *On the Marriage of Philology and Mercury*, in the chapter whose title is *On the orbs of the planets*, says: *But Venus and Mercury do not go round the Earth.* And in the following chapter, having asserted eccentrics by saying, *It must be known that, in general, the Earth is eccentric to all the orbs of the planets; that is, it does not hold the middle of the circles, which is without doubt the centre of the world*, a little later he sets out what the centre of the circles of Mercury and Venus is, in these words: *For although Venus and Mercury show daily risings and settings, yet their circles do not go round the Earth at all, but circle about the Sun with a looser compass. In short, they set the centre of their circles in the Sun, so that they are carried sometimes above it, but mostly below it, nearer to the Earth. From it Venus is separated by one sign and a half. But when they are above the Sun, Mercury is nearer to the Earth; when below the Sun, Venus, as being curved in a chaster and more widely spread orb.* This African writer could not have painted the Egyptian system in clearer

words. And further on, in a chapter specifically on Mercury, he says: *So much for the Sun. Now it is fitting to look at the courses of the planets, and chiefly of those which revolve about the Sun. For Stilbon, completing a circle of nearly a year, runs through 8° of latitude, driven by an alternating variation. I recalled above that the circles of this planet and of Venus are epicycles, that is, not within their own compass do they enclose the roundness of the Earth.*

[Margin: Bede's system.]

IV. But from Africa we must sail to England, and seek out the opinion of that most learned and venerable priest, namely Bede. In his book *On the Nature of Things*, chapter 13, he speaks thus: *The highest of the planets is the star of Saturn, cold by nature, going through the zodiac in 30 years. Next, Jupiter's, temperate, in 12 years. Third, that of Mars, burning, in 2 years. In the middle the Sun, in 365¼ days. Below the Sun, Venus, which is also Lucifer and Vesper, in 368 days, never standing off from the Sun further than 46°. Next to it the star of Mercury, swifter in its round by 9 days, shining now before the Sun's risings, now after its settings, never more than 22° removed from it. Last the Moon, completing the zodiac in 27 days and a third part of a day.* But Bede may have said this either when he was younger, or while indulging the common opinion for the moment. For otherwise, in the book *On the Constitution of the Celestial and Terrestrial World*, which is found in the first tome of his works, in the chapter on epicycles and intersections — page 383 in my copy — he speaks thus of Mercury and Venus: *That they are carried both above and below the Sun is shown by conjectures in three ways: either by the intersection of the circles; or because they are epicycles, that is, supercircular, so that, not having the Earth as their centre, they make the Sun as it were the centre of their course; or because they measure out the height of the Sun with circles of obtuse or of acute windings.* That is, as I at least interpret it, with ellipses described about the Sun rather than circles. And in the book *On the Elements of Philosophy* too, judging that the Platonic and the Egyptian system are the same, and busying himself to reconcile it with the Chaldean, he says: *Next it must be said why the Chaldeans say the Sun is fourth, but the Egyptians and Plato sixth. It is true that the Sun is below Venus and Mercury, next to the Moon*; and he gives the reason, namely that the cold and moisture of the Moon may be tempered by the hot and dry Sun, and that the Moon may receive light from the Sun from nearer. Soon he adds: *To the Chaldeans, however, it seemed otherwise*; he puts the cause in the intersection of circles that are nearly equal, and: *They intersect one another, then, in such a way that the circle of Venus in its lower part cuts the upper parts of the circles of Mercury and of the Sun, taking in more of Mercury's than of the Sun's. The circle of Mercury in its upper part cuts that of Venus, and in its lower part the Sun's. The circle of the Sun in its upper part cuts those of Mercury and of Venus — more of Mercury's, less of Venus's.* At length, after a few words, he concludes: *Since, therefore, the circle of the Sun is surrounded in the upper parts of those circles, it is rightly said to be below them; but because it sometimes happens that the Sun runs through the upper parts of its circle while those stars run through the lower parts of theirs, and they then appear more freely — for the Sun does not obscure what lies beneath it as much as*

what lies above it — it has been reckoned above them. This hypothesis, however, is very involved, and the one he had pointed to in the first place, by epicycles described about the Sun, is much neater and more convenient.

[Margin: Argoli's system.]

V. Finally, *Andrea Argoli*, in his *Pandosion sphaericum*, chapter 3, chose this very system, ordering Mercury about the Sun and Venus about Mercury on epicycles, but the orbs of Mars, Jupiter and Saturn about the Earth. He adds, moreover, that what Vitruvius and Capella had left unpolished and simple he has fortified with geometrical demonstrations, adding the size of the eccentricities and of the epicycles, and that on these measures he has published tables of the secondary motions, which he affirms agree to a hair with the Tychonic ones, except for the Moon. These measures he sets out in the same *Pandosion*, from chapter 50 to 59. But in asserting, in chapter 3, that Tycho rests on a very weak foundation when he makes Mars at its acronychal rising nearer to the Earth than the Sun — namely, with a greater parallax than the Sun's — and that this observation is almost impossible, he speaks too boldly, as will be plain to anyone who considers the Tychonic and Keplerian foundations in this matter, which we have already treated in Book 7, section 2, chapter 3, scholium 4; section 6, chapter 4, scholia 3 and 4; and chapter 10, scholium 1.

[Margin: Argoli's boldness against Tycho.]

But here is the scheme of this Egyptian, Vitruvian, Capellan, Macrobian, etc. system. Although someone among the more recent writers ascribes it to Martianus Capella, it is nevertheless far older, and from its first origin I judge that it should rather be called Egyptian.

III. The Egyptian System.

Diagram. A woodcut at the head of the right column: concentric circles about a central Earth drawn as a small globe, with small six-pointed stars on the outermost circle. Saturn stands at the top of an outer circle, with Jupiter and Mars on the circles within it. Within these, a small circle is centred on the rayed Sun, carrying Venus at its top; Mercury stands just below the Sun on a second small circle about it; the Moon stands on a small circle about the Earth.

- Top, outer circle: ♄ Saturn
- Below it: ♃ Jupiter
- To its left, on the next circle: ♂ Mars
- Top of the small circle about the Sun: ♀ Venus
- Centre of the small circles: ☉ Sun
- Just below the Sun: ☿ Mercury
- Small circle about the Earth: ☾ Moon

CAPVT V.

Chapter V.

De Syſtemate Eudoxi, Calippi, & Ariſtotelis.

On the system of Eudoxus, Callippus and Aristotle.

[Margin: Which system Eudoxus and Callippus followed.]

I. The first controversy concerns the order of the planets — namely of Mercury, Venus and the Sun (for there is no doubt about the three upper planets, nor about the lowest, the Moon) — as asserted by Eudoxus, Callippus and Aristotle. And first, Eudoxus, since he was Plato's disciple in philosophy (as Laertius attests, Book 8, in the *Life of Eudoxus*), seems to have followed the Platonic system as well; especially since he chose Plato's opinion on concentric orbs, as we shall soon see. But since Callippus did indeed correct the system of Eudoxus, yet kept the concentrics and only added certain other starless orbs, and Aristotle did the same, adding further revolving orbs beyond Callippus's number, and was moreover Plato's disciple, it seems consistent too that Callippus, equally with Aristotle, retained Plato's system as to the order of the planets.

[Margin: The system of the author of *On the World to Alexander*.]

Add to this that Aristotle, in the book *On the World to Alexander*, chapter 2, has this: *Next to this, that is, to the globe of the fixed stars, the circle called that of Phaenon, and also of Saturn, always has its position contiguous; nearest to it is that of Phaethon, which is also called Jupiter's. After this follows Pyrois, called likewise Hercules' and Mars's. After this again is Stilbon, which is believed to be sacred to Mercury, and by some to Apollo; next to it is the orb of Lucifer, which some call the orb of Venus, others of Juno. After it is the orb of the Sun, and finally that of the Moon, nearest to us, extending its bounds right down to the Earth.* And if the author of this little book is called into doubt, these are certainly the words of Aristotle, Book 1 of the *Meteorology*, chapter 4, where he says: *Moreover, if, as is shown in the astrological theorems, the size of the Sun is greater than the Earth, and the distance of the stars from the Earth much greater than that of the Sun, as that of the Sun from the Earth is greater than that of the Moon, then the cone which the Earth casts from the rays of the Sun is not raised very far from the Earth, nor will the shadow of the Earth, which is called night, be up among the stars; but the Sun must look round on all the stars, and the Earth stand in the way of none of them.* He supposes, then, that no stars can fall into the shadow of the Earth because they are much more remote from the Earth than the Sun — granted that so great a distance is not necessary; but he supposed it from the hypothesis of certain astronomers which places all the planets above the Sun. Finally, that Aristotle supposed Venus and Mercury to move above the Sun is affirmed by *Hamerus*, chapter 1 on Genesis; *Valentinus Naiboda*, Book 1 of the *Institutiones Astronomicae*, chapter 16; *Clavius* in the *Sphere*, page 64; Ba- rocius, Book 1 of the *Cosmographia*, chapter 2; *Longomontanus* in the *Astronomia Danica*, Book 1 of the Theorics, chapter 1; *Argoli* in the *Pandosion sphaericum*, chapter 3. Nor can it be denied that their opinion is probable.

[Margin: The order of Eudoxus called into doubt.]

II. These things notwithstanding, it seems, first, that Eudoxus, being a Cnidian and belonging to the Assyrians rather than to the Greeks, must have followed the opinion of the barbarians, namely of the Assyrians and the Egyptians — all the more because, as Laertius narrates in his Life, he heard Plato at Athens for only two months. Being, that is, both pressed by poverty and thrown out by Plato, he was compelled to return home from there; afterwards, supported by the generosity of friends, he set out for Egypt, and after staying there 16 months he at length returned to Athens with many disciples, to vex Plato, who had dismissed him at the start. Therefore, although he chose concentrics, it is nevertheless not certain which form of the Egyptian system he chose: the one which carried Mercury and Venus above the Sun, or the one which carried the Sun above them.

[Margin: And of Callippus.]

I say the same of Callippus, who, being an Asian, is believed to have been devoted to the Chaldean hypotheses, and whose writings were known to Ptolemy (and, I believe, those of Eudoxus too), as is plain from Book 2 of the *Almagest*, chapter 2; and yet in Book 9, chapter 1, Ptolemy puts Venus and Mercury below the Sun on the opinion of the ancients, and attributes the opposite only to more recent writers.

[Margin: And of Aristotle.]

As regards Aristotle: since he himself says, in Book 2 *On the Heavens*, chapter 10, *But now the contrary happens; for the Sun and the Moon are moved by fewer motions than some of the stars, although these are further from the centre and nearer to the first body than they are*, he seems to have spoken not of all the planets but only of some, as being higher than the Sun and the Moon and yet having more motions. Then, having related in the same place that he had seen Mars occulted by the Moon, in order to show that the Moon is the lowest of all, although it has fewer motions than certain planets nearer the fixed stars, he adds: *And similarly they speak of the other stars too — the Egyptians and the Babylonians, who observed them long ago over very many years, and to whom we give much credence about each of the stars.* It is therefore more credible that Aristotle, as to the order of the planets, either followed the system of the Egyptians, or — because he chose concentrics and placed no planets now above and now below the Sun — adhered rather to the Babylonian or Chaldean system, which put Venus and Mercury below the Sun, as we learned from Bede in the preceding chapter, number 4. For Alexander the Great, having taken Babylon, had already brought back into Greece the observations kept there and recorded over very many years, as may be gathered from Q. Curtius. And, as Pliny relates in Book 7, chapter 56: *Epigenes, a weighty authority of the first rank, teaches that among the Babylonians there were observations of the stars over 720 years, inscribed on baked bricks; those who give the least, Berosus and Critodemus, 480* — understand [?] years of observations. Moved, then, by these conjectures, and by the authority of certain Peripatetics on Aristotle's books *On the Heavens* and Book 12 of the *Metaphysics*, I once held that Eudoxus, Callippus and Aristotle, keeping the concentrics, put the

Sun above Venus and Mercury — granted that I now confess the opposite to be probable. Let us now come to the other part of this system, namely to the number and office of the orbs by which they set out the motions of the planets, while keeping the planets' distance from the Earth always at the same interval.

[Margin: The concentrics of Eudoxus.]

III. On the orbs of Eudoxus, Aristotle, Book 12 of the *Metaphysics*, chapter 7, or texts 45 and 46, reports with wonderful brevity as follows: *Eudoxus, then, held that the motion of each — of the Sun, I mean, and of the Moon — takes place in three spheres: the first being the one which accomplishes the motion of the non-wandering stars*, that is, of the primum mobile; *the second for the motion which takes place along the circle that runs through the middle of the signs*, namely along the ecliptic, in longitude; *the third for the motion oblique to the zodiac, in latitude; and that the circle along which the Moon is carried is inclined at a greater latitude than the one along which the Sun is carried.* As though the Sun did change its latitude somewhat. *The motion of the remaining wandering stars he held to take place in four spheres each: the first and the second undergo the same arrangement as for those; for both the one which has a motion like the motion of the fixed stars and common to all, and the one placed below it, whose motion is along the circle through the middle of the signs, are common to all. The poles of the third sphere of each lie in the circle which passes through the middle of the signs; and the motion of the fourth cuts this circle obliquely and in two. The poles of the third sphere are proper to each of the other stars, but those of Venus and of Mercury are the same.* From this it appears that Eudoxus assigned one sphere to the fixed stars, three to the Sun, three to the Moon, and four to each of the lesser planets — that is, 27 in all; and that he did not think the lower spheres were swept along by the sphere of the fixed stars, but that each planet was rolled by its own sphere with the daily motion through the meridian to the west. Moreover, that he attributed the variation of the obliquity of the ecliptic and of the Sun's greatest declination at the solstices, which some assert, to the motion of the Sun in latitude: for he did not think, says *Simplicius* on Book 2 *On the Heavens*, that the Sun always proceeds under the ecliptic. Each planet, therefore, had one orb for the common motion from east to west; a second for its proper motion under the zodiac towards the east; and a third for the motion of latitude, from south to north. This third orb, as Io. Bapt. Amicus gathers from Simplicius and Theophrastus in his little work *On the Motions of the Celestial Bodies*, chapter 1, completed its motion in the time in which each planet completes its [Greek: Μετάβασιν (metabasin, "passage")], that is, its transit through the aspects to the Sun; and this time, according to Eudoxus, was 18 months for Venus, 110 days for Mercury, 8 months and 20 days for Mars, and 3 months and 10 days for Jupiter and Saturn. The fourth orb, as the same writers and Delphinus (chapter 5 *On the Celestial Globes*) explain, carried the body of the planet, and, by resisting the third orb, prevented the planet from reaching the poles of the zodiac; and therefore the planet described with its centre a certain line which Eudoxus called the [Greek: ὑποπέσην (so printed; the term meant is ἱππoπέδην, hippopedēn, "horse-fetter")]. Eudoxus

also wrote a little book [Greek: περὶ ταχυτήων (peri tachytēōn, so printed; the title meant is περὶ ταχυτήτων, "On speeds")], and other works which have not come down to us. *Fracastorius*, however, interpreted Eudoxus and Callippus otherwise, from mere conjectures, in the *Homocentrica*, section 3, chapter 25; let anyone who cares to waste his effort consult him.

[Margin: The homocentrics of Callippus.]

IV. Callippus of Cyzicus, a contemporary of Aristotle, added to the homocentrics of Eudoxus some other orbs, likewise concentric with the world. For of him Aristotle, Book 12 of the *Metaphysics*, text 47, after setting out the orbs of Eudoxus, writes thus: *But Callippus posited the same position of the spheres as Eudoxus, that is, the order of the intervals, and the same number for Saturn and Jupiter; but he thought that two further spheres must be added to the Sun and two to the Moon, if one wished to give the causes of the things that appear to the senses; and to each of the other wandering stars, one.* Alas, how meagrely Aristotle puts it! Now Eudemus, as Simplicius reports, said that Callippus did this because he wished to save, in the Sun, the delay of the equinoxes and solstices observed by Almeon and Meton; but others, says Delphinus in the place cited above, devised other causes: in the Moon a certain new inequality, and in Mars, Venus and Mercury one sphere each, because of their stations and retrogressions. Moreover, from what Aristotle has said, it becomes manifest that Callippus's spheres were 33, and 34 with the sphere of the fixed stars: namely one of the fixed stars; four each for Saturn and Jupiter; five each for Mars, Venus and Mercury; and finally five each for the Sun and the Moon. Aristotle, however, counts 8 star-bearing spheres and 25 starless ones, that is, 33, as we shall soon see.

[Margin: Aristotle's revolving spheres.]

V. Finally, Aristotle himself, in the same Book 12 of the *Metaphysics*, text 47, after setting out Callippus's opinion on the number of the concentric spheres, wrapped up rather than unfolded his own opinion in these words, and the common translator poured in no little cuttlefish ink; but we translate that text more clearly thus: *It is necessary, however, if the spheres already mentioned, put together, are to restore each planet to its former place, to set under each of them as many other spheres, less one, which revolve them back and bring the first sphere of the star that is ordered below into the same position. For only in this way can it come about that all of them accomplish the motion of the wandering stars. Since, then, the spheres in which the stars are carried are eight, and the remaining ones twenty-five, of these only those do not need revolving back which carry the body of the planet, or which are the lowest in their order. Those which revolve back the spheres of the first two will be six; those which revolve back the spheres of the four after them, sixteen; and the number of all of them, both of those which carry and of those which revolve these back, fifty-five. But if one does not add to the Moon and the Sun the motions we spoke of, all the spheres will be forty-seven.* These words still seem like a riddle; but we shall solve this riddle if we lay open Aristotle's meaning point by point. First, then: among the partial spheres whose number he is inquiring into, Aristotle does not count the first, although he presupposes it, because,

being endowed with a single simple motion, it needs no other orb. Hence it is that he does indeed count eight orbs of Eudoxus provided with stars, but 25 that are ἀνάστρους [Greek: anastrous, "starless"], that is, lacking a star, or not carrying the body of a star; and the sum of these is 33. Second, Aristotle adds no revolving spheres to the Moon. For although at the end he may seem to say that he has added revolving spheres to the Moon and the Sun, he by no means says this; what he says is that if revolving spheres are not added to the Moon and the Sun, of the kind, namely, that he had added to the first two planets and to the four remaining ones, the number of spheres is 47. As for why he did not fear that the Moon would be swept along by the higher orbs, and so why it had no need of revolving spheres, the reason was perhaps the wonderful speed of the Moon in its own proper motion; or rather, that the Moon has no orbs beneath it to which it might communicate its motion. Third, he thinks that one revolving sphere apiece must be added to all the other spheres of the planets, but only to the starless ones, to prevent or compensate the sweep of the higher ones; but to the spheres carrying the body of the planet he adds no revolving sphere. Fourth, reviewing Callippus's number of starless spheres, he counts as many revolving spheres for them: namely, 6 for Saturn and Jupiter together, and four apiece for Mars, Venus, Mercury and the Sun, and so 16 together, and none for the Moon. In Callippus, however, there were 5 lunar spheres, and 5 for the Sun, 5 for Mercury, 5 for Venus, 5 for Mars, 4 for Jupiter and 4 for Saturn. When these are brought into one sum, the planetary spheres come to 55. Fifth: since the stations and retrogradations[32] of Mars, Mercury and Venus were more evident in that age than those motions on account of which Callippus added two spheres apiece to the Sun and the Moon, if someone wishes to mix the Eudoxian number with the Callippic — following Eudoxus as regards the Sun and the Moon, since he gave the luminaries three spheres apiece, six taken together, but following for the remaining planets the Callippic number increased by the revolving spheres — the planetary spheres come out at 47. To make this reckoning more evident, we set out the numbers of the spheres according to these three authors.

Number of the spheres.

Planet	Eudoxus	Callippus	Aristotle: starless	Aristotle: all, with the revolving spheres (Callippic)	Aristotle: all, with the revolving spheres (Eudoxo-Callippic)
♄ Saturn	4	4	3	7	7
♃ Jupiter	4	4	3	7	7
♂ Mars	4	5	4	9	9
♀ Venus	4	5	4	9	9
☿ Mercury	4	5	4	9	9
☉ Sun	3	5	4	9	3
☾ Moon	3	5	4	5	3
Sum	26	33	26	55	47

[32]printed *tetrogradationes*

Planet	Eu-doxus	Cal-lip-pus	Aristotle: starless	Aristotle: all, with the revolving spheres (Callippic)	Aristotle: all, with the revolving spheres (Eudoxo-Callippic)
With the fixed stars	27	34		56	48

[Margin: Errors of others on the Aristotelian number of spheres.]

VI. From this you now see how great the number of spheres really was for Eudoxus, Callippus and Aristotle, and how variable, according as the sphere of the fixed stars was or was not counted in, and according as the Callippic hypothesis alone, or one mixed from the Callippic and the Eudoxian, was used. The numbers some writers give therefore by no means stand, nor can they rest on Aristotle's text. Take Kepler, who says of Eudoxus, Callippus and Aristotle in the *Commentaries on Mars*, chapter 2: *For since those authors employed 25 orbs to demonstrate the whole inequality of the planets, Aristotle, believing the heaven to be packed with solid orbs, judged that 24 others, revolving ones, should be interposed, so that each lower orb should be freed from the sweep which, through the contiguity of the surfaces, it would suffer from the higher. Therefore, having accumulated 49 orbs in all (or, according to Callippus, 53 or 55), he added a mover to each one.* Nor do Io. Antonius Delphinus, in his book *On the Celestial Globes and Motions*, chapter 8, or Fracastoro, section 3, chapter 25 — where both expound this passage of Aristotle with the greatest diligence — give the correct number. For Delphinus says that Aristotle has 55 by the Callippic reckoning but 49 by the Eudoxian; yet he correctly counts the Callippic spheres separately as 34 and the Eudoxian as 27, with the fixed stars. Fracastoro, for his part, does not count 47, but leaves out Aristotle's second computation. Hevelius too, in chapter 7 of the *Selenographia*, wrongly counts the Aristotelian orbs as 53 or 54. The Coimbra commentators [Conimbricenſes], in Book 2 of the *De caelo*, chapter 3, question 8, article 2, give 47 or 50; and Mastrius and Bellutus [Bartolomeo Mastri and Bonaventura Belluto], disputation 2 on the *De caelo*, question 1, number 35, give 55 or 57. But all of them stray in some respect from the true number. For Aristotle has 55, and with the sphere of the fixed stars 56; but if he subscribes to Eudoxus as regards the Sun and the Moon, and to Callippus in the rest, there are 47, and with the sphere of the fixed stars 48.

VII. Sosigenes, as Simplicius relates, uncovered many imperfections in this system, inasmuch as it did not save many of the phenomena of the planets. But it certainly errs most of all in this, that it uses homocentric spheres; for from the variation of the lunar parallaxes, and of the apparent magnitude of the planets, it has now become evident, physically and optically, that the planets are at one time higher and at another lower [?]. Rightly, therefore, he rejected the homocentrics and took refuge in the Pythagorean eccentrics and epicycles.

CAPVT VI.

Chapter VI.

De Syſtemate Auerrois, Alpetragij, Delphini, & Io. Bapt. Amici.

On the system of Averroes, Alpetragius, Delphinus and Io. Bapt. Amicus.

[Margin: The system of Averroes.]

I. How doubtful and inconstant Averroes was about the system of the heaven is clear from *De caelo* 2, commentary 35, from *Metaphysics* 12, commentary 45, and from his commentaries on the *Almagest*; for there, as to the order of the planets, you cannot tell whether he subscribes to Ptolemy or rather to others, although he leans towards Ptolemy's order. He nevertheless strives with many arguments to overthrow the eccentrics and epicycles and to substitute the ancient concentrics in their place. In that commentary 35 he promises that, if God prolongs his life, he will treat of that theory of the celestial motions which was cultivated in Aristotle's time, and which he reckons agreeable to physical principles; but in *Metaphysics* 12, commentary 45, acknowledging himself worn out with old age, he despairs of the matter, exhorts posterity to it, and hopes that someone will not be wanting to take up this task. And not much later Alpetragius appeared, who turned his mind to it. His work is entitled *Theorica Planetarum, physicis rationibus probata* [*Theory of the Planets, Proved by Physical Reasons*], because he suspected that Ptolemy's hypotheses, while not indeed impossible as theory, conflict with physical principles and get in each other's way; although, as to the numbers of the motions and the periods of the times, he follows Ptolemy to the letter. Moreover, at the end of this work he himself admits that he has passed over many other particulars bearing on the motion of the planets which are in Ptolemy's *Almagest*, because he saw that he was now worn out with old age.

[Margin: The system and hypotheses of Alpetragius.]

II. First, then, Alpetragius teaches that there is a ninth sphere, which is moved by one Intelligence with the single, most perfect motion of the primum mobile, in the space of 24 hours, from east through the meridian towards the west; and that the same Intelligence impresses its motion on the eight lower spheres, but uniformly difformly, ever slacker and slacker. Hence the sphere of the fixed stars is moved somewhat more slowly towards the west and does not revolve wholly back to the same meridian in 24 hours, but in a somewhat greater small addition of time; the sphere of Saturn, again, is moved more slowly still, and the sphere of Jupiter more slowly than this, and the sphere of Mars more slowly than this, and Venus than Mars, and the Sun than Venus, and Mercury than the Sun, and the Moon than Mercury. This is because, through an imperfect participation in that impulse, they are more sluggish; and so observers were deceived into thinking that the fixed stars and the planets have a proper motion contrary to the motion of the primum mobile, whereas in reality they are not moved by a contrary motion, but by a motion of the same kind, though slower and slower the further they are from the sphere of the primum mobile.

III. Second, he establishes in chapters 8, 9 and 11 that Venus must be placed above the Sun, but Mercury below it, because it revolves back to the same meridian more quickly than the Sun and is therefore nearer the highest sphere. In the same place he affirms that Venus and Mercury have a light of their own, and that therefore, although Mercury comes between our eye and the Sun, it does not darken any part of the Sun. Further, he ascribes the slowness and speed of the motions, and all their inequality, as well as the stations and regressions, to the motion of the poles of each sphere, which describe various small circles around the poles of the world or of the ecliptic. But it follows from his Theory that the planets always keep the same distance from the centre of the world; and yet he gives no reason why they appear smaller and larger than themselves. The planets, moreover, describe a kind of spiral, in Arabic *laulabina*, but on the same spherical surface.

[Margin: The system of Io. Antonius Delfinus.]

IV. Io. Antonius Delphinus of Casalmaggiore, of the Franciscan order, in his book *On the Celestial Globes and Motions*, from chapter 30 on, posits, besides the Empyrean, a ninth sphere or crystalline heaven, to which he assigns the office of the primum mobile; but he holds that each sphere has its own Intelligences moving it westward along spiral lines. As to the order of the planets, he follows Ptolemy, but he uses concentrics; and the cause for which the planets appear to have different magnitudes he attributes to the varying density and opacity of the air, through which the apparent disc of the stars is enlarged by refraction, and to the varying disposition of the eyes.

[Margin: The system of Io. Bapt. Amicus.]

V. Io. Baptista Amicus, by contrast, in his short work *On the Motions of the Celestial Bodies according to Peripatetic Principles, without Eccentrics and Epicycles*, defends Aristotle's revolving spheres and uses homocentrics; the cause of the varying apparent magnitude of the same planet he lays partly on the deception of sight and of instruments, partly on the varying temper of the air. In the eighth sphere, however, he admits a proper motion towards the east, and an unequal one at that. He therefore posits ten spheres, of which the tenth is the Primum Mobile, and the ninth and the eighth serve for the motion of the fixed stars, which is equal in itself but unequal by accident, through a titubation or trepidation, exactly as the Alphonsines held; and he also follows their order in placing the planets. Nor does he recognize any superior planets other than Saturn, Jupiter and Mars. The systems of these men, however, are so obsolete that it is not worth drawing a figure of their own to explain them; let it be enough to have indicated their hypotheses.

CAPVT VII.

Chapter VII.

De Syſtemate Io. Bapt. Turriani & Hieronymi Fracaſtorij.

On the system of Giovanni Battista della Torre and Girolamo Fracastoro.

I. I shall begin with the letter which Girolamo Fracastoro of Verona, outstanding in the adornments of astronomy, medicine and poetry, wrote to Pope Paul III in order to dedicate his *Homocentrica* to him. In it he affirms, among other things, that all philosophy, indeed nature itself and the celestial orbs themselves, had always protested against the eccentrics and epicycles of Hipparchus and Ptolemy; and that many had therefore striven, but with vain labour, to explain the causes of the celestial motions in another way. He then relates as follows:

[Margin: Praise of Io. Bapt. Turrianus for his astronomy.]

In our age Io. Bapt. Turrius, our fellow citizen, a man of the greatest and almost divine genius, and a cultivator of a certain more secret philosophy, discovered two wonderful motions in the spheres — those, I believe, which both al-Battānī and most other astronomers divined lay hidden in the stars. Through them he seemed to himself to have found an entry to many things, but chiefly to demonstrating without any eccentrics the things that are seen about the stars. He had begun to turn this matter over in his mind with great hope when, fortune deciding otherwise — he would better have said, God — *he was overtaken, at its very beginnings, by an untimely and unexpected death: a young man in age, most flourishing and admirable in talent, in studies, in virtue and in every discipline. When he was now about to die* (just as they say Mercurius Trimegistus [Hermes Trismegistus], dying, asked the friends standing by to remember that ship which he had taught to rise and descend perpetually in the midst of the aether)*, he turned to us, his friends who stood by, and after he had said many other things, then, looking at me, he said: "There is something, Fracastoro, that I would ask of you last of all." When I urged him to say it, he said: "I would have you remember those circles which Timaeus first cuts in the shape of the letter X and then bends back so that the ends of the lines meet"* (he meant the motions he had discovered)*; "for if I may hope that you will accomplish what death now begrudges me, and complete the business I have begun, it will be a great consolation to me as I die." And I to him: that I would remember, etc.*

[Margin: Fracastoro, reviver of the homocentrics.]

II. This, then, was what led Fracastoro to think out how he could explain all the celestial motions by homocentric orbs alone, that is, by orbs concentric with the centre of the world. But to accomplish this he had to give a reason why the Moon and the other planets appear at times larger than themselves and at times smaller; and since he could not refer this either to eccentrics or to epicycles, which had been banished from his hypothesis, he tried, in section 1, chapter 8, and in section 3, chapter 23 — which is entitled *On the variation of view in the quadratures, and in fast and slow motion* — to put the cause down to a variation in the medium: if not in the air, at least in a heaven rarer in some places and denser in others; a heaven, I mean, lying beneath the Moon, which moves in such a way that whenever the Moon is in the quadratures it

shows its disc larger in appearance than usual, because of the refraction of the solar rays in the denser but transparent part of that zone which glides between, beneath the zodiac and beneath the Moon. But this man, otherwise so great, does not seem to have understood what that variation of view is from which Ptolemy shows the variation in the Moon's distance from the Earth. For it is not merely a difference of apparent magnitude, but the difference between the true place and the place seen by us from the surface of the Earth — as we have often set out, but chiefly in Book 1, chapter 35, Book 3, chapter 7, and Book 4, chapters 13 and 14. When these last passages are read again it will be clear that the difference of the lunar parallaxes is so great, and of such a kind, that its cause cannot be put down to the Fracastorian refraction, nor yet to the nearness of the greater light, which is the other cause he adduces. Moreover, Fracastoro presupposes the Ptolemaic order of the planets. Finally, he devises a great many homocentrics, by whose means the inequality of the proper motion of the fixed stars and of the planets is produced. I shall list them briefly, useless though they are.

[Margin: The orbs of the Aplanes: 7.]

III. First, then, for the Aplanes, or sphere of the non-wandering stars, he employs 7 orbs, in section 2, chapter 17. The first and highest is the *Primum mobile*, carrying all the lower ones with it; its motion, the simplest of all, is made in 24 hours from rising to setting along the equator. The second is the *Circumducens* [the leading-round orb], which, carried round in latitude along the upper colure from north to south in 3600 years, rolls all the lower orbs with it, except in so far as some, carried the contrary way, hinder it; the circle of its motion cuts the equator at right angles and has its poles on the equator. The third is the *Circitor* [the circling orb], whose circle, subordinate to the lower colure of the equinoxes, is carried round in latitude by the upper circle in 3600 years; but of itself it moves everything in the opposite direction, and it completes 4° in the time in which the Circumducens completes the quadrant of its circle. The fourth orb is called the *Contrauectus* [the counter-carried orb], carried contrary to the Circitor and to the Circumducens in latitude; moving twice as fast as the Circumducens, it is carried along the upper colure from south to north. The fifth is the *Anticircitor*, which is rolled by the fourth in latitude, always to the side opposite to the Circitor, and proportionally; from this it comes about that by its proper motion it is always opposed to the Circitor in latitude, but agrees with it in longitude and drives in the same direction. And so that the Aplanes is not moved in latitude, that is, so that the fixed stars do not vary their latitude, a Contrauectus follows the Anticircitor and prevents this motion. Last, in the seventh place, is the Aplanes, that is, the sphere of the fixed stars itself, which of itself, by its mean motion, completes one degree in 100 years, but by accident now more quickly, now more slowly; and the period of its equality is completed in 3600 years.

[Margin: The orbs of the planets.]

IV. To Saturn, moreover, Fracastoro assigns 10 orbs, in section 2, chapter 21; to Jupiter 11 orbs, in chapter 24; and to Mars 9, in chapter 27. In section 3, chapter 10, he gives the Sun 6 orbs, or at least 4; in chapter 15, Venus 11 orbs; and in chapter 19 to Mercury 11 orbs; and finally, in chapter 24, he assigns 7 orbs to the Moon. These orbs he calls Circitores, Circumducentes, Contrauecti, Anticircitores, and so on; and to them he adds 7 orbs carrying the bodies of the planets. There is no need to shake out the superfluous furniture of this hotchpotch of solid orbs, since we have already rejected solid orbs in section 1, chapter 7, and have established the variation of the distances from the Earth in each planet by far stronger arguments in Book 7, section 6, chapter 1. For the sake of a little erudition only, therefore, it is enough to know that the sum of Fracastoro's homocentric orbs rises to the number 77 or 79; but if you count the starless orbs, Scheinerus rightly said that there are at least 70, or else 72, as is clear from the following small table.

Fracastoro's orbs.

Orbs of	Number
the Aplanes	6
Saturn	10
Jupiter	11
Mars	9
the Sun	4 or 6
Venus	11
Mercury	11
the Moon	7
Star-bearing	8
Sum	77 or 79

CAPVT VIII.

Chapter VIII.

Et Syſtemate, Tychonis, Longomontani, Blancani & multorum Tychonis ſectatorum.

And [?] the system of Tycho, of Longomontanus, of Blancanus and of many followers of Tycho.

I. The Tychonic system is proposed and expounded by Tycho himself in volume 1 of the *Progymnasmata*, from page 477, and in the letter to Rothmann dated 1589 February 21, old style; but more fully in volume 2 of the *Progymnasmata*, chapter 8, from page 185. This system, but with the diurnal motion of the Earth taken on, was chosen by Longomontanus in the *Astronomia Danica*, Book 1 of the Theorics, chapter 1, and by Blancanus in the *Sphaera*, together with most members of our Society in their writings on the heaven; and Scheinerus inclines to it in the *Disquisitiones Mathematicae*, number 22. Io. Antonius Maginus afterwards commended it in a letter to Tycho dated 1590 September

13 [Idibus Septembris], which is found on page 52 of Tycho's own *Mechanica Astronomica*; and on it he built the tables of the *Supplementum Ephemeridum*. Tycho, then, judged the assumption of epicycles together with the Ptolemaic eccentrics to be inelegant, indeed superfluous, and held that the Ptolemaic equants likewise sin against the first principles of this art, since they suppose that the planets move with some physical inequality — that is, that they do not move uniformly about the centre from which they are described, but about another centre. On the other side he was offended by the Copernican system, by which the absurdities of the Ptolemaic system are emended only in such a way that one falls into a greater absurdity: because of the diurnal and annual motion of the Earth, contrary to the principles of physics and to Holy Scripture, and because of the immense vastness between Saturn and the fixed stars. For these reasons, as it were, he turned his mind to another, new system, and set it out for us in the following scheme.

[Margin: Exposition of the Tychonic system.]

II. In this system the Earth rests at its own centre in the centre of the universe, wholly free of annual motion; and from the same centre is described the outermost or highest sphere of the fixed stars, advancing slowly eastward with an equal proper motion. Further, the centres of the orbs of the Sun and the Moon turn about the centre of the Earth, since these serve to distinguish the times. But the centres of the orbs of the five lesser planets, he denies, turn about the centre of the Earth or look to it of themselves; rather, they turn about the Sun and measure their eccentricities from it. For in this hypothesis all these five planets have the Sun as the centre, so to speak, of their revolutions, so that the Sun, like Apollo in the midst of the Muses, governs the whole harmony of the planetary choir. From this, therefore, he hopes that not only the cause of the inequalities, the stations and the regressions can be accounted for, but also that of the admirable connection which the other planets have in their motions with the motion of the Sun; and he promises to account for it in his work *On the Restoration of Astronomy*. What is most worth noting, moreover, appears in this scheme: Mars when acronychal — that is, when it appears at both ends of the night, being opposite the Sun — descends so far towards the Earth that it becomes nearer the Earth than the Sun itself. This must happen both on the hypothesis and observations of Copernicus and on Tycho's own observations, according to what was said in Book 7, section 2, chapter 3, scholium 4, and section 6, chapter 10, scholium 1. The result is that the circle on which Mars is carried intersects the orb or circle on which the Sun itself is carried; but no physical absurdity arises from this, since for Tycho the whole heaven is liquid and permeable, as I taught in section 1, chapter 7.

IV. The system of Tycho and of Blancanus, and in some respects of Longomontanus.

Diagram. A woodcut in the right column showing the Tychonic system. An outer double circle, studded with small stars, encloses the whole; at the centre is a dark disc, the Earth, which carries no sign. Inside the ring of the

fixed stars stand the circle of Saturn and, within it, the circle of Jupiter, each marked by its sign near the top and again near the bottom. About the Earth run a small circle carrying the Moon, set as a crescent just above the Earth, and a larger circle carrying Mars below the Earth. Above the Earth the rayed disc of the Sun carries two small circles, with the signs of Mercury and Venus on them. The circle of Mars intersects the circle of the Sun. A dark smudge to the upper right of the figure carries no sign.

- Top of the outer planetary circle: ♄ Saturn
- Below it, top of the next circle: ♃ Jupiter
- Upper small circle about the Sun: ♀ Venus
- Inner small circle about the Sun: ☿ Mercury
- Centre of the small circles: ☉ Sun
- Just above the Earth: ☾ Moon
- Below the Earth: ♂ Mars
- Near the bottom: ♃ Jupiter
- Near the bottom, lowest: ♄ Saturn

[Margin: The theft of Nicolaus Dithmarsus, and his error about Tycho's system.]

III. In the letter to Rothmann indicated in number 1, Tycho complains that this system of his was passed off by Nicolaus Raymarus Ursus Dithmarsus [Nicolaus Reimers Ursus] as his own; but he convicts him of theft or plagiarism, from the fact that this Nicolaus had been Tycho's servant and had fled from him, and had copied this system for himself from a certain imperfect scheme in which, however, through carelessness, the orb of Mars enclosed the whole orb of the Sun without any intersection. So, since he was unable to correct that error, he boasted of the Tychonic system, though stained with this fault, as his own before Wilhelm, Landgrave of Hesse. Tycho therefore affirms there that by this single indication alone the man's imposture is manifest; and so does Longomontanus in the preface to Book 1 of the Theorics. He adds, moreover, that it was not the Copernican hypothesis inverted that gave occasion to these hypotheses[33] of his — for he had seen no such inversion — but both the approach of acronychal Mars to the Earth and the phenomena of comets, which he judged could not be explained otherwise if the annual motion of the Earth were excluded. Granted, Rothmann did object this to him, namely, that his hypothesis was the Copernican one inverted, as appears from Tycho's *Epistolae*, page 128.

[Margin: The agreement and disagreement of the Tychonic and Copernican systems.]

IV. As for Scheinerus's assertion, in the *Disquisitiones Mathematicae*, number 22, that the Tychonic system shares nothing with the Copernican, it must be taken with a grain of salt. It is true as regards the annual motion of the Earth, the rest of the fixed stars, their distance, and the other things that depend on

[33] printed *hypotheſibns*, a turned u

these; otherwise there are many things common to both systems. Namely: the Sun is the centre of the planetary system, the Earth the centre of the lunar motion; Mars in opposition to the Sun nearer the Earth than the Sun.

Whether Tycho admitted the diurnal motion of the Earth is commonly doubted. For he nowhere taught by what means the fixed stars and the planets are moved with the diurnal motion; and in volume 2, page 187, he seemed to repudiate only the annual motion of the Earth, in these words: *I judge that it must be laid down beyond all doubt — with the ancient astronomers and the received opinions of the natural philosophers, and with the sacred Scriptures moreover attesting this very thing — that the Earth which we inhabit occupies the centre of the universe and is not turned round with any annual motion, as Copernicus wished*; and Kepler thought that he was not averse to this motion.

[Margin: Tycho accepts neither a diurnal nor an annual motion of the Earth.]

But if what he himself contrives against Copernicus's hypothesis in the letters to Rothmann is read attentively, it will without doubt be judged that Tycho denied every motion to the Earth, and indeed that he brought a particular argument against the diurnal motion, both from the opinion of St Augustine and from the perpendicular fall of a lead ball. For in the letter of 1589 November 24, old style, page 156, he says: *The question was raised whether the mobility of the terrestrial globe — and that a threefold one, as asserted by Copernicus — can really hold, whether it ought to be preferred to our discovery, and whether the sacred Scriptures are contrary to that imagination of his or not. If, therefore, you have anything from the sacred oracles or from their interpreters, such as Augustine or other Fathers, that makes for this Copernican assertion and for your agreement with it, cite it from their writings. Provided the reasons are sound, I shall not resist. This much I know well: that Augustine, whom alone you name, never granted the Earth either an annual or a diurnal motion, inasmuch as, being less of a mathematician, he detracted from its roundness by denying the Antipodes. This, however, must be forgiven him. Therefore, since he did not perceive that it is round, he could far less admit a motion proper to roundness.* And at the end of the same letter he adds: *But since I see that the Copernican opinion about the threefold motion of the Earth pleases you greatly, I shall propose on each of these at least one doubt, and not a very laborious one, though more could be given. First, as regards the diurnal motion about its own axis, by which the Earth is imagined to be turned round in 24 hours, and the universal course from east to west is thus accounted for: tell me how it could happen that a lead ball let fall in the proper way from a very high tower should touch exactly the point of the Earth placed perpendicularly below it. For geometrical computation will teach you that this could by no means happen while the Earth is meanwhile carried round, since its course is very swift: in a single second of time the Earth would have to turn, even in these northern regions, approximately 150 greater paces. From this, reason out the rest. For the falling lead does not accompany the air, but passes through it violently.*

When Rothmann replied to this, in a letter of 1590 April 18, that according to Copernicus's view heavy and light bodies are endowed with two motions

— one by which they follow the motion of the whole in a circle, the other by which they tend upward or downward — Tycho pressed against him again, adducing a further argument from balls fired from a cannon, one towards the east and the other towards the west, as may be seen in his letters from page 190. Again, in volume 1 of the *Progymnasmata*, after confirming from its diurnal motion, by which it complied with the motion of the primum mobile, that the new star of 1572 was celestial, he says: *Unless perhaps we were willing to assent that that universal motion takes place in the Earth, as pleased Copernicus and certain of the ancients; which, however, must in truth by no means be conceded, as we shall make abundantly plain elsewhere.* It must be concluded, therefore, that neither an annual nor a diurnal motion of the Earth ever appealed to Tycho.

[Margin: Tycho's system defective in the diurnal motion.]

From this, however, it is gathered that his hypothesis is incomplete, since he never taught how, in a liquid heaven, the stars can perform both the motions that appear to us without physical contradiction — an imperfection that Galileo also noted in his *Trutinator*, page 25; nor did Kepler sufficiently wash out this stain in the *Hyperaspistes*, page 190.

[Margin: Censure of Tycho's system by Rothmann and others.]

V. Rothmann detected another imperfection, too, in Tycho's system, as he himself reports in his letter of 1588 September 19 [13. Calendas Octobris]: namely, a confusion of the spheres, chiefly because Venus, Mercury and Mars are made to wander up and down through the heaven of the Sun. For he says: *Moreover, this inverted scheme of Copernicus introduces confusion into the spheres of the planets. For although no collision of the celestial bodies can follow from it, as you strive to plead, yet no true or determinate distinction of the spheres remains, but all are confused with one another. The Copernican hypothesis, by contrast, assigns to each planet its own determinate space, from which it cannot depart in its motion. And you know that God is the author not of confusion but of order, and that he so founded Nature that she abhors confusion.*

[Margin: The censure of Herigonius and others.]

The same objection is made against him by Malapertius [Charles Malapert], Tannerus and Amicus, in the places cited in Book 7, section 6, chapter 4, scholium 4, and by Herigonius [Pierre Hérigone] in volume 5, page 548; and further, that it is not likely that the larger circles of 5 planets are carried round by the smaller circle of the Sun. But the first objection is answered by Tycho, page 149, in the letter of 1589 February 21, in these words: *Nor is any confusion committed in my hypotheses; for the heaven is one and like itself from the Moon to the eighth sphere, and in it the planets ascend and descend freely, according as they go round the Sun, which walks in their midst, in the most beautiful harmony. For I do not believe that you wish to introduce once more any real distinction of the celestial orbs, against which we agreed between ourselves long ago.* The second objection also falls, because the Sun's circle carries the other circles not effectively but objectively, and is the centre to which their motions look.

Accordingly Longomontanus, in Book 1 of the Theorics, chapter 1, extols Tycho's system and hypotheses with wonderful praise, because in the three superior planets the orbs described about the Sun play the part of the Ptolemaic epicycles — that is, because the single annual orb of the Sun serves them as a single great epicycle — while, conversely, the epicycles of Venus and Mercury described about the Sun serve them as orbs; and so each and every one of the lesser planets has its own orbs eccentric to the Sun.

[Margin: In what Longomontanus's system differs from Tycho's.]

VI. Longomontanus himself, however, thought that the diurnal motion of the Earth should be introduced into the Tychonic system, as Origanus had done: on the one hand, so that by this single motion, and a uniform one, the apparent motion of the stars towards the west might be represented, while in reality they have a single and simple motion towards the east; on the other, so that the incredible speed of the diurnal motion might be taken away from the fixed stars. Indeed, he does not attribute any real proper motion at all to the fixed stars towards the east; for he fears that this would lead to their being drawn apart from one another and to a variation of their distance, which has nevertheless never been found to vary. That fear would be empty, and would vanish altogether, if he made the heaven of the fixed stars solid and the stars fixed in it; but he makes that heaven, not to mention that of the planets, fluid and most limpid, and the single globes of the stars hanging in balance in the free aether, in the way that the Earth hangs balanced in the air. Accordingly he attributes the apparent motion of the fixed stars to a precession of the equinoxes taking place in the Earth. So Longomontanus has it in Book 1 of the Theorics, partly in chapter 1, page 161 of my copy, partly in chapter 4, page 220 of my copy.

Moreover, when he says on the same page 161 that the centre of the Earth is the centre of the Sun and the Moon, and indeed that their orbs are homocentric with the Earth, he alludes to his own hypothesis of the Sun and the Moon. For he explains their motions not by eccentric orbs, as Tycho did at least for the Sun, but by a single epicycle of the Sun carried by a concentric, and by two epicycles of the Moon — yet in such a way that the centre of the lunar orb is carried round the Earth on a small circle concentric with the Earth, as we have set out sufficiently in Book 3, on the Sun, chapter 19, and in Book 4, chapter 26, number 8, on the Moon.

[Margin: The system of Longomontanus is Semi-Tychonic.]

Although Longomontanus, then, follows Tycho in the fluidity of the heaven, in carrying the five lesser planets round the Sun and the Sun and the Moon round the Earth, and in the very order of the planets, he nevertheless dissents from him: both because he attributes a diurnal motion to the Earth and transfers to it the apparent motion of the fixed stars towards the east, and because for the Sun he uses an epicycle rather than an eccentric. It is therefore manifest that the system of Longomontanus ought to be called *Semi-Tychonic*, not Tychonic.

CAPVT IX.

Chapter IX.

De Syſtemate Noſtro.

On our own system.

[Margin: Summary of our system.]

I. After the various systems of the ancients and the moderns that rest on the immobility of the Earth, two at last seem to me more probable, after the Tychonic: one semi-Ptolemaic, the other semi-Tychonic, as regards the centre from which the eccentrici- ties of the orbs are to be measured. For as regards the order of the planets it is plainly Egyptian, and as regards the number of the heavens it differs from both. In it we place the Earth in the centre of the world, free from all motion, and around it the orb of the Moon, above which the circuit of the Sun turns in such a way that Mercury is nevertheless carried round the Sun, and Venus round Mercury, and they are found sometimes above the Sun, sometimes below it. Next, Mars encircles Venus in such a way that in opposition to the Sun it comes nearer to the Earth than the Sun does. Above Mars rises Jupiter, carrying round four satellites, which describe their epicycles about it; and above Jupiter, Saturn, he too attended by two companions, or attendants [lateronibus]. All of these are carried round obliquely by the Intelligences, freely, in a single heaven that is in fact fluid, along helical spirals, or in a screw-like course, with a single motion towards the west. Above Saturn is the solid sphere of the fixed stars, which, by a single spiral motion likewise, from one Intelligence or several, apparently exhibits a threefold motion: namely in longitude towards the west, in longitude towards the east, and in latitude on account of the variation of declination — a motion which is nevertheless in reality single, towards the west. Above the sphere of the fixed stars is the watery or crystalline heaven, for the use that is known to God; and above that the immobile Empyrean, flashing with admirable splendour, the most happy and everlasting dwelling of the Blessed.

We shall bring the arguments for the immobility of the Earth in the following section. For the solidity of the heaven containing the fixed stars, and for the fluidity of the planetary heaven, I have already brought them in section 1, chapters 3 and 7; for the number of the heavens being five, the air included, see what was said in section 3, chapter 1; and for the Intelligences that move the heaven, section 2, chapter 1. Further, for the order of the planets, see what I said in Book 7, section 1, chapter 4; and for the ascent and descent of the planets, Book 7, section 6, chapter 1. Again, for the exclusion of different orbs or circles, and for the single spiral motion, see what we said in this book, section 2, chapter 3, scholium 4, and in Book 6, chapter 18. Finally, for the approach of Mars to the Earth, see what was said in Book 7, section 2, chapter 3, scholium 4, and section 6, chapter 4, scholia 3, 4 and 5, and chapter 10, scholium 1. But if, as some would prefer, a distinct heaven must be given to the new stars between

the planetary heaven and that of the fixed stars; and if a heaven of their own must be assigned separately to the planets that have their companions, and the watery heaven is reduced to the Empyrean, there will be 6 heavens and 7 great bodies of the world, according to the economy set out in Book 7, section 6, chapter 4, scholium 5.

[Margin: The first form of the new system.]

II. These things being laid down as general elements of the world system, the first form is Semi-Ptolemaic: namely, the one which uses the centre of the Earth as the term from which it measures the eccentricities of the orbs, but in such a way that it describes the epicycles of Venus and Mercury about the Sun, and supposes the eccentricities of five or at least four planets, and indeed the epicycles too, to be not always of the same quantity, according to the hypotheses already explained in Book 7, section 2, chapter 6, and section 3, chapter 6. For this form, indeed, the figure of the Egyptian system set out in chapter 4 could serve, if Mars in opposition to the Sun came nearer to the Earth than the Sun does.

[Margin: The later form of the system.]

The second form is the Semi-Tychonic: namely, the one which I devised formerly at Parma, while I was dictating a treatise on the heaven, having professed philosophy there — that the Sun should be the centre of the motions of Mercury, Venus and Mars, and the Earth the centre of the lunar motion and of the fixed stars, and also of the motions of Saturn and Jupiter. I was driven to this by the following reasons. *First*, because I saw that Saturn and Jupiter had their own planets about them, but Mars, Venus and Mercury none; I therefore thought it probable that Saturn and Jupiter exercise their own monarchy in the heaven and are not satellites of the Sun, but that Mars is the greatest satellite of the Sun, inasmuch as it embraces the Earth in its circuit, while Venus and Mercury are the inner and nearer attendants of the Sun. *Second*, because I saw in the variation of eccentricity a greater connection of Mars, Venus and Mercury with the Sun than of Saturn and Jupiter. *Third*, because I judged that Saturn and Jupiter, as the slower and heavier planets, have a greater affinity with the very slow sphere of the fixed stars, and therefore with the centre of the Earth, since the fixed stars too look to the Earth rather than to the Sun in their motion. *Fourth*, because, since Mars, like Venus and Mercury, enters the heaven of the Sun as regards designation, it seemed far more likely that these three have the Sun as the centre of their motion, and that distinct regions of the aether are not to be distributed to them, but a single one, whereas distinct realms are to be ascribed to Jupiter and Saturn; and so a confusion of the heavens is avoided, even of heavens distinguished only by designation. I see that this inclusion of Mars, Venus and Mercury in the single heaven of the Sun found favour with Amicus, *De caelo*, page 285, and with Oviedus, in the single controversy *De caelo*, page 468. Therefore, if we wish to divide the visible heaven into several regions, we could distribute the first to the fixed stars, the second to Saturn, the third to Jupiter, the fourth to the Sun together with Mars, Venus

and Mercury, and the fifth to the Moon. *Fifth*, it is very probable that there is found among the planets one that is intermediate between the superior and the inferior planets and that has in its motions many things in common with Saturn and Jupiter and many also with Venus and Mercury: namely Mars. All of this, once more observations have been collected and weighed in volume 3, will be subjected to examination, so that it may be established whether this form satisfies the phenomena. Meanwhile let no astronomer take it ill that it is reviewed by us in this place among the other systems. The scheme of this system, as regards the visible heavens, is given below; for around it must be understood the watery or crystalline heaven, and around that the Empyrean.

V. Our system.

Diagram. A woodcut in the right column showing Riccioli's own system. An outer double circle, studded with small star sorts, encloses the whole; at the centre is a dark disc, the Earth, which carries no sign, with a small dot standing to its left. Near the top stand the sign of Saturn beside a small double circle and, below it, the sign of Jupiter beside a set of small concentric circles; below these the sign of Mars stands on a large circle. Lower down, the sign of Venus and a smaller sign stand above a rayed disc drawn with a face, the Sun. A crescent stands just above the Earth, and the sign of Mars again below the Earth. Two large circles, one about the Sun and one passing through the lower sign of Mars, intersect.

- Top, beside a small double circle: ♄ Saturn
- Below it, beside small concentric circles: ♃ Jupiter
- On a large circle below them: ♂ Mars
- Above the Sun: ♀ Venus
- Just above the Sun, below Venus: [?]
- Centre of the small circles: ☉ Sun (a rayed disc with a face)
- Just above the Earth: ☾ Moon
- Below the Earth: ♂ Mars

[Margin: On the interval and thickness of the primary heavens.]

III. It is further to be noted that in this system of ours the intervals are not so constructed that the lowest part of Saturn's concave heaven touches the highest part of Jupiter's convex one, or the lowest of Jupiter the highest of Mars, and so on, as happens in the Ptolemaic hypothesis; rather, some interval is left empty of stars between the fixed stars and the highest point of Saturn, namely of at least 9824 semidiameters of the Earth, and between the lowest point of Saturn and the highest of Jupiter an interval of 10,045 semidiameters of the Earth. Between the lowest point of Jupiter and the highest of Mars the interval is 5310 semidiameters of the Earth; and between the lowest point of Venus and the highest of the Moon, 1850. Further, the thickness of the whole heaven of Saturn, its satellites included, is 32,454 semidiameters of the Earth; that of Jupiter, its satellites included, is 21,361; that of the Sun, Mars, Venus and Mercury, taken as a single heaven, is 19,091 semidiameters of the Earth. Therefore the thicknesses of the heavens of these three monarchs with their

satellites stand in such proportion that, of units of which Saturn has 32, Jupiter has 21 and the Sun with its three satellites 19; while the interval between Saturn and Jupiter has 10, and that between Jupiter and Mars, and so on, 5. But you have more on these measures at the end of Book 7, arranged in their tables.

SECTIO QVARTA

Section Four

DE SYSTEMATE TERRÆ MOTÆ.

On the system of the moving Earth.

CAPVT I.

Chapter I.

De Tractationis huius Dignitate ac Neceſſitate. Deque Authoribus, qui hoc Syſtema Propugnandum aut Oppugnandum ſuſceperunt.

On the dignity and necessity of this treatment; and on the authors who have undertaken to defend or to attack this system.

[Margin: On the dignity of this subject.]

I. We now at last approach the controversy that is by far the most celebrated among astronomical controversies, especially in this century, and that, by the nobility of its subject, is supremely suited to rousing minds and sharpening judgements. So Seneca, in Book 7 of the *Natural Questions*, chapter 2, having raised the question why comets, if they consist of thin matter, last so long and are not dispersed by the diurnal turning of the heaven, in these words: *But if they are nothing other than pure fire, and remain for six months at a time, and neither the turning of the world nor its speed dissolves them, those others too can consist of thin matter and yet not be shaken apart on that account by the unceasing revolution of the heaven* — rightly and most shrewdly observed that another question, most worthy of contemplation, bears on the solution of this one, the question of the motion of the Earth; and he at once added: *It will also be relevant to this to have examined whether the world goes round while the Earth stands still, or whether the Earth turns while the world stands still. For there have been those who said that it is we whom the nature of things carries along without our knowing it, and that risings and settings do not come about by the motion of the heaven, but that we ourselves rise and set. It is a matter worthy of contemplation, that we may know in what state of things we are — whether the seat we have been allotted is the most sluggish or the swiftest; whether God moves all things around us, or moves us.* Nothing more excellent than these words could have been said of the excellence of this treatment.

II. Moreover, the necessity of settling this controversy is laid upon us — chiefly in view of the subject of the work we have undertaken — by the two

supreme governors and arbiters of our intellect, REASON and AUTHORITY. For, to touch briefly on Reason: nowhere has astronomy, which is subordinate to mathematics and to physics, clashed more sharply with the rest of physics than on the occasion of this controversy. On this side, the Philolaics, the Aristarcheans and the Copernicans have armed arguments drawn from every kind of phenomena, ancient and recent, against the constancy and stability of the Earth; on that side, the Peripatetics, and indeed almost all the natural philosophers, have summoned from every quarter the forces and remarkable properties of the elements to fortify and defend the citadel of the Earth. The former, so that they might secure victory and triumph more freely for the novelty of their hypothesis, have also contrived a new physics of the motion of the elements and of elementary bodies; the latter, on the contrary, have built upon the most ancient foundation of Nature a new mass of more solid reasons against these novel assaults — so that it now seems to be no longer astronomers and philosophers contending with one another, nor those fabled gods with the Giants, but the heavens themselves with the elements. Reasons have been devised on both sides of such subtlety at times, and stratagems of sophisms or paralogisms dressed in such an appearance of truth, that they can deceive even the most cautious, unless he examines himself and them again and again. So it is not at all surprising that not only those lightly imbued with the principles of astronomy, but even men otherwise most expert in this sublime science, have not penetrated to the depth of the Copernican hypothesis, and have repelled its falsity not with necessary reasons but with arguments lighter than was fitting. As a result, the spirits of that sect were raised, and it dared to sing that triumphal "Io" everywhere throughout Germany, England, France, and even Italy itself, and to reproach philosophers and some theologians with ignorance of the celestial and the terrestrial revolutions alike.

III. But these things might perhaps be tolerable, had these disagreements not gone so far at last as to bring into danger the authority — I do not say of Vesta or of the Vestal priests, but of the Catholic Church in defining controversies of this kind, and indeed even of Sacred Scripture. For if we grant the Copernicans the licence they have assumed for themselves of interpreting the divine Scriptures and evading the decrees of the Church, that licence will perhaps not be contained within the bounds of astronomy alone, or of natural philosophy, but could be extended by others to other, more sacred dogmas as well — if, that is, it were once permitted to deny the literal sense of the divine book without manifest necessity. That there is no necessity of departing from it, whether from the principles of astronomy or from those of physics, we shall have to show hereafter, however much ingenuity and artifice the hypothesis of the moving Earth may display. Before I set about doing this, I think the principal authors should first be reviewed: both those who have written for the suppositions of Copernicus and those who have written against them, and whose works have so far come into my hands — besides those who have built their own opinions on this hypothesis, taken as already supposed.

Authores pro Copernici Hypotheſi.

Authors for the Copernican hypothesis.

IV. Copernicus [Margin: Copernicus.] himself, in the letter to Paul III, and in Book 1 of the *De revolutionibus* from chapter 5 to chapter 11, Book 3 from chapter 3, and Book 5, chapters 2 and 3. Georgius Ioachimus Rheticus [Georg Joachim Rheticus] [Margin: Rheticus.], in the *Narratio prima* on the books of the *De revolutionibus* of his teacher Copernicus, with the preface and additions of Mästlin [Margin: Mästlin.]. Johannes Kepler [Margin: Kepler.], in the *Prodromus*, or *Mysterium Cosmographicum*, with the appendix of Michael Mästlin to the same *Prodromus*; in the book *De stella nova*, chapters 15 and 16; in the introduction to the *Commentaries on Mars*; and in the *Epitome of Copernican Astronomy*, especially Book 1, part 3, and the whole of Book 4. Christophorus Rothmannus [Christoph Rothmann] [Margin: Rothmann, formerly.], in his letters to Tycho, especially that of 1590 April 18, which is found on page 284 — although he afterwards gave way to Tycho, as Tycho reports in the *Epistolae Astronomicae*, page 92. Galilaeus de Galilaeis [Galileo Galilei] [Margin: Galileo.], in the four dialogues on the two chief systems of the world, the Ptolemaic and the Copernican, published first in Italian in the year 1632 but afterwards rendered into Latin and published at Lyon in the year 1641; where, although he professes to set out the reasons on both sides without deciding [indefinitè], he nevertheless concludes absolutely that, if one must stand by reasons alone, one must adhere to the Copernican hypothesis. Gulielmus Gilbertus [William Gilbert] [Margin: Gilbert.], in Book 6 of *De magnete* — an assertor, however, of the diurnal motion only. Paulus Antonius Foscarinus [Paolo Antonio Foscarini] [Margin: Foscarini.], a Carmelite, in the letter to Sebastianus Fantonus [Sebastiano Fantoni], the General, on the mobility of the Earth and the stability of the Sun, which David Lotaeus rendered into Latin. Didacus Stunica [Diego de Zúñiga] [Margin: Zúñiga.], in the *Commentaries on Job*. The *Aristarchus redivivus*, published at Paris with the author's name suppressed; the *Philolaus*, published in the same place in the year 1634, whose author Ismaël Boulliau [Margin: Boulliau.] declares himself to be in his *Astronomia Philolaica*, Book 1. Iacobus Lansbergius [Jacob van Lansbergen] [Margin: Lansbergen.], in the *Apologia* for the *Commentationes* of Philips van Lansbergen on the diurnal and annual motion of the Earth, against the *Vesta*, or *Anti-Aristarchus*, of Libertus Fromondus [Libert Froidmont] and against Io. Baptista Morinus [Jean-Baptiste Morin]. Pierre Hérigone [Margin: Hérigone.], in volume 5 of the *Cursus Mathematicus*, Book 2 of the Theorics; and Pierre Gassendi [Margin: Gassendi, formerly.], both in the *Institutio Astronomica*, Book 3, and in two letters, but chiefly the second, *De motu impresso a motore translato*, at the end of which, however, he submitted his intellect captive to the decrees of the Church. Descartes [Margin: Descartes.], too, inclines to this opinion in part 3 of the *Principles of Philosophy*.

Auctores qui contra Hypotheſim Terræ Motæ ſcripſerunt.

Authors who have written against the hypothesis of the moving Earth.

V. Aristotle [Margin: Aristotle], in Book 2 of the *De caelo*, from chapter 12, or from text 71, and again from text 96; and there Simplicius, Philalthaeus, the Conimbricenses, Ruvius and very many other Peripatetics. Ptolemy [Margin: Ptolemy.], in Book 1 of the *Almagest*, chapters 5 and 7; and there Theon of Alexandria [Margin: Theon.]; and Regiomontanus [Margin: Regiomontanus.] in the *Epitome of the Almagest*, Book 1, conclusions 3 and 5. Alfraganus [Margin: Alfraganus.], difference 4. Macrobius [Margin: Macrobius], Book 1 on the *Dream of Scipio*, chapter 22. Cleomedes [Margin: Cleomedes], Book 1 of the *Cyclic Theory*, chapter 9. Petrus Aliacensis [Margin: Aliacensis], question 3 on the *Sphere*. Georgius Bucanhanus [George Buchanan] [Margin: Buchanan.], Book 1 of the *Sphere* set out in verse. Maurolico [Margin: Maurolico], dialogue 1 of the *Cosmographia*, from page 9. Clavius [Margin: Clavius.], in the *Sphere*, from pages 143 and 195. Barocius [Margin: Barocius.], Book 1 of the *Cosmographia*, page 33. Michaël Neander [Michael Neander] [Margin: Neander.], in the *Elements of Astronomy*, page 40. Telesius [Bernardino Telesio] [Margin: Telesius.], Book 2 *De caelo*. Martinengus [Margin: Martinengus.] in the *Glossa magna*, from page 320. Iustus Lipsius [Justus Lipsius] [Margin: Lipsius.], Book 2 of the *Physiologia*, dissertation 19. Christoph Scheiner [Margin: Scheiner], in the *Disquisitiones mathematicae*, from number 13. Tycho [Margin: Tycho.], in the *Epistolae Astronomicae*, pages 129, 147, 149, 157, 166, 185 and 188; in volume 1, the *Progymnasmata*, pages 406, 549, 658, 660 and 684; and in volume 2, chapter 8. Alexander Tassonus [Alessandro Tassoni] [Margin: Tassoni.], Book 4 of the *Diversarum cont.*, question 25. Scipio Claramontius [Scipione Chiaramonti] [Margin: Chiaramonti.], in the *Antiphilolaus*, and in the *Defensio Antitychonis* against the author of the two systems, namely Galileo. Melchior Incofer [Melchior Inchofer] [Margin: Inchofer.], in the *Tractatus syllepticus*. Libertus Fromondus [Margin: Froidmont], in his *Vesta*. Iacobus Acarisius [Giacomo Accarisio], Bishop of Vieste, in the fourth lecture, on the rest of the Earth and the motion of the Sun. Iulius Caesar Lagalla [Giulio Cesare Lagalla] [Margin: Lagalla.], *De phaenomenis in orbe Lunae*, chapter 7. Adam Tanner [Margin: Tanner.], *De caelo*, question 9, and volume 1 of the *Theologia*, disputation 6, question 4, doubt 3. Bartholomaeus Amicus [Margin: Amicus.], *De caelo*, from page 284. Antonius Rocco [Antonio Rocco] [Margin: Rocco.], in philosophical exercitations 6 and 7. Marinus Mersennius [Marin Mersenne] [Margin: Mercurius.][34], on chapter 1 of Genesis. Georgius Polaccus [Margin: Polaccus.], in the *Anticopernicus*. Athanasius Kircher [Margin: Kircher.], in the *Magnes*, from pages 539 and 581. David Spinellus [Margin: Spinellus.], in his *Jupiter among the Ethiopians*. Io. Pineda [Juan de Pineda] [Margin: Pineda.] and Io. Lorinus [Jean Lorin] [Margin: Lorinus.], on chapter 1 of Ecclesiastes.

[34]the margin note against Mersenne's name is printed "Mercuri⁹" (Mercurius).

Bartholomaeus Mastrius [Margin: Mastrius.] and Bonaventura Bellutus [Margin: Bellutus.], disputation 1 *De caelo*, question 2 and question 4, article 3. Io. Poncius [John Punch] [Margin: Punch.], disputation 22 of the *Physics*, question 9. Io. Antonius Delphinus [Margin: Delphinus], *De globis caelestibus*, chapter 18. Io. Elephantutius [Margin: Elephantutius.], in the *Universi orbis structura*. Those, however, who contended against that hypothesis at greater length were Tycho, Chiaramonti, Scheiner, Froidmont, Tassoni, Inchofer and Polaccus.

CAPVT II.

Chapter II.

De Auctoribus, qui Diurnam Vertiginem Terræ circa ſuum centrum & axem attribuerunt.

On the authors who have attributed a diurnal rotation to the Earth about its own centre and axis.

I. The diurnal revolution, completed in 24 hours, by which all the stars, whether fixed or wandering, are seen to be carried round from the east through the south into the west, and to return from there to the east through the midnight point — this, the most ancient authors once asserted, appears indeed in the stars, but in reality comes about through the motion of our Earth, turned about its own centre and axis toward the east and going round to meet the stars themselves. Copernicus speaks of these authors in Book 1, chapter 5, as follows: *Of this opinion, indeed, were Heraclides and Ecphantus the Pythagoreans, and Nicetas of Syracuse in Cicero, who turned the earth in the middle of the world. For they thought that the stars set by the interposition of the earth, and rose when it gave way.* He does not, however, indicate the sources from which he drew these things; but they are, of course, these. Cicero, in Book 2 of the *Academic Questions*, after saying: *Do you not also say that there are people over against us on the opposite side of the earth, who stand with their footprints set against ours, whom you call Antipodes? Why are you angrier with me, who do not scorn these things, than with those who, when they hear them, think you out of your minds?* — at once added: *Nicetas of Syracuse, as Theophrastus says, holds that the heaven, the Sun, the Moon, the stars — in short all things above — stand still, and that nothing in the world moves besides the earth; and since it turns and twists itself about its axis with the greatest speed, all the same effects are produced as would be if the heaven moved while the earth stood still. And some think that Plato too says this in the Timaeus, but rather obscurely.* About Plato, however, we shall inquire a little below. Again, Cicero likewise, in Book 1 of the *Tusculan Questions*: *Nicetas of Syracuse was the first to hold that the Earth moves.* And in Book 3 of the *De placitis philosophorum*, chapter 13, Plutarch reports the following: *Heraclides Ponticus and Ecphantus the Pythagorean do indeed move the earth, but by no means from place to place; rather, like a wheel resting on its axle, it turns about it from west to east. Democritus holds that from the very beginning it wandered widely, both because it was small and because*

it was light; but that as time went on it grew dense and came to rest, balanced by its own mass. And in chapter 17: *Seleucus the mathematician, who himself also moves the earth, says that the revolution of the Moon runs counter to its rotation and motion; and that by this impulse, as the wind gathers itself between these bodies and rushes into the Atlantic, the seas are, as is probable, thrown into turmoil.* That Plato was once of this same opinion we have already heard above from Cicero; but a much more ancient witness, Aristotle, seems to have said the same, in Book 2 of the *De caelo*, text 75: *But some say*, he says, *that it, though lying at the centre*, namely the Earth, *rotates and moves about the pole that is always immobile, as is written in the Timaeus.* And this is how Rheticus, in his *Narratio prima*, Gassendi in Epistle 2, *De motu impresso*, and others understand Plato.

[Margin: The opinion of Heraclides, Ecphantus, Democritus and Seleucus.]

[Margin: The opinion of Nicetas.]

II. Yet when I read Plato's *Timaeus* through, I could never be persuaded that this opinion of the rotation of the earth was Platonic, since Plato speaks in the person of Timaeus. For in that dialogue the first part in discussing the generation of the world and of its parts is assigned to Timaeus by Critias, with Socrates' consent. Critias had said: *Consider, Socrates, whether we have arranged the return banquet for you suitably. It seemed good to us that Timaeus, as the most expert of us all in astronomy, and the most versed in learning the nature of things, should speak first, so that, beginning from the generation of the world, he should come down to the nature of the human race*, etc. And a little after, Socrates replies: *You seem to me to have prepared an abundant and splendid table of discourse; it is therefore your office, O Timaeus*, etc. Timaeus, then, beginning from the generation of the world and setting out the intervals of the eight spheres according to harmonic proportions, recognizes two motions in the heaven: one outer, from east to west, which he attributes to the outermost sphere and not to the Earth; the other inner, from west to east, which he ascribes to the seven spheres of the planets. His words about God are these: *He made one of the circles outer, the other inner. The outer motion he named that of the Same nature, the inner that of the Other; and the one that was akin to the nature of the Same he bent sideways to the right, namely to the west, but the one of the Other diagonally to the left; and he gave the sovereignty to the motion that was alike and of the same nature. This alone he left undivided*, that is, simple and uniform. *But the inner, when he had divided it six times and made seven unequal orbs at double and triple intervals — each of them being three, that is, endowed with three motions: lengthwise to the right, lengthwise to the left, and in latitude toward the poles of the world — he ordered the orbs to travel in courses contrary to one another; and of the seven inner ones, he ordered three to turn with equal speed, namely the Sun, Mercury and Venus, and four with a speed unequal both to one another and to the other three, yet duly measured.* And after a few intervening words he follows the same motions further, saying: *When God had made the bodies of such stars, seven in number, he applied them to seven orbs, which revolve in the circuit of the Other and diverse nature. The Moon he placed in the first circuit above the earth, the Sun in the second. Then the globe of*

Lucifer and the star said to be sacred to Mercury he fixed in circles equal to the Sun in speed but with a power contrary to it; and so it comes about that these stars — the Sun, Lucifer and Mercury — overtake one another and are overtaken by one another in turn. If anyone should wish to run through the orders, progressions and reasons of the other stars in full, it will be more than the work itself which is undertaken for the work's sake. And presently, setting out how the planets, by their oblique motion through the zodiac, are seen to be carried with a motion contrary to that of the eighth sphere, he says: *They kept this course, namely, that according to the oblique motion of the Other and diverse nature, subordinated to the motion that is uniform and of like nature,*

[Margin: The genuine opinion of Timaeus and Plato.]

those orbs traverse partly a wider, partly a narrower circle, and those with the smaller circle revolve more swiftly, those with the larger more slowly. But according to that common and uniform motion itself, those that run through it most swiftly seem, while overtaking, to be overtaken by the slower. For that supernal rotation, turning all their circles round with a varied circuit — because they are driven by two contrary motions at once — showed as nearest to itself the one that falls back from it most slowly, swiftest as it is: namely Saturn. And so that there might be a most certain measure of their speed and slowness, and the dance of all eight motions might come forth into the light, God kindled a most brilliant light in the second circle from the earth, which we now call the Sun.

Could Timaeus, and so Plato, have declared his mind to us in clearer words as to what we are asking — namely, whether the apparent motion of the primum mobile is accomplished by the rotation of the earth, the lowest globe, or rather by the eighth circle, the outermost of all? Not at all, I say. But neither in the *Epinomis* does Plato recognize any other proper motion in the eighth sphere, but only the common one toward the west. Therefore, if he had ascribed this motion to the Earth, he would not have described for us a simple motion, and one of the same nature, in the eighth sphere, nor would he have called the motion of the planets contrary to it. But why say more? Did not the same Timaeus — that is, Plato speaking in the person of Timaeus — when he had undertaken to distribute the five regular bodies to the heaven and the elements, say in the plainest words: *Let us assign the cubic form to the Earth; for of all four the earth is the most immobile, and the most compacted of all bodies, and that must necessarily become such which possesses the firmest and safest bases.* [Margin: Timaeus assigns the cube to the Earth.] And therefore Plutarch, in Book 2 of the *De placitis*, chapter 6, reporting Pythagoras' opinion on attributing the cube to the Earth, said: *Plato in all these things Pythagorizes.* From this, perhaps, came the rite by which the cube was the symbol of the motionless earth, and priests sacrificed seated to Ops, that is, to the resting earth. Accordingly Marsilius Ficinus, certainly most expert in Platonic doctrines, in the *Compendium on the Timaeus*, chapter 25, lays down that in Plato's view the Earth is immobile.

But from where, you will ask, did that suspicion arise of a motion of the earth asserted by Timaeus or, as Cicero says, indicated somewhat obscurely?

I should think, from these words: *He willed the Earth, our nurse, bound about the pole stretched through the universe, to be the maker and guardian of day and night, and also the first and most ancient of all the gods*, etc.; *but the dances of these gods, and their meetings among themselves*, etc. By these last words, however, he does not place among the mobile gods the earth — which a little later he lays down as sitting motionless on the cube — but the souls and intelligences of the heavenly bodies. Nor does he call it the maker of day and night on the ground that by its own turning it goes to meet the Sun, but because, casting by its opacity a shadow into the part opposite the Sun, it makes night in that hemisphere of itself. And perhaps Aristotle, in that text 75 of the second book of the *De caelo*, adduces Timaeus not for the motion of the earth but for the immobility of the axis and pole about which others said it moved. What Cicero attributes to Timaeus therefore still remains in doubt, and it is far more probable that neither Timaeus nor Plato, in this passage at least, gave any motion to the Earth. Laertius must therefore be corrected, who in Book 3, in the life of Plato, having misunderstood the passage of Timaeus already mentioned, says of Plato's opinion: *That the Earth is the most ancient of all the gods there were in heaven; that it was made so as to vary the times and alternations of day and night; and that, being in the middle, it moves about the middle.*

III. Besides the ancients, however, not a few of the more recent writers have attributed to the Earth this single motion — not, that is, the motion τῆς φορᾶς [Greek: tēs phoras, "of carrying"], that is, of translation, but τῆς δινήσεως [Greek: tēs dinēseōs, "of whirling"], that is, of spinning, or diurnal rotation. Nicolaus Cusanus [Margin: The opinion of Nicolaus Cusanus.], the Cardinal, in Book 2 of the *De docta ignorantia*, chapter 11, where he says: *The earth, therefore, which cannot be the centre, cannot lack all motion.* And again: *From these things it is evident that the earth moves; and since from the motion of the comet we have learned by experience that the elements of air and fire move, and that the Moon moves less from east to west than Mercury or Venus, or the Sun, and so by degrees: hence the earth itself moves still less than all.* And after a few words: *Although the earth, as a star, is nearer to the central pole, yet it moves, and does not describe the smallest circle in its motion.* And in chapter 12: *The ancients did not reach these things now said, because they fell short in learned ignorance. It is now evident to us that this earth truly moves, although this does not appear to us, since we do not apprehend motion except by a certain comparison with something fixed. For if someone did not know that water flows, and did not see the banks, how, being on a ship in the middle of the water, would he apprehend that the ship moves? And for this reason, since it would always seem to anyone, whether he were on the earth or in the Sun or in another star, that he himself is at a centre, as though immobile, and that all other things move, he would certainly always set up for himself one set of poles after another: being in the Sun, some; on the earth, others; others in the Moon, and in Mars, and so for the rest. Hence the machine of the world will be as though having its centre everywhere and its circumference nowhere; for its circumference and centre is GOD, who is everywhere and nowhere.*

This author nevertheless seems, in these same passages, to attribute to the Earth some motion of translation as well; but elsewhere — in Book 7 of the *Exercitationes*, in the sermon that begins *Debitores sumus* — he seems either, forgetful of himself, to contradict himself, or to have come to a better view, where he says [Margin: A sounder opinion of the same author.]: *For prayer is more powerful than all creatures: for the Angels, or Intelligences, move the orb, the Sun, the stars; but prayer is more powerful, because it stops motion, just as the prayer of Joshua made the Sun stand still.* From him, however, Copernicus seems to have taken the simile of people on a ship, and from it the argument for the diurnal motion of the earth. In Book 1, chapter 5, he had said [Margin: The opinion of Copernicus.]: *Although it is generally agreed among authors that the earth rests in the middle of the world, so that they think it inconceivable, and even ridiculous, to hold the contrary, yet if we consider the matter more attentively, this question will be seen to be not yet settled, and therefore by no means to be despised. For every change of place that is seen comes about either through the motion of the thing observed, or of the observer, or certainly through an unequal change of both; for between things moved equally in the same direction no motion is perceived — between the thing seen, I mean, and the one seeing. But it is from the Earth that that celestial circuit is viewed and reproduced to our sight. If, then, some motion is assigned to the earth, it will appear in all things that are outside, but toward the opposite part, as though they were passing by; and such, first of all, is the daily revolution.* Afterwards, in chapter 8, from the argument drawn from the earth's spherical shape, which is most apt for motion, he flies off altogether into the opinion of Nicetas, and says: *Whether, then, the world is finite or infinite, let us leave to the dispute of the natural philosophers, holding this as certain: that the earth, enclosed by its poles, is bounded by a globular surface. Why then do we still hesitate to grant it the mobility that nature has made fitting to its form, rather than that the whole world, whose limit is unknown and cannot be known, should glide round? And why should we not admit that the appearance of the daily revolution is in the heaven, and its truth in the earth?* Copernicus, therefore, asserted this motion of the earth not merely by way of doubt, or speaking hypothetically, but absolutely [Margin: Copernicus affirms the motion of the Earth not merely hypothetically but absolutely.], and tried to confirm it with many arguments throughout that chapter 8 — arguments which we shall set out and refute below. And so he concludes that chapter by saying: *You see, then, that from all these things the mobility of the earth is more probable than its rest, especially in the daily revolution, as being most proper to the earth.*

IV. Next, as regards the diurnal motion of the earth, William Gilbert, physician of London, subscribed to Copernicus, in his new physiology *De magnete magneticisque corporibus*, Book 6, chapter 3, where, having praised Heraclides Ponticus, Ecphantus, Nicetas, Aristarchus, Philolaus and Copernicus, he says: *It is therefore an old opinion, handed down from ancient times, but now augmented by great thoughts, that the earth is carried round whole by a diurnal revolution in the space of 24 hours.* And below he concludes: *And so we are carried by the*

diurnal rotation of the earth (a motion, that is, more fitting), and as a boat moves upon the waters, so we are turned round with the earth, and yet we seem to ourselves to stand still and be at rest. He then contends, in chapter 4, that this motion comes about from the magnetic virtue of the earth; in chapter 5 he refutes, or tries to refute, the reasons of those who deny the motion of the earth; and in chapter 6 he ascribes the cause of the definite time of 24 hours in which this revolution is accomplished to a magnetic alliance of the Earth and the Moon, these globes being driven forward by the Sun in proportion to their orbs. Finally, Copernicus and Gilbert were followed in this by David Origanus, in volume 1 of the *Ephemerides*, in the dedicatory epistle; by Christianus Severini Longomontanus, in the *Astronomia Danica*, Book 1 of the Theorics, chapters 1 and 4; and by Andrea Argoli, in the *Pandosion sphaericum*, chapter 3 [Margin: Origanus, Longomontanus and Argoli, assertors of the diurnal motion of the Earth.]. Not, however, by Tycho, whatever some have imagined; those people, however, we have refuted sufficiently in Section 3, chapter 8, number 4. Besides these, moreover, all those who attributed an an- nual motion to the Earth also freely granted it the diurnal one; we shall review them in the following chapter. And although Seneca, taking occasion from the diurnal motion of comets, raised a doubt about this motion of the earth in particular, as is clear from his words quoted in this Section at the beginning of chapter 1, the same author nevertheless, in the book *De providentia*, chapter 1, followed the sound and common opinion and said [Margin: Seneca, an assertor of the stability of the Earth.]: *That this order is not the work of wandering matter, and that things which came together at random do not hang with such art that the heaviest weight of the lands sits motionless and feels the flight of the heaven hastening round it.*

CAPVT III.

Chapter III.

De Auctoribus, qui præter Diurnam Vertiginem, Annuam quoq. tranſlationem Telluri adſcripſerunt. Vbi obiter de Veſta, fueritne Terra an Ignis.

On the authors who, besides the diurnal rotation, also ascribed an annual translation to the Earth. Where, in passing, on Vesta: whether she was Earth or Fire.

I. At this point I am pleased to borrow that saying of Pliny's [Margin: Pliny, Book 2, chapter 23.]: *It is wonderful how far the shamelessness of the human heart goes, invited on by some tiny success.* The Pythagoreans had seen that one of their own sect, namely Ecphantus, had successfully represented by a diurnal motion of the earth the same phenomena that others had accounted for by a diurnal revolution of the stars. From there, therefore, taking a step further and with greater daring, they added to it an annual translation as well, which is commonly ascribed to the Sun, placing the Sun, as the fount, so to speak, of heat and light, immobile at the centre of the universe. The first of them, I find,

was Philolaus, of whom Plutarch, in Book 3 of the *De placitis philosophorum*, chapter 11, reports the following [Margin: Opinions of Philolaus on the Earth.]: *The followers of Thales said the Earth is in the middle. Xenophanes, that it is first fibred down into the infinite. Philolaus the Pythagorean, that fire is in the middle, being the hearth of the universe; second, the antichthon, that is, the earth of the Antipodes; third, the one we inhabit, which is both set opposite the antichthon and turns round it — which is the reason why those who live on that one are not seen by us.* And in chapter 13: *The others said that the earth stays still; but Philolaus the Pythagorean, that it turns about the fire in an oblique circle, like the Sun and the Moon.* Diogenes Laërtius, in the life of Philolaus, agrees with Plutarch, but indicates only the motion of the primum mobile: *He holds that all things come about by harmony and necessity; he says that the Earth moves according to the first circle; others affirm that it was Nicetas of Syracuse who held this.* From these things one better understands what Aristotle relates in Book 2 of the *De caelo*, text 72, in these words: *While most of those who say that the whole heaven is finite say that the earth lies in the middle, those who live around Italy, and are called Pythagoreans, say the contrary. For they say that fire is in the middle, and that the earth is one of the stars and, carried in a circle around the middle, makes night and day. Moreover they construct another earth opposite to this one, which they name* ἀντίχθονα [Greek: antichthona, "counter-earth"], *not fitting reasons and causes to the phenomena, but dragging the phenomena themselves toward certain opinions and reasons of their own.* Among these reasons he mentions in first place, in text 73, the one drawn from the dignity of place: namely, that the most honourable region befits the most honourable of bodies, and that fire, or the Sun, is nobler than the earth; and he adds: *Moreover the Pythagoreans, because it is most fitting that what is most principal in the Universe be guarded, and the middle is such, said that fire holds this region, which they call the prison, or guard-house, of Jove.*

II. Not only in Italy, however, but also in the island of Samos, from which we know that Pythagoras came, Aristarchus, himself a Samian, taught the same opinion on the motion of the Earth [Margin: The opinion of Aristarchus of Samos.], more than a hundred years after Philolaus; for it is gathered from Ptolemy, Book 3, chapter 2, that this Aristarchus flourished in year 44 from the death of Alexander the Great, that is, about the year 280 before Christ. Now Archimedes, in the *Arenarius* [*The Sand-Reckoner*], speaks of Aristarchus thus: *Aristarchus of Samos, refuting these things in what has been written by the astrologers* — namely, about the Earth resting in the middle of the world — *published certain hypotheses from which it follows that the world is many times the world just described. For he supposes that the fixed stars and the Sun remain immobile, but that the earth is carried round the Sun along the circumference of a circle which is set in the middle of the course; and that the sphere of the fixed stars, situated about the same centre as the Sun, is of such size that the circle in which he supposes the earth to be carried round has the same proportion to the distance of the fixed stars as the centre of a sphere has to its surface.* But Archimedes at once rejects this [Margin: Archimedes' censure

of Aristarchus.], saying: *But this is impossible; for since the centre of a sphere has no magnitude, it must not be supposed to have any ratio to the surface of the sphere either.*

With these words of Archimedes, what Plutarch says in the person of Lucius in the little work *De facie in orbe Lunae* agrees excellently. He speaks thus: *Come now, would you make us guilty of impiety, in the way that Cleanthes thought Aristarchus of Samos ought to have been indicted by the Greeks for violating religion, as if he had moved the Lares of the Universe, and Vesta, from their place — because that man, trying to save the phenomena of the heaven by certain reasonings, had supposed the heaven to be at rest, and the earth to be rolled round along an oblique circle and meanwhile to turn about its own axis.* [Margin: Cleanthes' censure of Aristarchus.] From this passage of Plutarch it came about that Kepler, fearing for himself the ecclesiastical censure raised against him by Chiaramonti for asserting the motion of the earth, said in the *Hyperaspistes*, Book 3, chapter 22, page 183: *The hypotheses that I follow — if he should seize the bolt of Jove and thunder; if he should bring a charge against me, as Cleanthes once did against Aristarchus, of violated religion because Vesta's sacred things were moved from their place — the astronomers will be abundantly satisfied by the equipollence demonstrated in the Commentaries on Mars, inculcated in the Harmonics, and used in this very booklet.*

III. But Plutarch now invites me to take this occasion to inquire what kind of deity Vesta was among the pagans, and in what place she stood — something bearing on this Pythagorean fiction about the place and motion of the Earth [Margin: Vesta: what and where?]. In this very question we shall find two opinions, arising, unless I am mistaken, from a twofold opinion about the place of the earth. For all held that Vesta rests at the centre of the world. So those who thought that the Earth sits at this centre also held that Tellus was the same as Vesta; whereas those who believed the centre of the Universe to be occupied by Fire or by the Sun likewise took Vesta to be perpetual and immobile fire. Of the first opinion were those who said she was the sister of Ceres and Juno, born of Rhea Ops and Saturn — as Apollodorus in Book 1 of the *Bibliotheca*, with whom Ovid agrees in the *Fasti*:

They record that Juno and Ceres were born of Ops, From Saturn's seed; the third was Vesta.

He also sings, in Book 1 of the *Metamorphoses*:

The earth stands by its own force; by standing with force it is called Vesta.

But before him, Plato in the *Phaedrus*, having said that eleven gods proceed following the chariot of Jupiter, their chorus-leader and leader of the dance, added, making an exception of Vesta [Margin: Plato's view of Vesta.]: μένει μὲν Εστία ἔν θεῶν οἴκω μόνη [Greek: menei men Estia en theōn oikō monē, "Hestia remains alone in the house of the gods"] — *for Vesta remains and stays alone in the house of the gods.* And again in Book 12 of the *Laws*: *Earth and Vesta are a sacred dwelling for all the gods.* To this point are those words of Arnobius, Book 3, *Against the Gentiles*: *Some declare the Earth to be Vesta, because it alone stands still in the world, its other parts being set in perpetual mobility.* Servius too, on

Book 1 of the *Aeneid*, thinks Vesta was so called because she is clothed [vestita] with various things; *for she herself*, he says, *is said to be the Earth.* Some Greeks too, as Lipsius notes in his book *De Vesta*, chapter 1, think Vesta was so called παρὰ το ἑστᾶναι ὅ ἐστιν ἐν ἑνὶ τόπω [Greek: para to hestanai ho estin en heni topō, "from standing, that is, being in one place"], because she remains in one place. And in Festus, some call her for this reason *Stata mater* [the Standing Mother]. Lipsius also adduces these lines of Pindar:

And Earth Mother, and by the wise You are surnamed Vesta, a seat in the very air.

Nor does it stand in the way that Fire too is attributed to Vesta. That can be understood of subterranean and perpetual fire, even though it exhales through various chasms, or of fire preserved in the earth and by the earth, as Servius notes, saying: *For Vesta is said to be the Earth, which no doubt has fire, as is given to be understood from Etna and Vulcan.* To this point are the words of Phurnutus [Cornutus] in Lipsius: *Because the fiery force that is in the world is nourished from here, and subsists through it; or because the fertile Earth is also the mother of animals, for whom the fiery force is the cause of life.* Or certainly, as Dionysius of Halicarnassus relates in Book 2 of the *Antiquities*, fire is sacred to Vesta, *because, since Vesta is the Earth and holds the middle place of the world, she kindles from herself the su- perior fires.* From this arose the opinion, which Martianus Capella indicates in Book 1 of *De nuptiis Philologiae*, that *Vesta was the nurse of Jupiter*. Others, however, take Vesta simply for living and perpetual Fire, according to that line of Ovid's:

And understand Vesta to be nothing other than living flame.

and of Virgil in the *Moretum*:

And while Vulcan and Vesta perform their parts,

And Cicero, Book 3 of *De legibus*: *And since Vesta, so called by a Greek name, has embraced, as it were, the hearth of the city*; and Book 2 of *De natura deorum*: *The name of Vesta is taken from the Greeks, for she is the one whom they call* Εστία [Greek: Estia, "Hestia"], *and her power pertains to altars and hearths.* For just as, by the addition of the letter V, *Er* became *Ver* and *Eneti* became *Veneti*, so *Esta* was called *Vesta*, as Servius notes on Book 1 of the *Aeneid*. But more to our point is Plutarch in the *Numa*: *Numa is said to have built round the perpetual fire, to guard it, a temple of Vesta of circular form — not to imitate the shape of the Earth, as though the Earth were Vesta, but the shape of this whole universe, at whose middle the Pythagoreans hold that Fire stands; and this they call Vesta, and the Unity. The Earth, on the other hand, they hold to be neither immobile nor set at the middle of the circuit, but suspended in an orb round the fire, and not to be reckoned among the excellent or first parts of the world. They would have it that Plato, when he was already old, thought the same of the Earth: that it is set in another place, and that the middle and most worthy region belongs to some other, more excellent body* [Margin: The opinion of Plato, when already old, on the place and motion of the earth.]. But so long as no passage from Plato is brought forward, I hold to the view that Plato always thought the earth immobile — on the strength of his own words in the *Phaedrus* and in Book 12 of the *Republic*, already cited,

and of the words of the *Timaeus* quoted in the preceding chapter, number 2. Granted that he came to Italy to see Pythagoras and Philolaus, and there came to know Timaeus of Locri and Archytas of Tarentum, as we have learned from Cicero, Book 1 of the *Tusculans*, and from Laertius. For this view I appeal from Plutarch to Plutarch, who says in the *De placitis philosophorum*, Book 2, chapter 6, that Plato, with Pythagoras, assigned the cube to the Earth on account of its immobility; in chapter 15, that he did not number it among the planets; and in Book 3, chapter 13, excepting Heraclides and Philolaus, he says: *The others said that the earth stays still.* I therefore do not agree with Gassendi, who in Letter 2, *De motu impresso*, asserts on the authority of Plutarch that Plato in his later years granted both motions to the Earth. Plutarch does not assert this; he reports the conjecture of others, when he says: *Some would have it.*

IV. The opinion of Philolaus and Aristarchus on this motion of the Earth had, however, fallen asleep: lulled into the deepest silence through many past centuries, it had lain in almost universal oblivion, when Nicolaus Cusanus, as I indicated in chapter 2, number 3, in a lowered voice, and the other Nicolaus, namely Copernicus, in a loud voice, roused it. Nor did Copernicus put forward this motion of the Earth as a mere hypothesis, as some think — above all Scipione Chiaramonti, in the preface to his *Antiphilolaus*, and before him the anonymous author who prefixed the notice to the reader to Copernicus's works. On the contrary, he asserted it absolutely, either as more probable or even as demonstrated [Margin: Copernicus asserts the motion of the Earth absolutely, and not only on a hypothesis.]. That is the sense of the words of Copernicus himself in his preface to Paul III, where he says: *Therefore, when I considered with myself how absurd an* ἀκρόαμα [Greek: akroama, "a thing heard", a doctrine] *those would think it who know that this opinion has been confirmed by the judgements of many centuries — that the Earth is placed immobile in the middle of the heaven, as its centre — if I, on the contrary, were to assert that the Earth moves, I hesitated for a long time whether I should bring to light my commentaries, written to demonstrate its motion, or whether it would be better to follow the example of the Pythagoreans and of certain others, who used to hand down the mysteries of philosophy not in writing but from hand to hand, and only to their relatives and friends, as the letter of Lysis to Hipparchus testifies.* Not much later he uses the word "demonstration" again, and says: *that the more absurd this doctrine of mine on the motion of the Earth now seemed to most people, the more admiration and gratitude it would win once they saw, through the publication of my commentaries, the fog of absurdity removed by the clearest demonstrations.* And again, repeating the same word, he says: *Nor do I doubt that ingenious and learned mathematicians will agree with me, if — as this philosophy above all demands — they are willing to learn and weigh, not superficially but thoroughly, what I bring forward in this work for the demonstration of these matters.* So firmly, indeed, did he set his mind on this view of both motions of the Earth that he even contrived to brand with rashness and calumny those who tried to assert the Earth's immobility from Sacred Scripture. For when he had said that he dedicated his work to Paul III, as one versed in mathematics, so

as not to seem to shun anyone's judgement, he added: *so that by your authority and judgement you may easily check the bites of slanderers, although the proverb says there is no remedy against the bite of a sycophant.* And soon after: *If perhaps there are* ματαιόλογοι [Greek: mataiologoi, "idle talkers"] *who, although ignorant of all mathematics, nevertheless take upon themselves to judge of these things, and who, on account of some passage of Scripture badly twisted to their purpose, dare to censure and attack this undertaking of mine, I do not care about them at all, so much so that I even despise their judgement as rash.* [Margin: Copernicus's arrogant pronouncement.] With such haughtiness, to be sure, did that man dare to rise up who a little earlier had seemed almost to dread the judgement of men.

But it must now be shown from his own words in what way he assigned the annual translation to the Earth, as to one of the planets, rather than to the Sun. Having begun chapter 9 of Book 1 of the *Revolutions* thus: *Since, therefore, nothing prevents the mobility of the earth, I think we must now see whether several motions also befit it, so that it may be considered one of the wandering stars*, he finally concludes: *If, therefore, the earth too makes other circuits, for example about the centre, they must be those which appear in like manner from outside in many bodies, among which we find the annual circuit. For if it is changed from a solar to a terrestrial one, immobility being granted to the Sun, the risings and settings of the signs and of the stars, by which they become morning and evening stars, will appear in the same way. The stations, retrogradations and progressions of the wandering stars, too, will be seen to be a motion not of theirs but of the earth, which they borrow for their appearances. Finally, the Sun itself will be thought to occupy the middle of the world. All this is taught us by the reason of the order in which those bodies succeed one another, and by the harmony of the whole world, if only we look at the matter itself with both eyes (as they say).* And when in chapter 10 he had related many things about this order, bearing on the various systems of the world, he added: *Accordingly we are not ashamed to confess that all this which the Moon encircles, together with the centre of the earth, passes through that great orb among the other wandering stars with an annual revolution about the Sun; that near it, namely the Sun, is the centre of the world; and that, the Sun also remaining immobile, whatever appears of the motion of the Sun is rather verified in the mobility of the earth.* [Margin: Copernicus places the Sun not in the very centre of the world, but round it, or near it.] In what way the annual motion of the Earth's centre about the centre of the world is combined with its diurnal revolution about its own centre, and indeed with a certain third motion of the earth's axis, which keeps its parallelism to the axis of the Equator, he explains at greater length in chapter 11, with a diagram attached — which we shall supply in the following chapter. In Book 5, chapters 1, 2 and 3, moreover, he teaches how the annual motion of the earth's centre, referred to the motion of the five lesser planets, can be called the motion of commutation, because it either exceeds the mean motion of Saturn, Jupiter and Mars or is exceeded by the mean motion of Venus and Mercury; and how their stations and retrogradations are explained by that motion of the earth.

V. In the end, there adhered to Copernicus, and made the Earth turn with a threefold or at least a twofold motion, his own pupil Georg Joachim Rheticus, who expounded those motions in the very long *Narratio* usually appended to Copernicus's works, and commended them highly [Margin: Asserting the annual motion of the earth: Rheticus. Mästlin. Kepler. Galileo. Boulliau. Jac. Lansbergen. Hérigone. Gemma. Naiboda. Reinhold. Calcagnini. Zúñiga. Foscarini. Baranzano. Politianus. Bruno. Descartes. Philips Lansbergen. Schickard. Hevelius.]; Michael Mästlin, and Mästlin's pupil Johannes Kepler; Galileo; Boulliau, Jacob van Lansbergen and Hérigone, in the places cited in chapter 1, number 4; and besides these Gemma Phrysius [Gemma Frisius] in his letter to Io. Stadius [Johannes Stadius]; Valentinus Naiboda in Book 1 of the *Institutiones astronomicae*, chapter 16; Erasmus Reinhold in the *Prutenic Tables* and in his exposition of the Copernican hypothesis; Caelius Calcagninus [Celio Calcagnini]; Didacus Stunica [Diego de Zúñiga] in his commentary on Job; Paulus Antonius Foscarinus, the Carmelite, in his letter on the mobility of the earth and the stability of the Sun to Sebastianus Fantonus [Sebastiano Fantoni], General of the Carmelites; Redento Baranzano in part 2 of the *Uranoscopia*, page 42, and, in that work, Antonius Laurentius Politianus; and also Giordano Bruno in Book 3 of *De maximo et immenso*, the last chapter; Descartes in the *Principles of Philosophy*, part 3, from number 26 to 34; Philips van Lansbergen in his *Uranometria*, Book 3, and in the controversies on the annual motion of the earth; Schikardus [Wilhelm Schickard] and Johannes Hevelius in Books 5 and 7 of the *Selenographia*. Among these, however, Lansbergen and Boulliau do not admit that third motion of the earth by which the proper motion apparent in the fixed stars is accounted for by Copernicus; for they say that the fixed stars in reality move slowly eastward. Nor, on the other hand, does Giordano Bruno accept any other motion of the earth besides the diurnal and the annual: in place of the third he substitutes a motion of the Sun in a circle bounded by the Tropics, from which the annual inequality, and the variation of the eccentricity and of the magnitude, are to arise. Rothmann, however, who had once clung tenaciously to Copernicus, afterwards surrendered to Tycho [Margin: Rothmann's palinode against Copernicus.] — if we believe Tycho himself, in the *Epistolae Astronomicae*, page 192; we shall report his words below, in chapter 29, number 19, and chapter 30, number 7.

SCHOLIA.

Scholia.

Vbi de alijs quibuſdam Motibus Terræ affictis.

Where certain other motions ascribed to the Earth are discussed.

I. Among the motions attributed to the Earth, the most celebrated are the three already mentioned, according to the view of Copernicus; and besides these there is the motion of trepidation [Margin: The motion of trepidation.]

— on which Petrus Alliacensis, treating it as a problem, in question 3 on the *Sphere*, and others, cited and rejected by us in Book 2, chapter 3, number 1 — a motion that Athanasius Kircher nevertheless favours in Book 2 of the *Magnes*, page 489. Andreas Cisalpinus [Andrea Cesalpino], moreover, in Book 3 of the *Peripateticae quaestiones*, question 4, imagined in the Earth a certain very slow motion toward the east, such as others recognize in the fixed stars as their proper motion; of this there is no need to say more.

II. Ioannes Pena, too, introduced a certain new rectilinear motion of the Earth, upward and downward, in the preface on the use of optics addressed to Cardinal Charles of Lorraine and prefixed to Euclid's *Optics*, which he himself translated from the Greek into Latin; and so did Io. Stadius, in the history of astronomy placed before the *Tabulae Bergenses*, page 23 [Margin: A motion of the Earth upward and downward, asserted by Io. Pena and Stadius.]. With these authors the basis of this motion is the apparent inequality in the motion of the fixed stars, which he attributes to optical causes, and to the Earth's approach to the fixed stars and its recession from them. But it will be best to draw this opinion out of his own words. He says, then: *It is a rule of optics, as true as it is brief, that of bodies carried with equal speed, those which seem to be carried more slowly are farther away. Now the fixed stars are carried with equal speed (for the hypotheses of astronomy teach that the celestial motions are uniform, although they appear non-uniform to us); yet they seem to advance unequally, as the observation of the ages teaches. For at the beginning of the periods of Callippus, that is, in the times of Alexander the Great, the fixed stars travelled one degree of the heaven in seventy-two years; in the age of Ptolemy, in a hundred years; in the time of Machometus Aracensis [al-Battānī], in sixty-six years; and in this century they advance at almost the same rate as in those first times of Callippus* [Margin: The first basis of Io. Pena.]. *From this*[35] *it is evident that the globe of the Earth was farthest from the heaven in the century of Ptolemy, came closest to the heaven in the times of Machometus, and in our age stands midway between the two extremes. So you see, most illustrious Prince, that it is concluded from optics that the Earth must be now nearer to the heaven, now farther from it: that is, that it has some motion by which it changes place. I do not wrap the earth in a threefold motion; I do not assign to it the diurnal and the annual motion, the motion both of the centre and of declination; I only assert, from optics, that the Earth advances by some motion from place to place — and that with a very slow progression of time, since scarcely in four hundred years or more can any such inequality of the motions be perceived. By this the other question, too, about the middle of the world is resolved: for if the earth changes place, how will it be the centre of the world? Thus the old controversy of the wisest men will be illuminated by the light of optics, and settled with very little trouble.*

III. So far Pena. In the same preface, a little earlier, he had built up the same motion of the earth from the unequal apparent magnitude of one and the same fixed star [Margin: The second basis of Io. Pena.], supposing that the

[35]printed *qno*, a turned u

diameters of the fixed stars are now seen larger than in Ptolemy's time, because of the earth's approach to them. But with the same ease of invention — not to say futility — he could have asserted that the eighth sphere itself moves to and fro, up and down along its diameter, approaching the immobile Earth and in turn receding from it. That this inequality of the motion of the fixed stars is improbable, however, or at least that their uniformity, even apparent, is more probable, we have shown sufficiently in Book 6, chapter 17. And how falsely it is supposed that the diameters of the fixed stars now appear larger than in Ptolemy's age is clear from what was said in Book 6, chapter 9, and Book 7, section 6, chapters 9 to 13. This writer ought also to have noticed how much greater and more frequent an inequality would appear in the motion and magnitude of the planets, especially of the Moon, if that approach and recession of the Earth were admitted; indeed, that it would become necessary either for the Earth to rise above the heaven of the Moon and the Sun, or at least for the centre of the planetary system, and with it the heavens of the planets, to rise together with the centre of the earth from the centre of the world toward its outer limit by as much as about a tenth part of the distance of the fixed stars. This will be demonstrated by the following diagram.

IV. Let AB be an arc of one degree of the heaven of the fixed stars, described from the centre of the world C [Margin: How far the Earth would have to rise, if the inequality of the motion of the fixed stars arose from its motion.]; and in that centre let the centre of the earth likewise stand in the age in which the fixed stars are supposed to complete one degree by their mean motion in 72 years. Let AC, or BC, the distance of the fixed stars according to Ptolemy or al-Battānī, be taken as 19,000 semidiameters of the earth. Then let the earth be carried to D in the age in which the fixed stars are supposed to complete one degree in 66 years; for then, by the rule of proportion, they will be seen to complete in 72 years 1° and 5′ 26″ besides. Therefore the arc AB, seen from C under the angle ACB, will appear as 60′; but seen from D under the angle ADB, it will appear as 65′ 26″. Therefore, by proposition 32 of the first book of the *Elements*, the angle CDB in triangle BCD will be 178° 54′ 34″, and the angle CBD will be 5′ 26″. Since, then, all the angles in that triangle are given, and besides them the side BC, of 19,000 semidiameters of the earth, the side DC too will become known with the help of trigonometry; and by the second case of oblique-angled triangles DC will be found to be 1900 terrestrial semidiameters and more. This measure exceeds Ptolemy's distance of the Sun from the centre of the world, let alone that of the Moon. Therefore the Earth's centre would have had to rise, between the time of Callippus and the age of al-Battānī, from the centre of the world to above the Sun; or at least the whole system of the planets, together with the earth, would have had to rise from the centre of the world by 1900 semidiameters of the earth and more [Margin: Either an error of Io. Pena in geometry, or audacity.]. Let Pena see, therefore, either how greatly he erred in geometry and in optics itself, or how much further he would have

had to venture, and what hypothesis he would have to swallow, if he wished to defend his opinion.

Diagram. A small woodcut set in the right column beside the demonstration of § IV: a tall, narrow figure. A slightly curved line at the top joins A and B, the arc of one degree of the heaven of the fixed stars; a vertical line descends from A to C, the centre of the world, at the bottom; D, the displaced centre of the earth, stands on that vertical about two-thirds of the way down from A; straight lines run from B to D and from B to C, so that the angles ACB and ADB stand at C and D under the same arc AB.

- A (upper left): end of the arc AB
- B (upper right): end of the arc AB
- D (on the vertical, lower part): the earth's centre carried to D
- C (bottom): the centre of the world

V. But I also find another slip of Pena's, in the history of astronomy [Margin: A slip of the same author in the history of astronomy.], when in the same preface to Euclid's *Optics* he says: *Let Aristotle have judged that the Earth is at rest; let Ptolemy, most experienced in celestial matters, judge so; let Theon judge so; let common credulity have judged the same. But those noble Pythagoreans judged otherwise, and pronounced that the earth moves. The same is asserted by Plato's Timaeus, by Philolaus, Ecphantus and Seleucus* [Margin: Seleucus asserts the motion of the Earth.]; *the same is taught by Aristarchus of Samos, by Archimedes and, in this age, by the most illustrious Copernicus.* But granted that Timaeus judged that the earth moves — which is, however, by no means certain, as is clear from what was said in this chapter 3, number 3 — it is clear from the same chapter, number 2, that Archimedes cannot be counted among those who move the Earth, since he rejected Aristarchus's opinion, even though, granting Aristarchus's hypothesis and the immense distance of the fixed stars, he showed in the *Arenarius* that the number of grains of sand contained in the whole capacity of the world can be computed.

VI. On the motion of the Earth in the meridian, by force of which the northern altitudes of the Pole increase continually [Margin: A motion of the Earth changing the altitudes of the pole.] — a motion devised by Dominicus Maria [Domenico Maria Novara] and followed by Giordano Bruno, page 306, and by Maginus in canon 8 of the *Secundorum mobilium* — we shall say more in chapter 11, from number 7; and there, at number 9, on the motion of libration from Africus to Caecias asserted by Alexander Calignonus.

CAPVT IV.

Chapter IV.

Explicantur diſtinctè tres quatuorue Motus Telluri à Copernico, & ſectatoribus attributi, eorumq. proprietates, & conditiones admirabiles.

The three or four motions attributed to the Earth by Copernicus and his followers are explained distinctly, together with their remarkable properties and conditions.

I. Whoever wishes either to defend or to attack the Copernican hypothesis must certainly first have explored it most thoroughly and looked deep into all its parts, so as not to expose himself — as has happened to not a few until now — to the ridicule and contempt of the Copernicans. Above all this holds for the man who thought that the diurnal revolution of the earth takes place from east to west, whom Galileo rightly mocks in the second Dialogue. It must therefore be known that three motions are attributed to the Earth by this sect. The first is called the Diurnal, or the motion of diurnal revolution, because in the time of 24 hours, in which one natural day is completed, the whole earth revolves about the centre of its body from one point to very nearly the same point. The second is called the Annual, because its revolution is not completed except in one solar year. The third is called the motion of declination, or of parallelism. We shall now explain these distinctly.

Explicatur Diurna Terræ reuolutio.

The diurnal revolution of the Earth is explained.

II. First, Copernicus, in Book 1 of the *Revolutions*, chapters 5 and 8, denies that the fixed stars and the planets move from east to west with any motion of the primum mobile, as astronomers commonly suppose. In place of this motion he substitutes a diurnal rotation of the terrestrial globe — a globe composed of earth, the water enclosed in it, and the air poured round it and akin to it — by which it revolves about the centre and axis of its body in 24 solar hours, from the west through the meridian toward the east [Margin: The direction in which the diurnal motion of the Earth tends.]. For all things that seem to move with respect to place seem to move so either because they really change place; or because, while they are unmoved, the sight or eye of the observer moves; or because both the object seen and the eye of the observer move unequally. For if the sight and the object moved with equal speed toward the same part of the world, no motion would be perceived between the thing seen and the observer's eye, as Copernicus argues admirably in that chapter 5. Whether, therefore, the diurnal revolution toward the west is assigned to the stars, or that revolution is attributed — but toward the opposite side, namely toward the east — to the Earth and to our sight, which views the stars from the earth, all the phenomena of the diurnal motion will appear to us in just the same way. As we go to meet them, the stars will seem to rise and gradually ascend above the Horizon as far as the Meridian; and as we for our part pass on beyond them and leave them behind our backs, they will seem to descend to the Horizon

and at last to set. Nor will the stars themselves pass through the vertex or the Meridian by a diurnal motion of their own; rather, the vertical points of the Earth themselves, and the meridian circles themselves, conceived on the globe of the Earth, will pass from the western quarter to the eastern; and so the Sun, now covered, now uncovered, will bring about the alternations of night and day. Since, then, from what has been said, the phenomena of the diurnal motion can arise in either way, it seemed more probable to Copernicus to ascribe that motion not to the whole world, nor to the huge spheres of the fixed stars and the planets, but rather to the Earth, inasmuch as it is spherical and small in comparison with the heaven, and is, as it were, the thing contained and placed. He indicates these reasons in these words of chapter 5 [Margin: The bases of Copernicus for the diurnal motion of the Earth.]: *But if you grant that the heaven itself has nothing of this motion, and that the Earth turns from west to east, you will find, if you consider it seriously, that this is how matters stand as regards the apparent rising and setting of the Sun, the Moon and the stars. And since the heaven is that which contains and conceals all things, the common place of all, it is not at once apparent why motion should not be attributed to the contained rather than to the container, to the placed rather than to the placing. Heraclides and Ecphantus the Pythagoreans, and Nicetas of Syracuse in Cicero, were indeed of this opinion, turning the earth round in the middle of the world. For they thought that the stars set through the interposition of the earth, and rose through its withdrawal.* Then in chapter 8, having established as certain that the Earth, enclosed by its poles, is bounded by a globular surface, he went on: *Why, then, do we still hesitate to grant it a mobility that by nature suits its form, rather than have the whole world slide round, whose limit is unknown and cannot be known; and why do we not confess that the appearance of the daily revolution is in the heaven, and its truth in the earth?* Finally, in Book 1, chapter 11, asserting a threefold motion of the earth, he calls this diurnal one the *First*, which he says the Greeks call νυχθημέρινον [Greek: nychthēmerinon, "of a night and a day"]: the circuit proper to day and night, turning about the axis of the earth from west to east, as the world is thought to be carried in the opposite direction, and describing the equinoctial circle.

III. That the stars, however, are commonly thought to move toward the west rather than the Earth toward the east, Copernicus ascribes to a popular error very like the one by which sailors sometimes think that their ship stands still and that the shores and banks flee in the opposite direction [Margin: By the simile of sailors the opinion of those who think the Earth does not move is set out.]. For he says in that chapter 5: *This is just as if Virgil's Aeneas were saying:*

We are carried out of the harbour, and lands and cities recede.

For as a ship floats along in calm weather, everything outside is seen by the sailors to move according to the image of that motion, and they in turn think that they themselves are at rest, with everything that is with them. So, indeed, it can happen in the motion of the earth that the whole world is thought to go round. I showed in chapter 2, number 3, that this simile was used before Copernicus by Nicolaus Cusanus

[Margin: The same simile used by Cusanus and Buchanan.]. Indeed, not a few years before Copernicus's *Revolutions* were published, Georgius Bucanhanus [George Buchanan], a Scot, in Book 1 of his *Sphere*, written in most elegant verse, acknowledged the same simile, speaking in the person of the ancient Pythagoreans, but rejected it when he sang:

Since there is nowhere any violence of a mass so great That it could heave from its seat, and move by force, The heap of the Earth. Nor again does it turn itself Round in a circle, as a great part of the ancient sages falsely Believed, sworn to the words of the Samian master: For it is the eyes that watch the fires of the stars that are deceived, Which think the heaven is whirled round in a swift vortex While the earth stands unmoved; as when a ship flees the shore And skims the salt shallows with a following wind, And the hills flee, and the woods and cities recede, So night dulls the bodily senses with its darkness.

Kepler too, in Book 1 of the *Epitome of Copernican Astronomy*, page 130, heaps up other similes besides this one [Margin: Kepler's similes.]; for he adds: *Whoever sails downstream, unless he has been warned beforehand, will think that the nearby banks are moving the opposite way; and if the ship is carried past a stake that stands submerged with the current washing over it, the passengers will cry out that an otter is coming up to meet them. Whoever rides forward in a carriage between hedges will swear that the hedges on both sides are running at him; whoever rides backward will swear that the hedges are fleeing — an impression that the eyes conceive and retain, deeply imprinted, even when the man comes to a pause. And whoever is carried backward in a carriage away from some tower of remarkable height, along a road leading straight from the tower, will dread the fall of the tower bearing down on his head. So too, having watched a cloud breaking open* [?] *and widely spread, moving gently from south to north, a man will swear that the stars which fall into its rifts and shine out from them are moving with the contrary motion, from north to south.* Pierre Gassendi, for his part, in Letter 2, *De motu impresso a motore translato*, uses the example of two ships [Margin: Another simile of Gassendi's for this matter.]. Whether another ship moves toward ours while ours is unmoved, or ours moves toward another unmoved ship, he says that the motion nevertheless always appears to be not that of our ship but that of the other. So much so that, if we are in mid-sea, with nothing but sky on every side and sea on every side, we seem to ourselves to stand quite unmoved, however much we are driven by a following wind and carried toward another ship held fast by its anchors; and that ship will therefore appear to approach us exactly as much as we in reality approach it. This would happen above all to a man either born and brought up on a ship, or carried onto one while asleep and waking afterwards, and having no other means of correcting the illusion of his eyes. Having set these things out first, he adds: *Now the globe of the Earth is that onto which we have been carried as if asleep, or rather on which, not aware of it, we were born. And from the time we opened our eyes and, besides this globe, contemplated another, namely the Sun, in the same expanse, as it were, as the Earth, or in the space of the world, the question has been which of these globes rest would belong to, and which motion. And*

we, without hesitation, pronounced that rest undoubtedly belongs to the Earth and motion to the Sun. Pythagoras, Plato, Aristarchus and other ancients, and likewise Copernicus, Galileo, Kepler and many more recent writers, have warned that perhaps we are deceived, and that the Sun is at rest and the Earth moves. But he draws Pythagoras and Plato into this opinion too absolutely, as is clear from what was said in chapter 2.

IV. [Margin: Why this motion is commonly attributed to the stars rather than to the Earth.] Someone may ask why that motion, which could equally have been attributed to either while saving the phenomena, has usually been assigned to the stars rather than to the Earth. Kepler replies, in the *Epitome of Copernican Astronomy*, page 130, that motion is not the proper object of sight but is judged by the common sense, and that the common sense is deceived in this for two reasons. First, a man supposes that his eyes are at rest whenever he knows that the motion by which his eyes are carried does not come from his own internal motive faculty, or when he does not recognise that motion by any evidence of jolting; and therefore he judges that the object, rather than his own eyes, is moving. Second, we are inclined to attribute rest to things that are much larger than the eye and are widely spread out, as being hard to move — especially if they keep the same position relative to the eye — and to ascribe motion to smaller things. Now the fields and seas of the Earth appear much larger than the stars taken singly; so from childhood we have grown used to attributing motion to the stars rather than to the Earth. Galileo, moreover, in Dialogue 2 on the World System, affirms that we must necessarily fail to perceive this motion by sense, and that it is imperceptible to us, because we inhabit the Earth and share equally in the same motion. But let these things be said in passing [Greek: παρεργῶς (parergōs, "in passing")]; we must return [?] to unfold the other conditions of this diurnal motion.

V. [Margin: The kind of the Earth's diurnal motion.] The motion of the Earth, then, which we have so far said tends eastward according to Copernicus, is a kind of whirling or spinning [vertigo … seu turbinatio], by which the Equator of the terrestrial globe itself, together with all the terrestrial parallels, is turned round the axis of that same Equator in the space of 24 hours. This Equator lies in the plane of that imaginary Equator which writers on the sphere commonly employ to explain the motion of the primum mobile. The axis of the Earth, if it were produced beyond the Earth, and if the Earth were moved by no other motion than this diurnal one, would meet the poles of the World at either end. What happens to the axis so produced when the annual motion of translation, and the motion of the axis itself, are mixed with the diurnal motion of whirling, I shall say more fittingly below. Meanwhile we may know that on the globe of the Earth there are two poles, or immobile points, which stand at rest, to sense, beneath two opposite points of the heaven; that the parts of the terrestrial surface nearer those points describe small parallels and therefore move more slowly, while those farther from them describe larger parallels and turn more swiftly; and that the greatest circle, the terrestrial Equator, turns

most swiftly of all. In Copernicus's view, moreover, there is a single Equator, and it is terrestrial, and its motion alone suffices to explain everything that others explain by the celestial Equator and its parallels, as is plain from Book 1 of the *Revolutions*, chapter 11, and Book 3, chapter 1. Finally, that this motion is uniform and circular is to be established above all by this sign, as Kepler notes in the *Epitome of Astronomy*, page 111: those who, following Tycho's example, use armillae — that is, perfect circles — to measure differences of right ascension and the motion of the primum mobile set them so that their axis is perpendicular to their planes and elevated by as much as the elevation of the Pole of the World; and sighting on the stars through the sights fixed to the rim of the armillae, they see the stars go round the rim of the armillae uniformly. Besides[36] this, the spherical figure of the Earth itself demands that this whirling be circular rather than of any other shape.

VI. [Margin: The diurnal motion common to the Earth, the Water and the lowest air.] Nor, in Copernicus's view, is it only the element of Earth that is turned eastward by the diurnal motion. So too is all the water enclosed in the Earth's hollows, and that part of the air which is contained within and around all the highest mountains, or rises a little above them, inasmuch as it is akin to the Earth and the Water and consists of the vapours and exhalations of both — even though, because of its thinness, it may seem to us to be elemental air. Hence it happens that, because of this common whirling, neither those sailing westward, nor birds or clouds travelling toward the same quarter, experience any resistance from the water or from this air, as if it were striving against them. Indeed all terrestrial and aquatic bodies, and so all birds as well, and finally all mixed bodies, so long as they have not left this lower region of the air, share in this common motion, which they therefore do not feel, because it is common. But whether this motion of the water or of the lower air comes from some nature common to it and to the Earth, or rather from a seizure [raptus] made by the Earth, Copernicus did not determine. For in Book 1, chapter 8, he says: [Margin: By what force the water and the air are moved by this motion?] *What then shall we say of the clouds and the other things that hang in the air in any way, or sink, and again tend upward? Only that not the Earth alone, with the watery element joined to it, moves in this way, but also no small part of the air, and whatever things have a kinship with the Earth in the same way. Either because the nearby air, mixed with earthy or watery matter, follows the same nature as the Earth; or because the motion of the air is acquired, and it shares it from the Earth through contiguity, by perpetual revolution and without resistance.* Of the upper portion of the air, in which he thinks comets are formed, he adds these words: [Margin: The upper region of the air is exempt from the diurnal motion.] *We can say that this part of the air, because of its great distance from the Earth, is free of that terrestrial motion. Hence the air that is nearest the Earth will appear tranquil, and so will the things*

[36]printed *Ptæterquam-*, for *Præterquam-*

suspended in it, unless they are driven to and fro by the wind, or by some other force, as happens.

So you see that in this hypothesis everything is reversed. Those who assign the diurnal motion to the heavens think that the element of fire and the upper region of the air are carried westward with it, the lowest region remaining unmoved; whereas those who with Copernicus impose this whirling on the Earth think that the lowest region of the air is carried eastward with the Earth, the highest being immobile. But a further distinction must still be drawn within the lowest air: whether some part of pure air, distinct from the vapours and exhalations, is intermixed with them. For this pure air is carried by force by the very whirling of the terraqueous globe, and by the very vapours and exhalations that surround it; while the vapours and exhalations themselves are moved by nature itself, and by the same faculty by which the Earth itself and the water are moved — a faculty of which we shall have to speak below. [Margin: A perpetual breeze within the Torrid zone toward the West.] But if some part of the air around the Earth, because of its distance from the poles, is less subject to vapours and exhalations — such as the part that lies within the Tropics and is spread widely over the most open and vast expanses of the Ocean — that part, as Galileo held in Dialogue 4 on the World System, page 327, and Pierre Gassendi in Letter 2, *De motu impresso a motore translato*, as we shall say in Scholium 5, complies less readily with the seizure of the terrestrial rotation. Therefore in that tract, while the Earth rolls eastward and the air is moved more sluggishly in that direction, a perpetual breeze is felt, passing through from the East with so constant a course that by its help too, not only by that of the running waters, ships are carried happily to the West Indies; and ships setting out from the same Indies, from the Mexican shores, carried forward by the same favour, plough the Pacific Sea toward the Molucca and Philippine Islands. Voyages in the opposite direction, eastward, are by contrast more difficult and of slower course.

VII. [Margin: What gravity and levity are in this hypothesis.] Heavy bodies thrown upward, or let fall through the air from a tower or from a ship's mast, are seen to fall perpendicularly onto the same place of the Earth, so that the Earth does not withdraw itself from under them; and all heavy bodies universally tend by their own nature toward the centre not only of the Earth but of the world, while light bodies rise from that centre. So that this should not stand in the way of the terrestrial motion, Copernicus lays down in Book 1, chapter 9, that gravity is not a principle of tending toward the middle and centre of the Universe, but an innate propensity to tend toward its own whole, so that the parts may be preserved together with it and may arrange themselves in a spherical figure about the centre of their whole. For he says: *I for my part think that gravity is nothing other than a certain natural appetency, implanted in the parts by the divine providence of the Maker of all things, so that they may gather into their unity and wholeness, coming together in the form of a globe. And it is credible that this affection is present also in the Sun and the Moon and the other wandering lights,*

so that by its efficacy they remain in the roundness in which they present themselves; and yet they make their circuits in many ways. Therefore, if any part of the Moon or of the Sun could be torn away from their globe, once left to itself it would fly back not to the centre of the universe but to the globe of the Sun or of the Moon. For it is not the centre of the Universe, be- ing a point or nothing and lacking all appetibility, as Kepler notes in the *Epitome of Astronomy*, page 95, that is rightly set as the terminus toward which all heavy bodies tend; it is rather the Earth itself with its centre — not insofar as it is a centre, but insofar as it is the middle of that whole to which the kindred parts are borne. Kepler adds there, however, that this tendency of the parts toward their whole does not occur without a certain magnetic attraction; this, however, is excellently refuted by Cabeo in Book 1 of the *Philosophia Magnetica*, chapter 19. And if you urge that light bodies are carried upward, Copernicus will reply, in Book 1, chapter 8, that there is no fire other than this earthly one, or burning smoke, whose property is to extend whatever it has invaded, and that extensive motion runs from the centre to the circumference; but that this earthly exhalation or smoke is snatched upward and thrust out of its own place, and therefore at once grows faint, as though confessing the cause of the violence done to the earthly matter; and that, for this reason, levity does not exist, or is not connatural to these bodies.

Therefore, from the motion of heavy bodies toward the centre of the Earth, or of light bodies away from it — a motion that would have to take place along the shortest line, and so a straight one — and from the motion of whirling which these same bodies share with the Earth toward the East, it follows that things projected or thrust upward, and things falling downward, ascend and descend by a certain motion mixed of straight and circular. Granted, this common motion, precisely because it is common to the eye of the onlookers, who are carried along with the Earth, is not perceived, and so the motion appears to be only rectilinear and made along the perpendicular. But that it is mixed of straight and circular Copernicus taught in Book 1, chapter 8, and that in it the circular prevails, because the circular is unfailing and uniform, is intended per se by the nature of these bodies, and is common to the whole world; whereas the straight does not belong to them unless they are badly placed and set outside their own place, and it is unequal, and it is not distinguished from the circular in reality but only in thought, as a point is distinguished from a line and a line from a surface. But we shall report these very things in Copernicus's own words in chapter 5, number 17. Here let these words suffice: *We must admit that the motion of falling and rising bodies is twofold in comparison with the world, and altogether compounded of straight and circular;* and below: *Since, then, circular motion belongs to wholes, while parts have straight motion as well, we can say that the circular remains with the straight, as the animal does with the sick. Indeed, Aristotle's division of simple motion into three kinds — from the middle, to the middle, and about the middle — will be thought to be only an act of reason. In the same way we distinguish line, point and surface, although one cannot subsist without another, and*

none of them without body. Therefore in this hypothesis the motion of heavy bodies and of light bodies, upward or downward, does not take place along a line that is truly straight, but along one mixed of straight and circular, which are nonetheless distinguished only by reason. What kind of line this is will be discussed more conveniently in the scholia of this chapter (so as not to break the thread of this account too much), and more fully in chapter 17, from number 6.

VIII. [Margin: Kepler's doctrine on the principle of the Earth's diurnal motion.] So far we have set out with Copernicus the nature and conditions of the diurnal revolution of the whole globe, composed of earth and water and the atmosphere poured round it, and of terrestrial and aquatic bodies as well, inserting a few things from Kepler and Gassendi. Now certain other things must be added which Kepler devised, either of his own or from Gilbert's work on the magnet. In the *Epitome of Copernican Astronomy*, Book 1, from page 116 to 128, investigating the efficient and the subjective cause, together with the dispositions toward this diurnal motion, he holds that the terrestrial globe, and the whole Earth insofar as it is a whole, has no natural motion with respect to its matter, but rather an inertia toward motion and a certain resistance, especially in its denser parts and those nearer the centre. If, however, one considers its form, which is a certain faculty and soul moving it round in a circle, this whirling is natural to it, since nothing is more natural to matter than its form, or to a body than its soul. Thus the nature of the magnet tends downward because of its gravity, but by the species of its form ascends to another magnet, and that ascent is not violent but natural. Thus too the courses of animals poising themselves in the air, and the leaps and pounces of cats and of serpents, are not violent for the whole animal, if you consider the soul that demands such motions, although with respect to bodily gravity they may seem violent in a certain respect [secundum quid]. But before this soul moved the Earth, [Margin: God the first author of this whirling.] he says on page 120, God in the beginning impressed this diurnal whirling on the Earth, and from it all the subsequent rotations have flowed on by continued vigour, just as boys spinning a top impress on it an impetus for a great many gyrations; and to this day more than two million [vicies centena millia] diurnal whirlings have been completed. This vigour persists still because no external roughness or density of the ethereal air opposes it. Nor can any cause be given why the Earth revolves toward this quarter, namely toward the East, rather than toward another, except this: that it was set rotating toward this quarter by the Creator at once, in the beginning. Since, however, the vigour of this motion could be weakened by the inertia of the resisting Earth, or by the ebbing of an impetus gradually growing faint, two things contributed to the perpetuity and uniformity of this whirling: the impression of the motion, made according to the disposition of the Earth's parts, and a faculty and soul, motive and conservative of the original impetus, implanted by God.

IX. [Margin: Magnetic fibres of two kinds in the Earth's globe. [?]] As regards the disposition of the parts, Kepler, on pages 116 and 121, recognises

in the Earth's globe fibres or filaments of two kinds, just as in a great magnet. Those of the first kind are rectilinear fibres parallel to its axis; by virtue of them, if the globe is moved, it keeps itself in its original position, just as the Earth's axis, wherever it is carried, directs itself toward the same quarter of the world in which it was from the beginning, and always remains parallel to itself, and so has the character of something at rest, or retaining the same position. Moreover, because of such fibres parallel to the axis, the terrestrial globe has a faculty of directing magnets, and all magnetic things, toward itself; and magnets in turn have a faculty of turning themselves toward this quarter of the Earth and of conforming to its axis, or directing themselves toward the poles of the Earth — as do magnetic tongues or needles too, unless they are forced to decline toward great continents or nearby mines of magnets, where the motion is mixed in proportion to the moving principles. The fibres of the second kind are circular, like circular threads, into which those rectilinear fibres parallel to the axis are woven, standing circularly round the axis. This could be illustrated in some measure by the example of certain spiders, which weave their filaments with rectilinear rays and circular tracts. But Kepler, on page 122, preferred to use the example of fibres not merely twofold, as in the terrestrial globe, but threefold, found by anatomists in the substance of the stomach; the anatomists likewise recognise, among those three mutually interwoven orders of fibres, three faculties of the stomach: the attractive, along the straight fibres, upward; the retentive, along the transverse ones; and the expulsive, along the oblique ones, downward. But we have a more fitting example in trees. If their trunk is cut by a plane orthogonal to the pith, or axis, veins appear arranged in a circle in such a way that the ducts of the pores both tend upward — which is why the wood comes out fissile — and diverge transversely, like rays, from the pith toward the bark. Therefore it is by virtue of these circular fibres that a motion impressed along them is one of circular whirling about the axis, describing circles at right angles to the axis. Accordingly Kepler says on page 121 that it is likely that that very species of the first rotation, impressed by God on the Earth and continued, insinuated itself into the body of the Earth along the course of the rectilinear fibres, but arranged circularly about the axis, and was transformed as it were into a special bodily form that conserves this diurnal motion — no longer as a guest, as the impetus is in a top spun by boys, but as an inhabitant, and now the conqueror and tamer of matter, which of itself is inert; or at any rate that this impetus, with the rectilinear fibres demanding rest in the same position and the circular fibres demanding circular motion if any is impressed, is the proximate disposition required by the soul and the motive faculty. For he concludes on page 122 that even if this bodily form of the fibres were alone the cause of motion, what is moved and what moves would still not be the same; and that the same globe, by reason of the rectilinear fibres, rests in the same position and underlies the motion, while by reason of the circular fibres it continues the impetus it has received into circular motion.

X. For many reasons, however, besides the impetus once impressed on the Earth by God, and besides its species, conformed according to the position and disposition of the fibres already mentioned, a certain soul and a faculty, not intelle- ctive, not sensitive, not vegetative, but purely motive, and forming certain figures, must be added to the Earth, as Kepler held from page 123 on. [Margin: Foundations to be laid for a motive soul in the Earth's globe.] For just as bones, nerves and muscles are instruments and dispositions for motion rather than its moving cause, so too are the magnetic fibres of the Earth and the impression made along them. Next, the vigour, speed and uniformity of this motion will be more securely preserved if it comes from a soul, as from an internal principle and source, which reproduces its acts for itself like an Entelechy and restores itself, than if it comes from an extraneous principle, or from an impetus sojourning as a stranger in a foreign subject; and it will be the more like the first mover, God, who is the supreme Intelligence, if it is a soul than if it is not. And that very direction of the axis, brought into second act with so great a uniformity of circular motion, and one so perennial, is an argument for a soul which, if not intellective, at least governs this motion by some instinct. To these are added other indications of this soul: namely the perpetual and sensible subterranean heat — for just as cold is proper to matter, so heat is a trace of soul — and likewise the faculty that forms fossils, minerals, and the hexagonal stones in certain crystals and salts, similar to the faculty that forms hexagonal snow in the air, flies and locusts, and so many monsters in the water. And in the introduction to the *Commentaries on Mars* he says that if the Moon and the Earth were not each held back in its own circuit by an animal force, or by some other equivalent force, the Earth would ascend to the Moon by a fifty-fourth part of the interval, and the Moon would descend to the Earth by the remaining fifty-three or so parts of the interval, and there they would be joined by mutual magnetic attraction — provided, however, that they were of the same density.

XI. [Margin: The Earth a great magnet, according to Gilbert.] What Kepler devised concerning the soul of the Earth and the course of the magnetic fibres had, however, been anticipated by William Gilbert. For in Book 5 of *De Magnete*, chapter 12, he had asserted that the magnetic force, because of motions so varied and wonderful, is either animate or an imitator of soul; and by experiments with the terrella he had tried to show, especially in Book 6, chapter 4, that the globe of the Earth is a great magnet. The terrella is nothing other than a magnet turned into the form of a globe or sphere. In it the experimenter will be able to detect two poles and faces terminating its axis; and magnetic needles placed on it always conform to its axis in their length, but in altitude are inclined more or less toward the poles of the terrella, according as they are more or less distant from them. Since, then, similar things happen to magnetic needles with respect to the axis of the Earth, he thought he could gather from this, with fair probability, that the Earth is a great magnet. And just as the globe of a terrella, enclosed in a wooden box so that it can float, and set on

water so that its north pole points to the South, turns itself by a circular motion about its centre until its north pole faces the North, so he judges that the Earth is fitted for a magnetic revolution, so as to preserve the position it once had toward the poles of the World. This would be truer still if, as Petrus Peregrinus [Pierre de Maricourt] affirms, the globe of a terrella, suspended on its poles in the meridian, revolved in 24 hours. But our Cabeo, in Book 1 of the *Philosophia Magnetica*, chapter 19, taught by excellent arguments that the Earth is not a great magnet; nor, as we shall show below in chapter 7, numbers 10 and 11, is the Earth's diurnal turning rightly deduced from the turning of a terrella toward the poles. Further, Gilbert, in Book 6, chapter 5, himself also held that gravity is an appetency of the terrestrial parts to tend toward their primary globe; and he placed this appetency also in the parts of the celestial globes, with respect to their primary globes, namely the Sun, the Moon, and so on.

XII. [Margin: A fourth cause of the Earth's diurnal motion according to Kepler, namely the Sun.] Besides the causes already mentioned by which the diurnal revolution of the Earth comes about, Kepler recognises yet a fourth, in Book 4 of the *Epitome of Copernican Astronomy*, from page 550: namely the Sun. He does so in order to give a physical account of the equation of natural days, which he had set out in Books 1 and 3, that is, on pages 108 and 286, and which we treated in Book 3, chapter 32, number 4 — the equation, that is, which, as Tycho found by experience in eclipses, supposes the Earth's summer revolution to be a little slower than its winter one. This, he says, arises from the interval between the Sun and the Earth being greater in summer than in winter, because of which the Earth's faculty is then less strengthened by the Sun than in winter. This inequality of the diurnal revolution is also recognised by Longomontanus in Book 1 of the *Theorics*, the chapter on the Sun, and by Boulliau in Book 2 of the *Astronomia Philolaica*, chapter 6. Kepler therefore assumes that the archetypal number of the Earth's revolutions within one year ought to have been round, namely of 360 days, rather than composed of unarticulated, ignoble and broken numbers, namely of 365¼ days; and that the Earth, accordingly, if it were not stimulated by the Sun, would be moved more slowly in its diurnal revolution, since it would then revolve 360 times within the year. Therefore the fact that it adds five supernumerary revolutions and a quarter of a day is to be attributed to the speed of the Earth, stimulated by the Sun's light the more strongly the nearer it is to the Sun. How that supernumerary portion is to be distributed into the parts of the physical equation of natural days, we have already taught from Kepler himself in Book 3, chapter 32, number 4. [Margin: The diurnal revolution of the Earth is the cause of the Moon's proper motion, according to Kepler.] Moreover, just as the Earth is stimulated by the Sun in its diurnal revolution, and just as all the primary planets, by their whirling about their own centre, emit a certain species by which, as though with a hand, they grasp their secondary planets — the Sun its six lesser planets, and Jupiter its satellites — and drive them round in a circuit, so the Earth, by gyrating about its axis, emits from itself a certain species by which it seizes the Moon and whirls

it round toward the same eastern quarter, as far as the Moon's inertia toward motion allows it to be carried round. And so, just as he attributes the motion of the other planets and of the Earth — but the annual motion, eastward — to the magnetic drawing-round by the Sun, through the species emanating from it while it turns about its centre, so he attributes the Moon's proper motion eastward to the diurnal revolution of the magnetic Earth, drawing the Moon round in a circle; and from this, he says, it comes about that the Moon is the swifter the nearer it is to the Earth. He confirms this from the kinship between the Moon and the Earth: through the telescope the Moon is seen to be another earth, roughened with mountains, seas and valleys, and the Moon produces the reciprocal tide of the sea by its passage over the vertices. But let it be enough, and more than enough, for our present purpose to have sampled these things from Kepler, in order to explain, illustrate and confirm Copernicus's hypothesis of the Earth's diurnal revolution.

Explicatur Secundus Telluris Motus, qui eſt Tranſlatio Annua Centri terreſtris per Orbem Magnum circa centrum Vniuerſi.

The second motion of the Earth is explained, which is the annual translation of the Earth's centre along the Great Orb about the centre of the Universe.

XIII. The second motion, which Copernicus, with Philolaus and Aristarchus, attributes to the Earth, is called the annual translation. By it the centre of the terrestrial globe is carried uniformly in the plane of the Ecliptic round the Sun, which is placed at or near the centre of the World, in the order of the signs, or toward the East; and it completes its mean period in 365 days and 6 hours. With the centre of the terrestrial globe, moreover, not only the whole Earth but also the whole elementary sphere, and the very body and system of the Moon, are carried round, since the Moon is the Earth's attendant and, as it were, its secondary planet. The Earth, then, becomes one of the six planets, and is not at the centre of the universe. The Sun, on the other hand, ceases in this hypothesis to be a planet, since it is not moved by the motion of translation, nor even by the diurnal motion of whirling, but remains immobile near the centre of the universe. The orb or circle which the centre of the Earth describes by this motion in the plane of the celestial Ecliptic is commonly called by Copernicus the Annual Orb [Orbis Annuus], but sometimes, as in Book 1, chapter 10, the Great Orb [Orbis Magnus], by comparison with the terrestrial Equator which the diurnal revolution of the Earth describes on the terrestrial surface, and which is indeed far smaller than this annual circle; for the annual circle, though distinct from the Sun's, is as large as the orb of the Sun is in the Ptolemaic hypothesis. It can also be called great because it has great equipollence and power, since it alone accomplishes what scarcely many other orbs can accomplish in the Ptolemaic system — although with respect to the highest sphere of the Fixed stars it is like a point. To this Great Orb, which we may also call the annual orb and the terrestrial Ecliptic, the terrestrial Equator is inclined at an angle of

23° 30′: as great, that is, as the obliquity of the celestial Ecliptic to the celestial Equator in the hypothesis of a standing Earth, and as great likewise as the inclination of the axis of the Ecliptic to the axis of the Equator, or the distance between the Poles of the Zodiac and of the Equinoctial circle. These things, which in summary concerning this motion we have touched on, must now be explained from what Copernicus and the Copernicans add to it.

XIV. [Margin: Copernicus's prelude to the annual motion of the Earth.] First, then, Copernicus, in Book 1, chapter 5, having mentioned the diurnal motion of the Earth, at once added: *If anyone should deny that the Earth occupies the middle or centre of the world, and yet not admit that its distance is so great as to be comparable to the sphere of the non-wandering stars, but hold it considerable and evident with respect to the orbs of the Sun and the other stars, and should think that their motion appears irregular for that reason, as though they were regulated about some other centre than the centre of the Earth, he could perhaps offer a not inept account of the irregular apparent motion. For the fact that the wandering stars are seen now nearer the Earth and now, the same ones, more remote necessarily argues that the centre of the Earth is not the centre of their circles. It is all the less settled whether it is the Earth that nods toward them and away from them, or they toward and away from the Earth. Nor would it be so very surprising if someone, besides that daily revolution, were to hold some other motion of the Earth: namely, that the Earth revolves, and wanders with several motions, and is one of the stars — as Philolaus the Pythagorean is said to have held, a mathematician of no common rank, for the sake of visiting whom Plato did not hesitate to go to Italy, as those who wrote the life of Plato report.*

With these words he paves the way for himself, by a kind of prelude, to the motion of the Earth along the Great Orb. And first he requires a distance of the Earth from the centre of the universe so great that it bears an evident proportion to the distances of the Planets from the same centre, but an unevident, or imperceptible, one to the distance of the Fixed stars. Next, from the fact that the diameters of the Planets appear now larger, now smaller, he infers that the Earth is not the centre of their motions; and that therefore that diversity, or second inequality — but the greater and more frequent one, which they call the anomaly of the orb, or the Argument, or which they attribute to the motion of the planetary orbs, referred to the Sun's approach or recession — can not ineptly be attributed to the motion of the Earth as it approaches them and recedes from them annually. And he fortifies himself with the authority of Philolaus. After this, in the same Book 1, chapter 9, having said that in the Sun and the Moon and the other Planets there is an affection and inclination of the parts toward their whole, so that they arrange themselves in a globe about their centre and are preserved together with the whole, and that this propensity is of the same kind as the one heavy bodies have toward the centre of the Earth; and that nevertheless the centre of those Planets is not the centre of the universe, but that they perform their own circuits — he added: *If, then, the Earth too should perform other circuits — for instance, about a centre — these*

must necessarily be those which likewise appear externally in many bodies, among which we find the annual circuit. For if it is changed from a solar into a terrestrial one, immobility being granted to the Sun, the risings and settings of the signs and of the Fixed stars (he is speaking of rising and setting with respect to the Sun's rays, that is, the heliacal) *by which they become morning and evening stars will appear in the same way; the stations, retrogradations and progressions of the wandering stars, too, will be seen to be not theirs but a motion of the Earth, which they borrow for their own appearances. Finally, the Sun itself will be thought to occupy the middle of the world.* See how he teaches that an annual motion can be granted to the Earth and immobility to the Sun — and in such a way that not only can all the appearances which used to be explained in the Sun and the other Planets by the annual motion of the Sun take place, but they can take place without the imperfection of a real retrogradation and station of the planets.

XV. Having touched on these things first, Copernicus, in the following chapter, that is chapter 10, treats of the order of the Planets in the system of the World. He argues both from their light, received from the Sun, and from the fact that the three superior planets become nearer the Earth about their evening rising, that is, when they are opposite the Sun, but are most remote when, having become morning stars, they are in conjunction with the Sun; and from the fact that Venus and Mercury, in the opinion of some of the ancients as well, go round the Sun. From this he concludes that not the Earth but the Sun is the centre of their motion, and that about it revolve Mercury, then Venus, after that the Earth with its attendant the Moon, then Mars, Jupiter and Saturn. And the annual motion of the Earth, which he had indicated in chapters 5 and 9 and had called not inept for saving the Phenomena of the heavens, he now, his shame at last overcome, introduces outright into the system of the World, saying: [Margin: Copernicus now introduces the annual motion of the Earth outright.] *But since all these rest upon one middle, it is necessary that the space left between the convex orb of Venus and the concave orb of Mars also be marked out as an orb or sphere, concentric with them on both its surfaces, which receives the Earth with its attendant the Moon and whatever is contained beneath the lunar globe. For we can in no way separate the Moon from the Earth, since beyond dispute it is the nearest to it — especially as in that space (that is, between the convex of Venus and the concave of Mars) we find a place for it that is suitable enough and ample. We are therefore not ashamed to confess that this whole which the Moon encircles, together with the centre of the Earth (that is, all the spheres of the Elements and of the Moon), passes round the Sun along that Great Orb, among the other wandering stars, with an annual revolution; that about it (that is, near the Sun) is the centre of the world; and that, the Sun also remaining immobile, whatever appears of the motion of the Sun is rather verified in the mobility of the Earth.* There follows, then, the order of the spheres as laid down and described by Copernicus, as you see in the system attached.

Diagram. The Copernican order of the spheres, set in the right column. The Sun, a rayed disc, stands at the centre. Round it run concentric circles: the

two innermost (dotted) carry the orbits of Venus and Mercury; next comes the Earth's circle, on which a dark globe (the Earth) carries a small epicycle with the Moon's sign; outside it the circles of Mars, Jupiter and Saturn; and outermost a circle set all round with star sorts, for the sphere of the Fixed stars. The labels run round the circles:

- Outermost labelled orbit (Saturn's sign): "Revolution of 30 years"
- Next (Jupiter's sign): "Revolution of 12 years"
- Next (Mars's sign): "Revolution of 2 years"
- Round the Earth's circle: "Of the Earth … and Lunar … annual revolution … orb … Annual" — the word set sideways on the right of this circle is unread [?]
- Second dotted circle (Venus's sign): "Revolution of 9 months" [?]
- Innermost dotted circle (Mercury's sign): "Revolution of 80 days"

In it the Sun is to be placed not, indeed, at the very centre of the World, if you listen to Copernicus, but about or near the centre of the world, at as great a distance from that centre as, among the Ptolemaics, is the eccentricity of the Sun's orb with respect to the centre of the Earth. For according to the Ptolemaics the Planets, in their second inequality or anomaly, look to the mean motions of the Sun, that is, the equal ones; and these the annual motion of the Earth here supplies about the centre of the world. About that centre Mercury, nearest the Sun, is carried round with a revolution of about 80 days; then Venus, in a [?] — that is, a looser and more remote — orb, with a revolution of about 9 months. About it the globe of Earth [?] and water, with the whole elementary sphere and with the Moon and the lunar heaven, turns in a period of 365 days and a quarter of a day; and above this orb Mars, in about two years, Jupiter in twelve, and Saturn in a period of three years [?], all revolve toward the eastern quarter; while the outermost sphere of the Fixed stars, separated from the circuit of Saturn by an almost immeasurable interval, rests immobile.

XVI. With this annual motion of the Earth substituted for the annual revolution of the Sun, two kinds of τῶν φαινομένον [Greek: tōn phainomenon, so printed for φαινομένων, "of the phenomena"], that is, of appearances, are simply explained: the first in the Sun and the Moon, the second in the five lesser Planets. On the Phenomena concerning the Sun let us hear Copernicus discoursing thus in Book 1, chapter 11: [Margin: Effects of the annual motion of the Earth with respect to the Sun alone.] *The second is the annual motion of the centre of the Earth, which describes the circle of the Signs about the Sun, likewise from west to east, that is, running forward in the order of the signs, between Venus and Mars, as we have said, together with the things lying upon it — that is, with the elements and the lunar heaven, resting on the centre of the Earth. Hence it is that the Sun itself seems to traverse the Zodiac with a similar motion: as, for example, when the centre of the Earth passes through Capricorn, the Sun seems to pass through Cancer; from Aquarius, Leo; and so on, as we have said.*

For, for clarity's sake, in the diagram immediately following let the Sun be near the centre of the Universe, at S. From this centre describe the celestial

Ecliptic with its four cardinal points, which the appropriate letters indicate: namely A, the beginning of Aries; C, of Cancer; L, of Libra; and K, of Capricorn. Then in the plane of this Ecliptic, and from the same centre, describe the inner circle EFBD, which the centre of the Earth traces annually by its motion, from E through F and B to D, until it returns again to E. This will become plain if the centre of the Earth is at E, under the beginning of Aries: then an eye at G, looking from the surface of the Earth at the Sun S along the line EGSBL, will see the Sun itself appear under L, the beginning of Libra. When the centre of the Earth has advanced from E to F, under the beginning of Cancer, an inhabitant of the Earth will see the Sun S, along the line FSK, under the beginning of Capricorn. Then, as the Earth proceeds to B, that is, to the beginning of Libra, the Sun will seem to be under the beginning of Aries, at A; and when the Earth has been carried on to D, under the beginning of Capricorn, the Sun will appear to it under C, which is the beginning of Cancer. And everything is to be understood in the same way of the other Signs, by opposition.

Diagram. The annual orb and the apparent place of the Sun, set in the left column. A large circle (the celestial Ecliptic) is lettered at its four cardinal points — C at the top, L at the left, A at the right, K at the foot — with a sign sort beside each. Inside it a circle centred on the Sun S carries four small circles, the Earth at the four quadrants of its annual orb, centred at F (top), B (left), E (right) and D (bottom); each small circle is lettered P, G, I, H about its centre. Straight lines through the Sun join opposite stations to the Ecliptic.

- Top: sign of Cancer; C; small circle with P, G, I, F, H
- Left: L, with a sign sort below it [?]; small circle with G, B, I, H, P; a crescent Moon sort and N between this circle and the Sun
- Centre: S, the Sun, drawn as a rayed disc
- Right: small circle with P, G, E, I, H; A, with the sign of Aries
- Bottom: small circle with P, G, D, I, H; K, with a sign sort below it [?]

Therefore, when for us it is the Vernal Equinox, the Earth is in the autumnal section, that is, under the beginning of Libra with respect to the Fixed stars, or rather with respect to the Rational Zodiac; when it is the Autumnal Equinox, the Earth is under the vernal section; and when it is the Solstice, the Earth is under the beginning of Capricorn, but when it is midwinter [Bruma], under the beginning of Cancer. So, just as the revolution of the Earth's diurnal whirling produces for us the alternation of days and nights, the annual revolution brings back the four seasons of the year, and all the variety within them, which the Sun brings in the Ptolemaic hypothesis — supposing, however, that the axis of the terrestrial Equator is inclined to the plane of the Ecliptic by 23½ degrees, at right angles to the Equator, and always parallel to itself, as we shall say below.

[Margin: How the Earth's aphelion and perihelion answer to the Sun's apogee and perigee.] Moreover, the centre of the annual, or great, orb is distant from the centre of the Sun's body, along the line of the Apsides, by as large a portion as the Eccentricity of the Sun's orb, or its distance from the centre of the universe, is supposed to be in the other hypotheses; and in this age the

greatest distance of the Sun from the Earth, that is, its Apogee, is about the beginning of Cancer, or about its 7th degree, and its Perigee about the 7th degree of Capricorn. It follows that the Sun is at apogee, that is, most distant from the Earth, when the Earth itself by its motion has come under the 7th degree of Capricorn; for then it will see the Sun under the 7th degree of Cancer, and the Earth in its turn will be at aphelion, that is, most distant from the Sun. Conversely, the Sun will be at perigee, and the Earth at perihelion, when the Earth has come to the 7th degree of Cancer, from where it will see the Sun under the 7th degree of Capricorn. [Margin: Effects of the annual orb with respect to the Sun, taken together with the Moon.] And since the Earth carries the lunar heaven with it, and the Moon goes round the Earth — now set between the Earth and the Sun, at new moons, now having the Earth between itself and the Sun, as at full moons — not only eclipses but also the other aspects of the Moon to the Sun are presented to the Earth itself just as if the Earth were at rest in the centre of the world and the Sun were carried round through its annual orb.

XVII. We should like, moreover, to set before the eyes in a special diagram what we have said about the annual revolution mixed with the diurnal, and about the Moon. From A, then, as centre — where the centre of the Sun is approximately — describe the Earth's annual orb BECD; and on its circumference, taking a centre at C, describe from it the terrestrial globe, whose Ecliptic FGOH is to lie in the plane of the great orb BECD, while its Equator FIOL is inclined to it at the angle GFI, or HFL, of 23½ degrees. Let the portion of the Earth illuminated by the Sun, that is, the diurnal hemisphere, be HFI, and the nocturnal one HOI, casting into the part turned away from the Sun the terrestrial shadow HXZI; although the diagram shows this truncated, you are to conceive it extended as far as the apex of its cone. Next draw through C, to the surface of the terrestrial globe, several straight lines marking great circles of the Earth — at right angles to its Equator if you want the position of a right sphere, or oblique if you want that of an oblique one — to serve now as Meridian, now as Horizon. Let such a line, for example, be FCO, representing the meridian of an inhabitant at F, who has midday, and of an inhabitant at O, who has midnight; and let their Horizon, at right angles to the Equator, be HCI. [Margin: The succession of the hours from the diurnal revolution of the Earth.] Since, then, the Earth turns about C, the centre of its body, toward the East, from O to H, and completes its whole revolution in the space of 24 hours, it happens that for an eye at H the Sun rises and for an eye at I it sets, while for an eye at F it is midday and for an eye at O midnight. But after three equinoctial hours the Meridian FO is turned round to the position PQ, and the Horizon HI to the position MN; and neither actually performs the office of Meridian or of Horizon, but each retains only the character common to a circle of Declination and an Hour circle. So for the eye at O, carried over to Q, it will be the 3rd hour after midnight; for the eye at Q, brought to H, the Sun will rise; for the eye that was at H, carried to M, it will be the 3rd hour

after sunrise; for the eye at M, which before had the 3rd Babylonian hour, that is, 3 hours before midday, now brought to F, it will be midday; for the eye at F, which at first enjoyed midday, turned round to P, it will be the 3rd hour after midday; for the eye at P, brought to I, the Sun will now set; and for the eye that three hours before was at I, carried to N, it will be the 3rd hour after sunset, or 3 hours before midnight. Finally, for the eye that had been at N, turned round to O, it will be midnight. And so with the other hours of the day, and the alternations of the days, according as the Horizons marked on the terrestrial globe are more or less right, or more or less oblique, to the Equator.

Diagram. The annual and diurnal motions of the Earth together with the Moon, set in the right column. A large circle, the annual orb, is lettered D (left), E (right) and B (foot); C, the centre of the terrestrial globe, stands on its upper part. The globe at C, half shaded, is divided by lines and lettered round about; from it a hatched, truncated shadow cone rises, with X and Z at its top corners. Round the globe runs the Moon's circle, with Moons, half dark, at R (in the shadow cone), V (left), T (right) and S (below). Inside the annual orb, round the Sun A (a rayed disc), run two circles carrying four small bodies.

- Shadow cone: X, Z; the Moon at R within it
- Above the globe: Q, O, N
- On the globe: H (left), I (right); L, G within; C at the centre; M, F, P below
- On the Moon's circle: V, T, S
- Inner circles round the Sun A: n and u on the outer of the two, r and m on the inner; q and p below the Sun
- Annual orb: D, E, B

Now, for the lunar system, describe from the centre of the Earth C the circle, or orbit, of the lunar heaven STRV. [Margin: The lunar phases and eclipses with the Earth placed outside the centre of the world.] In it the new Moon, set between the Earth C and the Sun A, illuminated toward the Sun but dark toward the Earth, will be able — if its latitude from the great Ecliptic, of itself or on account of the parallax of latitude, does not prevent it — to cover the Sun for the Earth in a total or partial Eclipse. At the first quarter the same Moon will appear διχότομος [Greek: dichotomos, "cut in two"], that is, bisected, at T, and will appear so to an eye at I at sunset, and nearly so to eyes not far removed on this side of I or beyond it. Then, the semicircle completed, the Moon will be at R, and will appear full of light to the Hemisphere HOI, unless a small latitude from the plane of the Ecliptic has carried it within the sha- dow of the Earth; for then it will undergo an Eclipse. Finally, at V, at the time of the second quarter, it will appear halved, and that indeed to an eye at H, at sunrise. From these phases it is very easy to understand the others. You see, then, that for these phases, or for the Eclipses of the Luminaries, it is not necessary that the Earth be at the centre of the universe, A; rather, the Sun can be there, and the Earth can be removed from that centre by a due interval, provided it carries with

it through the annual orb the system of the lunar heaven and the elementary sphere, resting on the same centre C.

[Margin: A foretaste of the phases of ♀ and ☿.] If one likes to describe from A the inner orbs of Venus, *upn*, and of Mercury, *mqr*, which the great orb contains within itself, it will at once appear how, for the eye at I, for which we have supposed the Sun to be setting, Venus at *u* appears as an evening star at its greatest digression from the Sun, and nearly horned, not yet fully halved; as does Mercury, an evening star, at *m*. But to the eye at H, for which the Sun rises, Venus at *n* will appear as a morning star, and Mercury at *r* as a morning star, both with a falcate light. In other places of their orb they will show one phase after another; but at *p* and *q* they will be wholly hidden behind the Sun.

[Margin: Station, direction and retrogradation of a kind in terrestrial bodies, by force of the Diurnal and the Annual motion.] Lastly, from these two motions — the Diurnal, by which the Earth turns about its own centre, and the Annual, by which the centre of the Earth, with the whole atmosphere and the lunar heaven, is carried toward the East — it follows that the motion which these bodies undergo daily by force of the annual motion becomes unequal by force of the diurnal motion. For the Diurnal motion of the points of the terrestrial surface, through the whole arc IOH, which is nearly the nocturnal arc, is direct and swift, and toward the same eastern quarter as the motion of the centre C; it therefore adds to the Annual motion, most of all at the point O, of midnight, where the greatest speed occurs. But in the arc HFI, which is nearly the diurnal arc, the diurnal motion is, as it were, retrograde, toward the western quarter, and subtracts from the annual motion of the centre — especially at F, the point of midday, where the greatest slowness is. Near the points H, for which the Sun rises, and I, for which it sets, the motion is nearly stationary, and the diurnal motion neither adds anything to nor takes anything from the annual motion of the centre C. For this inequality consult the Tables to be set out in chapter 22, number 1. Therefore all the points of the Earth placed outside its centre, and all earthy and watery bodies, or bodies of the thicker air, that follow the motion of the Earth, become every day once direct, once retrograde and twice stationary, and would appear so to an eye placed at A, the centre of the annual orb. [Margin: The Moon stationary and retrograde by force of the same motions.] The Moon too, in its circle STRV, is compelled every month to be once Direct, in the arc TRV — namely from the first quarter T to the second V — and swiftest at the full moon R, as regards its monthly motion combined with the annual; but from the second quarter to the first quarter of the next Lunation it becomes Retrograde, and slowest at the new moon S, while at the quarters it is Stationary. But on these stations, directions and retrogradations of the Earth and the Moon, see, if you like, what we shall say more fittingly below, in chapter 14 from number 4, and in chapter 19 from number 12.

XVIII. [Margin: Effects of the annual motion of the Earth with respect to the lesser Planets.] Furthermore, the effects of the Annual motion of the Earth with respect to the five lesser Planets, and the phenomena represented by it in a truly

wonderful compendium, are very many; and they were indicated in summary by Copernicus in Book 1, toward the end of chapter 9, where he says of the annual circuit: *For if it is changed from a solar into a terrestrial one, immobility being granted to the Sun, the risings and settings of the Signs and of the stars*, namely the heliacal, *by which they become morning and evening stars, will appear in the same way; the stations, retrogradations and progressions of the wandering stars, too, will be seen to be not theirs but a motion of the Earth, which they borrow for their own appearances.* But in the same book, chapter 10, and in Book 5, chapters 2 and 3 and chapters 21 and 26, he explains many more of their phenomena by means of the annual orb, so as to represent their second inequality, or anomaly of the orb. These have been carefully reviewed by Georg Joachim Rheticus in his *Narratio prima*; by Kepler in the *Mysterium Cosmographicum*, chapter 1, in the *Epitome of Copernican Astronomy*, Book 4, from page 542, and in the introduction to the *Commentaries on Mars*; by Galileo in Dialogue 3 on the World System; by Pierre Gassendi in Letter 2, *De motu impresso a motore translato*, and in the *Institutio Astronomica*, Book 3; and by *Philolaus* revived, published at Paris. From these I wish to list the chief ones briefly.

[Margin: The second anomaly of inequality of the Planets explained by the single Great Orb.] *First.* It has been observed that the five lesser Planets, besides the first equality [?] or anomaly, which they have in their periodic motions independently of the Sun, also have a second, and that a greater and more frequent one, depending on the Mean motion of the Sun according to the ancients, or on its True motion according to the more recent Astronomers, as was said in Book 7, Section 1, chapter 7. And since in the ancient hypothesis that diversity arises from the revolution of the Sun relative to the Planets — which is swifter than their own proper motion in Saturn, Jupiter and Mars, but slower in Venus and Mercury — that whole anomaly is accounted for by the annual approach of the Earth itself, from which [?] we observe the Planets, to the Planets, or its recession from them; and the Sun becomes the centre of the planetary system, as it is the source of motion and of light. This equipollence Copernicus indicates in Book 1, chapter 5, from the words *Quo assumpto*, etc., and in Book 5, chapter 1, where he calls the motion of the Earth relative to the Planets the *motion of commutation.* [Margin: What the motion of commutation is in Copernicus.] For he says: *Each Planet, then, has privately its own revolution of commutation — I mean the motion of the Earth relative to the Planet — which they explain between themselves. For we say that the motion of commutation is nothing other than that by which the equal motion of the Earth exceeds their motion, as in Saturn, Jupiter and Mars, or is exceeded by it, as in Venus and Mercury.* Accordingly, the Anomaly that in Ptolemy is called the motion of inequality, or of diversity, among the Alphonsines the Anomaly of the argument, by Longomontanus the Motion of the Anomaly, and by many the Anomaly of the orb, is called in Copernicus and in the Prutenic Tables the Anomaly of Commutation; and what the ancients explain by five orbs, together with the Sun's Eccentric, Copernicus represents by the single Great Orb of the Earth's annual motion. In this way

the three epicycles of the superior planets, and the two Eccentrics of the inferior ones, which Ptolemy employed to explain that second diversity, are removed.

[Margin: The annual motion of the Earth the cause of the identity of the motion of ☉, ♀ and ☿.] *Second.* A reason seems to be given why the Sun, Venus and Mercury are equal in mean motion of longitude, that is, have equal revolutions of longitude, according to that saying of Plutarch in *De placitis philosophorum*, Book 2, chapter 16: *Plato and the Mathematicians think that the Sun, Venus and Mercury are moved with equal motions.* Hence it is that the table of the Sun's mean motion also serves for computing the mean motions of Venus and Mercury. For the reason, according to Copernicus, is that these planets do not have three distinct orbs, as in Ptolemy; rather, the single annual motion of the Earth accomplishes their motion in longitude, since they are enclosed within the great orb. But because the Earth revolves round these three Planets, the dwellers on the Earth judge that the planets are carried round about them while they themselves stand immobile, and so out of one motion they make three. Pressing this point against the ancient system, Copernicus says in Book 1, chapter 10: *But what cause will those allege who place Venus beneath the Sun, and then Mercury, or separate them in some other order, for these planets not likewise making circuits separate and distinct from the Sun, as the rest of the wandering stars do?*

[Margin: The appearance of stations and retrogradations from the single annual motion of the Earth.] *Third.* A reason seems to be given why the five lesser Planets appear Stationary and Retrograde, and do not always advance Direct — which seems the greatest imperfection in celestial bodies, and which made the ancients very anxious, as may be seen in Vitruvius, Book 9, chapter 4, and in Pliny the Elder, Book 2, chapter 16, and before them in Apollonius, as we related more fully in Book 7, Section 5, chapter 3. For in the Ptolemaic system, because the motion of the superior planets on their Epicycles is in reality impeded, or that of the inferior Planets on their Eccentric orbs is tempered by the motion of another orb, the planets sometimes do not move at all beneath the Fixed stars as regards their true motion, but seem to stand still, and sometimes they go back toward the West. In the Copernican hypothesis, by contrast, a Phenomenon of this kind is a mere appearance, arising not from the object itself, that is, from the real motion of the Planets, but from the carrying of our eye along with the Earth. For since the Earth, overtaking the superior and outer Planets by its annual motion, is swifter than they are, it afterwards leaves behind it, toward the opposite quarters of the world, those it used to see ahead of it; whereas it is slower than Venus and Mercury, the inner Planets, enclosed within the great orb, and lets itself be overtaken by them against the order of the signs. So the planets seem at times to go back, and, in the passage from direct course to retrograde or from retrograde to direct, to stand still — when in reality it is the Earth that makes these changes of aspects and motions by its single motion. How this comes about we have already set out, with figures suited to the purpose, in Book 7, Section 5, chapter 4.

[Margin: The annual motion of the Earth frees the Sun and the Moon from Stations and Retrogradations.] *Fourth.* From this a reason seems to be given why the Luminaries do not appear stationary or retrograde. The cause is that the Sun is at rest, while the Earth is always moved in the order of the signs with an equal motion; and so the Sun too, into the opposite par- ts, always seems to the Earth itself to advance. The Moon, however, seems neither to stand still nor to go back, because the annual motion of the Earth is common to the Earth and to the lunar heaven; and two movable bodies that have the same motion toward the same quarters seem to be at rest with respect to each other. Hence the motion of the Earth is not discerned in the Moon, as it is in the other planets. In the Ptolemaic hypothesis, by contrast, the reason for this difference is given more laboriously.

[Margin: The variation of the Arcs of Station and Retrogradation, from the annual motion of the Earth.] *Fifth.* From the same source is drawn the reason why the progression appears greater, and the regression smaller, in the Planets nearer the Earth than in the more remote ones: that is, why the arc of direction is greater in Mars than in Jupiter, and in Jupiter than in Saturn, and likewise greater in Venus than in Mercury, while the arc of retrogradation in the same planets is smaller, as is clear from the small table set out in Book 7, Section 5, chapter 2, number 4. Conversely, it gives the reason why the alternations of stations and retrogressions appear more frequently in ♄ than in ♃, and in ♃ than in ♂, and likewise more frequently in Mercury than in Venus. The reason, namely, is that the Earth by its motion overtakes Saturn more swiftly than Jupiter, and Jupiter than Mars, whereas Venus overtakes the Earth more slowly than Mercury does. Copernicus touched on these alternations in these words, Book 1, chapter 10: *For from this it may be noticed by one who contemplates not idly why the progression appears greater in Jupiter than in Saturn, and smaller than in Mars, and in Venus than in Mercury; and why such a reciprocation appears more frequently in Saturn than in Jupiter, more rarely still in Mars, and in Venus than in Mercury.*

[Margin: The reason for the Digressions from the Sun, from the annual orb.] *Sixth.* From this it likewise appears why Saturn, Jupiter and Mars can digress from the Sun through a whole semicircle, whereas Venus and Mercury cannot digress through a whole semicircle, but far less. For the orbs of the three superior Planets lie outside the great orb of the Earth and are therefore larger, while those of the inferior Planets lie within it and are smaller, as will be plain to anyone who contemplates the system set out in number 15. But if you hold to the nature of the Ptolemaic hypothesis, then, observations set aside, no cause appears why an orb as large as the Epicycle of Mars, of Jupiter or of Saturn could not be assigned to Venus and Mercury, so that, embracing the Earth in their circuit, they could digress from the Sun through a whole semicircle.

[Margin: The size of the Epicycles and of the Equations, from the annual orb.] *Seventh.* From the same situation and motion of the Earth the reason seems to be established why in the larger orbs the Epicycles are smaller, and in

the smaller orbs larger. For in Ptolemy, if he is to preserve the prosthaphaereses of the orb, the Epicycle of Saturn is smaller than that of Jupiter, and Jupiter's smaller than that of Mars, although the Eccentric deferent carrying the Epicycle of Saturn is larger than Jupiter's, and Jupiter's larger than Mars's. That is to ask why the prosthaphaeresis of the orb of Mars is greater than that of Jupiter, Jupiter's greater than Saturn's, and Venus's greater than Mercury's. The reason is this: the nearer each of the superior Planets is to the orb of the Earth, the greater the proportion that the annual orb of the Earth bears to it, and the larger that orb appears. The true orbs of Mercury and Venus about the Sun, on the other hand, are those which the ancients took for Epicycles; and Mercury's, as the swiftest planet, is also the smallest orb. In this way the vastness of the Epicycle of Venus is removed, and that of Mars, which in Ptolemy is certainly excessive with respect to the Deferent.

[Margin: The Direction of the superior planets in conjunction (☌) and their Retrogradation in opposition (☍) with ☉, from the annual motion of the Earth.] *Eighth.* The annual motion of the Earth seems to bring with it the cause why the Superior Planets are always direct in conjunction with the Sun and retrograde in opposition — a cause Ptolemy cannot give a priori, if he is asked why he does not move the Planets, together with the Epicycle, always against the order of the signs. But through the single annual motion of the Earth toward the same parts toward which the Planets move in their orb, it follows that the Earth, when it is placed between them and the Sun — that is, at the oppositions with the Sun — leaves them behind by its speed, while at the conjunctions it has them ahead of it, slower though they are. So much for the motion of longitude.

[Margin: The annual motion of the Earth makes the Inclinations of the Planets to the Ecliptic constant.] *Ninth.* The variation of the latitudes arising from the inclination — which comes from the approach of the Planets to the Earth, or from their recession, on the Ptolemaic Epicycle — requires five different librations and variations of the inclinations. But if the Earth itself is supposed to approach them and recede from them by its annual motion, all the orbs will be inclined to the Ecliptic with complete constancy, and those superfluous librations will be removed; and so the Phenomena of the latitudes, especially in Venus and Mercury, are saved much more simply, and through an a priori cause. But see what we said in Book 7, Section 4, chapter 5, Scholium 3.

[Margin: The annual motion of the Earth is the cause why ♄ ♃ ♂ appear larger and nearer in opposition (☍) with ☉.] *Tenth.* As to the motion in altitude: through the single annual orb of the Earth, which approaches the lesser Planets and recedes from them, the reason at once appears why the three superior planets always appear largest and are perigee in opposition with the Sun, since the Earth then approaches them; and why in conjunction they appear smallest and are apogee, namely because the Earth is then at its greatest distance from them. From this it also becomes manifest why Venus and Mercury, around their evening conjunction, appear both perigee and larger — Venus especially.

Hear, moreover, what Copernicus says of Mars, Book 1, chapter 10: *For from this it may be noticed*, etc. *Moreover, that Saturn, Jupiter and Mars are nearer the Earth when acronychal than around their occultation and apparition. Most of all, Mars, when he shines all night, seems to equal Jupiter in size, distinguished only by his ruddy colour; but there,* that is, around conjunction with the Sun, *he is scarcely found among the stars of the second magnitude, recognised only by those who track him with diligent observation. All of these proceed from the same cause, which lies in the motion of the Earth.* For these and similar causes, therefore, and also in order to remove the imperfection of the Ptolemaic Equant, which begs the equality of the motions from a foreign circle, Copernicus turned to the annual motion of the Earth, as he himself admits in Book 5, chapter 2, saying: *These and similar things gave us the occasion to think about the mobility of the Earth, and about other ways by which equality and the principles of the art might remain, and the reason for the apparent inequality be rendered more constant.*

[Margin: Once the annual motion of the Earth is supposed, the motion of the Planets is simple, and does not pass through the heaven of another.] *Eleventh.* When all the motions of the Planets in longitude, latitude and altitude are considered, and the solid orbs are removed, as they must be, then in the hypothesis of a resting Earth the Planets must necessarily be led round through extremely intricate spirals — such as the one we sketched for Mars, after Kepler, in Book 7, toward the end of Section 1 — and Mars, Venus and Mercury must enter the heaven of the Sun. But once an annual motion of the Earth is supposed besides the diurnal one, the Planets describe very simple orbs about the Sun, and none of them intrudes into the region of another. No wonder, then, that the Copernicans have loved this hypothesis so dearly for so many allurements of a most beautiful and most compendious equipollence, and that Copernicus called the annual orb of the Earth, as we said, the Great Orb. It would be of greater excellence still if, as some think, it alone gave the reason for the motion of the Solar spots, the libration of the Moon, the passage of Comets, and the ebb and flow of the sea — of which below.

XIX. [Margin: Effects of the annual Motion and Orb with respect to the Fixed stars.] But although the Phenomena of the Sun and of the other Planets are saved by the annual orb of the Earth, which carries the Moon with it, the Phenomena of the Fixed stars do not seem able to be saved. For it would be necessary that, as the Earth receded from the Fixed stars through the whole diameter of the great orb (which is as great as the distance of the Sun from the Earth doubled), and again approached them by as much, the Fixed stars should appear smaller there and larger here; indeed, that the meridian altitudes of the same Fixed stars, observed from the Earth when it stands under Cancer, should appear much different from those observed when the Earth is under Capricorn. Yet no such difference has so far appeared in any phenomena. But Aristarchus — as Archimedes reports at the beginning of the *Arenarius* [*Sand-Reckoner*] — and Copernicus very shrewdly provided against this inconvenience, when they set the distance of the Fixed stars from the centre of the world so great that

the semidiameter of the great orb, compared with it, has no sensible ratio to it, and therefore shows no perceptible parallax in the Fixed stars; or (which comes to the same thing) by making the whole great orb so tiny, and the sphere of the Fixed stars so vast, that with respect to it the annual orb is like a point — by roughly the same reasoning by which the Earth itself is said to be a point with respect to the highest heaven. And this, no doubt, is the reason why Copernicus, meeting these objections in Book 1, chapter 5, said that one does right *if one denies that the Earth occupies the middle or centre of the world, and yet does not admit that the distance is so great as to be comparable to the sphere of the non-wandering stars*; and again in chapter 10: *Therefore we are not ashamed to admit*, etc., *that the magnitude of the world is so great that, while that distance of the Earth from the Sun has a magnitude clearly evident with respect to any other orbs of the wandering stars, in proportion to their sizes, compared with the sphere of the non-wandering stars it is not such as to appear: which I think should be conceded more readily than that the intellect be distracted into an almost infinite multitude of orbs, as those have been compelled to do who kept the Earth in the middle of the world.* And finally, at the end of the same chapter, confirming that distance of the Fixed stars from the constant appearance of their size and from their twinkling, he concludes: *That nothing of these things appears in the fixed stars* — that is, no variation in the apparent diameter — *argues their immense height, which would make even the orb of the annual motion, or its image, vanish from the eyes, if indeed the annual orb were viewed from the Fixed stars; for every visible thing has some length of distance beyond which it is no longer seen, as is demonstrated in optics. For that there is still a very great interval from Saturn, the highest of the wandering stars, to the sphere of the Fixed stars, their twinkling lights demonstrate; by this sign above all they are distinguished from the Planets. And it was fitting that there be the greatest difference between the moved and the unmoved. So great, no doubt, is this divine fabric of the Best and Greatest.* [Margin: Copernicus's closing exclamation on the immensity of the World.] In chapter 8, moreover, he had said that the end, or boundary, of the world cannot be known, and therefore it cannot be determined whether it is finite or infinite. And in chapter 11 he says: *Provided you remember that the distance of the Sun and the Earth has already exceeded our sight in the sphere of the fixed stars*; and in Book 3, chapter 15: *If there were a distance between the Sun and the Earth which could not be reckoned against the immensity of the sphere of the fixed stars.*

XX. [Margin: What Kepler and Boulliau added to the Copernican annual Orb and motion.] So much for the tenets of Copernicus on the annual motion of the Earth. To them Kepler and Boulliau added two other characteristics, and Kepler a third besides. For Kepler, in the *Epitome of Copernican Astronomy*, pages 538, 718 and 763, and in the *Commentaries on Mars*, chapters 5, 6, 33 and 52, and Boulliau, in Book 11 of the *Astronomia Philolaica*, theorems 2, 6, 11 and 12, taught that the line of the apsides of the Planets passes through the centre of the body of the Planet and through that of the Sun, and hence that the apsis of the Earth too is drawn through the same centre of the Sun; and that the centre of

the Sun is the centre of the universe, while the centre of the great orb is distant from it not, indeed, by the whole, but by half of the Eccentricity of the Solar orb asserted by Ptolemy or Copernicus. Next, both tried to show that the path of the Planets, and hence the orbit of the Earth, is not perfectly circular but Elliptical. Lastly, Kepler maintains that the Earth, no differently from the other five Planets, is carried round by the Sun by a magnetic virtue: while the Sun, rolled about its own centre with a roughly monthly rotation, emits from itself a certain species, or quality, which seizes the Planets as if by a hand and carries them round, according to the measure of their distance and interval — which, however, Boulliau denies. These matters have been explained elsewhere and are not to be repeated here out of place. But we must come to the third and fourth motion of the Earth.

Explicatur Tertius Terræ Motus, Declinationem Axis Aequatoris, in præcedentia se conuertentis, includens.

The Third Motion of the Earth is explained, which includes the Declination of the Axis of the Equator, turning itself against the order of the signs.

XXI. We have not yet exhausted the whole depth of the Copernican hypothesis; and the deeper one descends into it, the more talent and precious subtlety one may dig out of it. Copernicus therefore saw that a third motion (which includes within itself a fourth and almost a fifth) had to be adopted, so that, by transferring to the single globe of the Earth, from the celestial spheres, the unequal alternations of the artificial days and of the diurnal arcs; at the same time the anomaly of the precession of the Equinoxes, which others call the unequal motion of the Fixed stars, with a trepidation or libration toward East and West; and finally the anomaly of the obliquity of the Ecliptic, which others call a second trepidation, or a libration toward the sides of the world, he might represent them through a librating and nodding conversion of a single terrestrial axis. This motion he called the motion of declination, or of the convertible Inclination of the terrestrial axis, or of the reflexion of the axis against the order of the signs, with a libration joined to it. This motion is indeed most difficult for our apprehension, especially as it is entangled with the diurnal revolution of the Earth and the annual circuit of its centre, as Galileo himself admits in Dialogue 3 on the World System, Latin page 289 (for we have said that it has been translated from Italian into the Latin language) — granted that he admits that the system of Copernicus, which is arduous for our imagination, is very easy in its effect for nature itself. Nevertheless I shall try to set out this motion too as little obscurely as possible, from what has been handed down to us about it by Copernicus, Book 1, chapter 11, from the words *To this circle, which runs through the middle of the Signs, and to its surface, the Equinoctial circle and the axis of the Earth must be understood to have a convertible inclination*, up to the end of the chapter, and in Book 3, chapters 3 and 4; [Margin: Authors who have explained the Third motion of the Earth [?] more lucidly.] by Georg Joachim Rheticus in his *Narratio prima*, from the words *Third, that the equinoctial*

and the axis of the Earth have a convertible inclination to the plane of the Ecliptic, up to these: *But concerning the apogee of the Sun* — or, if you read its old edition, from column 31 to 40; by Kepler in the *Epitome of Copernican Astronomy*, from page 113 to 118; by Galileo in Dialogue 3 on the World System, from Italian page 372 to 394, but from Latin page 280 to 297; by *Philolaus* revived; and by Pierre Gassendi in Letter 2, *De motu impresso a motore translato*, from page 128 to 132 and again from page 137 to 141. Taken together, these seem to me to have embraced everything necessary for understanding this motion.

But lest the involved and disparate, rather than contrary, mixture of these motions should seem impossible to anyone, the imagination must be prepared and disposed by some likeness drawn from better-known motions. Let there be, then, in the first place, a Top AB, whose axis is CD. Suppose this top, wound round with a lash [?], as boys do, and then thrown onto the floor, describes in a slower turn, by the force of the impetus impressed by the boy's arm, the arc of a larger circle CEF; but by the force of the motion impressed by the cord it conceives a very swift spin, and before it rolls from C, through E, to F, it marks on the floor very many little circles, spirally or in the manner of a snail-shell — say at C, O, E, P, F — and indeed turning itself toward the same direction, namely from G, through H, toward K.

Diagram. A woodcut in the right column showing a spinning top drawn as an inverted cone, its point resting on a small circle at a hatched floor line; a dotted arc runs from the top leftward and down through four ringed little circles, each lettered, marking the path of the top's point across the floor.

- M, D, N (above the head of the top; D set higher): the ends of the axis as it appears multiplied by the wobble — DC, ML, NI in the text
- A (left of the rim), B (right of the rim): the top AB
- O, E, P, F (in the ringed circles along the arc, from the top leftward and down): the little circles traced on the floor
- H (lower right of the cone), K (left of the bottom circle), G (right of the bottom circle): the sense of rotation, from G through H toward K
- I, C, L (inside the bottom circle): the point C of the axis, with I and L of the multiplied axes
- R (on the floor line): in the second illustration, the axis of the wooden disc

[Margin: In this figure the little circles about C, O, E, P, F ought not to be concentric, as the engraver wrongly made them, but a spiral, or snail-shell.] Next, observe the wobbling of the axis DC, by which it totters this way and that so much that at times it seems to threaten itself with a fall; and owing to that vibration of the nodding point C and of the head, or handle, D, it seems to flicker with three-forked tongues, so that the axis can seem not single but multiple, or split into three — namely DC, ML, NI — or into more. Finally, when gravity prevails and it has fallen over, inclined to one side from the line of its centre of gravity, you will see it, as far as appearance goes, revolved in the contrary direction by its contact with the floor. By this example, then —

dissimilar in some conditions, but similar in many — you will easily understand how it can come about that the globe of the Earth slowly describes with its centre the circle of the annual, or great, orb, and yet is revolved upon itself, top-wise, toward the same eastern direction, in a diurnal spin repeated 365¼ times, while its axis nevertheless wobbles about by a certain third motion of libration and can describe either little circles or twisted garlands.

You will conceive the same thing readily in another way. Let there be a round wooden table, or wooden disc, half of which the preceding figure CEF meanwhile represents; and let a small vessel full of water be fixed to its rim, say at C. On this water let a little wooden globe float, having an iron point below and a wooden one above, opposite the iron, as if both were produced from the axis of the globule, so that the iron one is under the water and the wooden one stands out above it. Then, putting your finger into the water along the rim of the vessel, drive the globule round, and the water with it, from G, through H, to K, so that the water conceives a very swift spin; and, at once withdrawing your finger, turn the wooden disc about its axis R, but slowly, from C to O. For you will meanwhile see the water, with its many vortices, carry the wooden globe round with it in the same direction, and at the same time its wooden point nod somewhat and waver tremulously, describing a certain little orb or garland. By this example and others like it one is given to understand how easily nature, or some Intelligence, could turn the terrestrial globe round with three similar motions.

XXII. With this preparation laid down — though it is hardly necessary for stronger minds — let us now turn to Copernicus, who, in Book I, chapter II, having said that, with the plane of the great orb set in the plane of the Ecliptic, it is necessary that the Equa- tor of the Earth and its axis have a convertible inclination, at once adds the reason: *For if they remained fixed* — namely the terrestrial Equator and the axis — *and simply followed nothing but the motion of the centre, no inequality of days and nights would appear; it would always be either solstice, or midwinter, or equinox, or summer, or winter, or in whatever way the same quality of the season would remain like itself. There follows, therefore, a third motion, of declination, also with an annual revolution, but bending back against the order of the signs, that is, against the motion of the centre. And so, the two being nearly equal to each other and mutually opposed, it comes about that the axis of the Earth, and in it the equinoctial, the greatest of the parallels, look toward nearly the same part of the world, just as if they remained immobile. Meanwhile the Sun is seen to move along the obliquity of the zodiac with the same motion as the centre of the Earth, no differently than if it were itself the centre of the world — provided you remember that the distance of the Sun and the Earth has exceeded our sight in the sphere of the fixed stars:* that is, that it is imperceptible and of no sensible quantity, if viewed from the fixed stars. So that the axis and the terrestrial Equator should not, therefore, be moved along the course of the great orb, or Ecliptic, but should remain always parallel to itself, or equidistant from itself, in the situation in which it once was at the time of the first Equinox or Solstice, Copernicus

thinks it necessary that, while the centre of the Earth is carried round on the periphery of the annual orb, the axis of the terrestrial Equator should bend itself back little by little against the order of the signs, and so have a convertible inclination to the Ecliptic, or great orb, such that, if it were produced, it would strike sensibly the same parts of the world through the whole circuit of the year. Now, in order to set before the eyes, in a way, the difference of the solstitial days among themselves in the oblique sphere, and from the equinoctial days, which arises from this threefold motion, Copernicus drew, in the same chapter 11, the figure which we have described in number XVI, adding the Sun S at the centre and, beyond the annual orb EFBD, the celestial ecliptic ACLK. It is to be reproduced here.

Diagram. A woodcut in the left column: an outer circle, the celestial ecliptic ACLK, with a zodiac sign at each of its four lettered points; inside it the annual orb EFBD, with a small circle of the Earth at each of its four points F (top), B (left), E (right) and D (bottom); the rayed Sun S at the centre. Each small circle carries a diameter through the Earth's centre and the letters P, G, I, H.

- C (top of the outer circle), with the sign of Cancer above it
- L (left of the outer circle), with a zodiac sign [?] beside it
- A (right of the outer circle), with a zodiac sign [?] beside it
- K (bottom of the outer circle), with a zodiac sign [?] below it
- F (top small circle), with P above right, G left, I right, H below left
- B (left small circle), with P above, G left, I right, H below; then a small crescent-shaped sort [?] and N on the line toward the Sun
- E (right small circle), with P above, G left, I right, H below
- D (bottom small circle), with P above, G left, I right, H below
- S (centre): the Sun

[Margin: Representation of the winter-solstice day.] Let the centre of the Earth now first be at F, under the beginning of Cancer, and from it let the terrestrial Equinoctial PGHI be described, not in the plane of the Ecliptic, or of the great orb EFBD, yet so that the diameter GFI is the common section both of the terrestrial Equinoctial and of the great orb, or Ecliptic. Then draw the diameter HFP at right angles to GFI; and let the southern limit of the greatest declination of the two planes — that is, of the obliquity of the Ecliptic to the Equator, or rather of the Equator to the Ecliptic — be P, and the northern limit H. This obliquity is measured by the angle HFS on the one side and CFP on the other, of 23° 30′. With these things set out, the inhabitants of the Earth, while the Earth is at F, under C, will see the Sun S under Capricorn, making the winter turning, which the greatest northern declination H, turned toward the Sun, will display: *Since*, says Copernicus, *the declivity of the Equinoctial toward the line FS, through the diurnal revolution, turns out for itself the winter tropic, parallel to the terrestrial Equator, according to the distance which the angle of inclination contains under SFH*: or, perhaps more clearly, the line conceived immovably from the centre of the Sun to the centre of the Earth is understood, during one diurnal

revolution, to mark out on the terrestrial surface a circle parallel to the terrestrial Equator, with a declination as great as the angle SFH.

[Margin: Representation of the vernal Equinox.] Let the centre of the Earth now proceed in the order of the signs and, a quadrant completed, be at B; and meanwhile let P, the limit of greatest declination, recede by nearly as much against the order of the signs, having completed as it were a quadrant of its own little circle; and meanwhile, because of the equality of the revolutions, let the angle SFI remain equal to the angle FSB. For the diameters will remain parallel to each other — namely PFH to PBH, and GFI to GBI — and likewise the terrestrial Equinoctial will be kept parallel to itself; and these will likewise appear marked out in the highest heaven, because of its immense distance. Now, to the Earth at B, under the beginning of Libra, the Sun S will appear under the beginning of Aries, and the common section of the great orb and of the Equator will coincide in one and the same line GBIS, to which the diurnal revolution admits no obliquity of the already mentioned circles, or declination; for all the declination will be to the sides. Therefore the Sun will appear in the vernal Equinox. Still, the diameter GI will be in the common section of the already mentioned circles, and the plane of the terrestrial Equator will not for that reason coincide with the plane of the great orb.

[Margin: Representation of the summer-solstice day.] Let the centre of the Earth now depart from here, the already mentioned conditions being kept, and, a second quadrant completed, be at D, under the beginning of Capricorn; for to the Earth the Sun S will seem to enter Cancer, C. And because P, the southern limit of the declination by which the Equator is inclined to the Ecliptic, is turned toward the Sun, it will make the Sun seem to be in the opposite quarter, that is, the northern, and to run through the summer tropic, in accordance with the angle SDP, which measures the inclination.

[Margin: Representation of the Autumnal Equinox.] Finally, let the centre of the Earth go away from here and, a third quadrant likewise completed, come to E, under the beginning of Aries. For, because of the already mentioned parallelism of the axis with itself, and of the Equator with itself, the common section GEI of the terrestrial Equator and of the annual orb, or Ecliptic, will fall on the line SE, without any declination; and therefore the Sun S will seem, having entered Libra, L, to mark the Autumnal equinox.

[Margin: Another Representation of the solstitial days.] In another way, and by another diagram, Copernicus, in Book I, toward the end of chapter II, exhibits on the terrestrial globe the winter and summer tropic, parallel to its Equator on the surface of the terrestrial globe, as follows. In the underlying plane let there be the diameter AC of the great orb, and the common section of a circle erected perpendicular to this plane itself; in this circle, from the centre of the Earth placed at A, under Cancer, and at C, under Capricorn, let the circle DGFI be described through the poles. Let the equinoctial axis of the Earth be DF, the North Pole D and the South Pole F; and let GI be the diameter of the already mentioned Equinoctial.

Diagram. A woodcut in the right column: two circles of the Earth joined by a horizontal line, the diameter of the great orb; "Boreas" (North) above and "Auster" (South) below. Each circle carries diameters through its centre.

- Boreas (above the figure): North
- Auster (below the figure): South
- A (centre of the left circle), with D upper left, I right, L right on the line, G left, K lower left, F bottom
- C (centre of the right circle), with D top, N upper right (set as a reversed N), I right, F lower right
- M (on the joining line, at the left edge of the right circle), with G below it

These things posited, when the pole F turns itself toward the Sun, and the inclination of the Equinoctial circle to the great orb, or to the Ecliptic, is northern under the angle IAL, then the diurnal revolution about the axis will describe the tropic KL of Capricorn, that is, the southern parallel to the Equator, according to the distance IL, and will make the Sun appear at the beginning of Capricorn. Or, speaking more correctly, the diurnal motion about that axis will to the sight produce a conical surface, whose apex will be at A, the centre of the Earth, and whose base, KL, will be in a circle parallel to the Equinoctial itself. In the same way, but with the conditions reversed, everything will come about when the centre of the Earth is placed at C, under the beginning of Capricorn: the diurnal revolution, namely, will describe the northern parallel or tropic MN, and will make the Sun appear at the beginning of Cancer. From this it follows that, if nothing else happens to this reflexion of the axis, the axis describes on the terrestrial surface a little circle on either side, about the axis of the terrestrial Ecliptic, which is always equidistant from the great orb. Or certainly — because the terrestrial axis keeps the same situation with respect to the highest regions of the heaven — that the manner in which this retention comes about is more like rest than motion, or a certain containment and restraint, as Galileo and Gassendi have acutely noted.

[Margin: Galileo's diagram for the threefold motion of the Earth.] XXIII. The mention of Galileo opportunely suggests to us another way and another figure, by which he, in Dialogue 3 *On the System of the World*, brought this mixture of the Earth's three motions before the eye; we shall set out this figure more briefly. Let the great orb ♋, ♎, ♑, ♈ be understood as described from O, near the centre of the Sun; and let the Earth be understood as placed in turn at these four cardinal points by the annual revolution of the Earth's centre. Let its axis, produced in imagination beyond the Earth, be AB, parallel to itself in every place of the annual orb; and let the diameter of the great orb from Capricorn to Cancer be ♑ O ♋. Over this diameter, or over the plane of the great orb, let the axis AB be inclined by 23½°, that is, so that the angle O ♋ B, or O ♑ A, is 66½°. For you must conceive the axis AB, together with the line ♑O♋, in one and the same plane, which is right, or orthogonal, to the Ecliptic plane of the great orb ♋ ♎ ♑ ♈ — something Galileo represents only with

difficulty in this figure. Let the North pole of the terrestrial axis be A, above, and the South pole B, below; about this axis the Earth, by a revolution of 24 hours, describes innumerable parallels. But for clarity's sake let there now be marked on its surface the Equinoctial CD, and, parallel to it, the winter Tropic GN and the summer Tropic EF; then the Arctic circle IK and the Antarctic LM.

Diagram. A woodcut in the left column: the great orb drawn as a circle with the rayed Sun O at its centre and four straight lines running from O to four globes of the Earth standing on the orb — one at the top, one at the left (its left half shaded), one at the right (its right half shaded) and one at the bottom (shaded). Each globe has its axis A–B drawn through it and carries its parallels. The signs of the zodiac stand on the orb between the globes, with tick marks, and arrows on the upper left arc.

- Top globe: A (axis, upper right), I, E, C, K, F, G, D, N, L, B (axis, lower left), M (below, on the line from O); the sign of Libra ♎ on the globe
- Left globe: I, A, E, C, K, F, G, D, L, N, B, M; the sign of Capricorn ♑ on the globe
- Right globe: I, A, K, C, E, F, G, D (set reversed), L, N, M, B; the sign of Cancer ♋ on the globe
- Bottom globe: E, I, A, K, C, F, G, D, L, N, B, M; the sign of Aries ♈ on the globe
- O (centre): the Sun
- Zodiac signs on the orb: ♏ and ♐ (upper left), ♍ and ♌ (upper right), ♒ and ♓ (lower left), ♊ and ♉ (lower right)

[Margin: Representation of the day and Tropic of summer.] Let us now consider the Earth placed at the beginning of Capricorn. The axis AB declines from the perpendicular over the diameter of Capricorn and Cancer by 23½° toward the Sun O, and the arc IK is 47°, half of it 23½°. The Sun's illumination will therefore light up the terrestrial hemisphere exposed to the Sun, divided from the dark part by the boundary IM. This boundary will bisect the great circle CD, but will divide the other parallels into unequal parts, since IM does not pass through their poles AB. The parallel IK, moreover, with the circles enclosed within it, will remain wholly in the illuminated part, just as the parallel LM and those enclosed within it will remain wholly in the dark part. Further, since the arc IK is equal to the distance of the Tropics FDN, and its half to the half FD, and the arc from F to the Pole A is common to both, the arcs IKF and AFD will be equal, and each will make up a quadrant. And since the whole arc IDM is a semicircle, the arc FM will be a quadrant, equal to the arc FKI; and therefore the Sun O, in this place of the Earth, will be vertical to anyone standing at the point F. But because of the diurnal revolution about the stable axis AB, all the points of the parallel EF pass through the same point F. On this day, therefore, the Sun at the point of noon will be vertical in succession to all who live on the said parallel EF, and will seem to them to describe, by an apparent motion (which is really the Earth's), the Tropic that we call the

Tropic of Cancer. But for all inhabitants beyond the parallel EF, toward the North pole A, the Sun will decline from their zenith toward the south; whereas for those living on this side of EF, toward the Equinoctial CD and the South pole B, the noon Sun will decline from their zenith toward the North pole A. In this place it likewise appears that the semidiurnal arc ⋎ϐD is equal to the seminocturnal arc ⋎ϐC on the Equator CD, since the boundary of light IM bisects that circle alone; that the semidiurnal arcs on the parallels above CD, toward the North pole A, are greater than the seminocturnal; that below CD, toward B, they are smaller than the seminocturnal; and that those who are in the illuminated part — that is, in the arctic circle IK and within it toward A — enjoy perpetual day, whereas those in the Antarctic LM, and within it, are wrapped in perpetual night.

[Margin: Representation of the day and Tropic of winter.] Now let the Earth be in the diametrically opposite situation, that is, under the beginning of Cancer ♋. For it will be manifest that, since the axis AB has remained parallel to itself and has not sensibly changed its inclination, the aspect and situation of the Earth with respect to the Sun keep everything else they had in the earlier situation — in a similar way indeed, but with an opposite likeness. For the hemisphere that was dark before is lit by the Sun, toward which it is turned, and the Sun becomes vertical at noon for those living on the parallel GN; for the inhabitants of the parallel EF, on the other hand, it has declined toward the south, descending from their zenith through the whole arc ECG of 47°; and so the Sun has passed from one Tropic to the other, descending on the meridians through the said space of 47°. Further, those who dwell under the Arctic parallel IK and within it are overwhelmed by perpetual night, while those under the Antarctic LM, or within it, enjoy perpetual day; and the semidiurnal arcs on this side of the Equator CD, toward the South pole B, are greater than the seminocturnal, but beyond the Equator smaller than the seminocturnal; and to those living on the parallel EF the Sun O will seem to describe the Tropic that we call the Tropic of Capricorn.

[Margin: Representation of the equinoctial days.] Let us now look at the Earth in the figure above at the beginning of Libra ♎, from which it sees the Sun O under the beginning of Aries ♈. The axis of the Earth was understood in the earlier figures to be inclined over the diameter of Capricorn and Cancer, and therefore to lie in the same plane that, cutting the plane of the great orb along the line of Capricorn and Cancer, was erected perpendicular to it. If it is now transferred to the present figure, keeping its parallelism with itself, it will lie in a plane likewise erected to the surface of the great orb, and parallel to that plane which cuts the same surface orthogonally along the diameter of Capricorn and Cancer. Hence it comes about that the line O♎, drawn from the centre of the Sun to the centre of the Earth, turns out perpendicular to the axis AB. But the same line, drawn from the centre of the Sun to the centre of the Earth, is always perpendicular to the circle that terminates the light; therefore the circle terminating the light will pass through the poles A, B, and

the axis AB will lie in its plane. Now from the *Spherics* of Theodosius, a great circle passing through the poles of the parallels divides them all in two, that is, into equal portions; therefore the circle bounding the light, ACBD, will divide the parallels so that IK, EF, CD, GN and LM are each semicircles. The illuminated hemisphere will be the one that faces us in this diagram, and there will be the vernal Equinox for all the inhabitants of the Earth. From this we are given to understand the cause of the other equinox, the Autumnal, when the Earth is at the beginning of Aries ♈.

[Margin: Two notable points about the parallelism of the Earth's axis.] XXIV. Galileo, and also Kepler and Gassendi, add a further point. Since the terrestrial axis of the Equator remains parallel to itself through the whole circuit of the year, if it were produced at both ends beyond the Earth as far as the firmament, it would describe an enormous cylinder, or column. Each base of it would mark out on the firmament a circle as large indeed as the annual orb, but one which, seen from the Earth, would be like a point because of the immense distance of the fixed stars; and for this reason the axis of the Earth is said to look perpetually at the same part of the heaven, and to be turned toward the same point. Granted, strictly speaking, that this hypothesis, just as it does not recognise an Equator in the highest heaven, does not recognise a pole of the Equator either: the already mentioned bases could still be substituted for the poles at which the terrestrial axis would be said to look. But Galileo, using a subtler scrutiny, noticed in this same place a certain remarkable accident. For just as the axis of the Earth, keeping the same direction toward the highest sphere of the Fixed stars, brings it about that the Sun seems to us, within the circle of a single year, to be raised on the meridian through an arc of 47°, while meanwhile it exhibits no ascension on the meridian of any one and the same Fixed star, or sensible change of its declination; so, on the contrary, if the axis of the Earth persisted continuously in the same inclination toward the Sun — or, what comes to the same thing, toward the axis of the Zodiac — no change would appear in the Sun's meridian declination. The inhabitants of any one place would therefore always have the same variations of days and nights, and the same arrangement of the four seasons of the year; and so some would be forced to endure a perpetual winter, others a perpetual summer, while still others would enjoy a perpetual spring or autumn. But, on the contrary, the greatest change in declination would appear in the Fixed stars, so that on the Meridian within one year they would vary their declination through 47°, the full distance of the Tropics.

[Margin: Our explanation of the already mentioned parallelism.] XXV. And yet Copernicus explains the conservation of the axis of the terrestrial Equator, and of the Equator itself, each in its own parallelism, by a certain motion of the axis against the order of the signs; some, however, do not think this motion necessary, or necessarily to be distinguished from the other motions; and it might still seem obscure to someone what it is to carry the centre of the terrestrial globe along the track of the great Orb, or what it is for the axis and

the terrestrial Equator simply to follow the motion of the Earth's centre. So that both these doubts may be removed by us as far as possible, we say first: if the axis of the Equator, always inclined to the plane of the great orb, or Ecliptic, by 23½°, were carried round with the centre of the terrestrial globe about the periphery of the great orb in such a way that it always kept the same inclination to the axis of the great orb, it would keep neither its own parallelism with itself nor that of its Equator with its Equator, nor would it look toward the same regions of the highest heaven, but toward ever different ones. For by its annual motion it would describe either the frustum of a right cone or, if it is understood as produced, a right cone, whose axis would be at right angles to the circle that cuts the cone; and the lines of the terrestrial axis, produced further for its different situations, would cut one another at the vertex of the cone, making an angle of 23½° with the cone's axis. Therefore, if the pole of the terrestrial axis that is inclined toward the axis of the great orb were the north pole, a person who now lives under the north pole and sees above his zenith the Cynosure, that is, the pole star — or at least sees it not a whole 3° distant from his zenith — would after six months see it about 47° distant from his zenith. To make this evident, let ABCD be the great orb, whose diameter is AEC, and at right angles to it the axis of the great orb OER. Now let there be taken at A the angle EAK of 66½°, and

Diagram. A woodcut in the left column. At the left edge a vertical line carries the points F, H, P, O, T, V, X from top to bottom. The great orb is drawn as a circle with eight small globes of the Earth on it, lettered at their centres; E and O stand on its horizontal diameter between B and D. Straight lines run from the globes and from the points of the left line to the vertex K at the right, beyond which they open out to Y, R and Z. Around each globe stand the letters O and S, at the ends of its axis, and M and Q, at its equator.

- F, H, P, O, T, V, X (left vertical line, top to bottom)
- A (top globe), G, I, B (left globe), D, L, N, C (bottom globe): the eight places of the Earth's centre
- E, O (on the diameter of the great orb)
- K (vertex at the right)
- Y (upper right), R (right), Z (lower right)
- O, Q, M, S (around each globe: axis OS, equator MQ)

similarly at C the angle ECK equal to it. For when AK and CK are produced equally at both ends — on the one side beyond the point of concourse K as far as Z and Y, and on the other beyond the diameter of the great orb, KA to F and KC to X — and when the end-points F and X are joined by the straight line FOX, and the end-points Y and Z by the straight line YRZ, there will have been marked out the sides and the diameters of the bases of two right cones, namely the Cones FKX and YKZ, the former of which is cut orthogonally by the plane of the great orb. Next let eight situations of the centre of the terrestrial globe be chosen on the periphery of the annual orb: the beginning of Cancer at A, the middle of Leo at I, the beginning of Libra at B, the middle

of Scorpio at L, the beginning of Capricorn at C, the middle of Aquarius at N, the beginning of Aries at D, the middle of Taurus at G. From these points let the circle OMSQ be described, standing roughly for the globe of the Earth, in which let the Equator be MQ and its axis, at right angles to its Equator, OS. This is to be done in such a way that in every place of the Earth the terrestrial axis of the Equator keeps an inclination of 23½° to the plane of the Ecliptic, so that, produced in imagination, it meets on one side at the same point K of the axis of the great orb at which we said AK and CK meet, and is drawn from there as far as the line YZ, while on the other side it is likewise understood as produced as far as the line FX. With these conditions kept, the directing line of the axis, while the Earth is at I, will be PIK; while it is at B, OBK; at L, TLK; at N, VNK; at D, ODK; and when the Earth is at G, the directing line of the axis will be HGK; and so for the other places of the Earth. And so, because the same inclination to the axis of the great orb is kept — that is, because the lines of the produced axis meet at the same point K — the surface of a right cone will have been described at the end of the annual circuit; but neither will the terrestrial axis be parallel to itself, nor the terrestrial Equator to itself, since the axes of the Equators converge and meet at the point K. Let us now suppose that, while the Earth is at A, the eye is at the northern pole S of the terrestrial axis and sees at its zenith the Cynosure Z, set on the vertical line ASKZ, but at an immense distance. When after six months the Earth has come to C, the eye at S, remaining at the north pole, will have the line CSKY as its vertical line, and along it will see its vertical point, or Zenith, distant from the Cynosure by an angle as great as YKZ, namely 47°. For since by construction and hypothesis CAK is 66½°, and ACK as many, that is, 133° together, the angle AKC, by propositions 32 and 15 of the first book of the Elements, will be the supplement to two right angles, and so will the angle YKZ vertical to it, namely 47°; and its half, AKE, 23½°. KA or KC will therefore indeed be longer than CA, even if the figure draws it otherwise — yet not by so much that it cannot be disregarded beside the far greater KY or KZ; so that, if a straight line is drawn from A to the most remote point Y, it will be sensibly parallel to KY itself. And so, just as the whole of AEC vanishes because of the immense distance of the firmament and is like a point, so too does AK; and for the eye to be at S with the Earth placed at A, or at C, is the same as if it were at K. But first it would look toward its zenith along KZ, and afterwards along KY; therefore it would see the star Z, after 6 months, distant from its zenith by the whole angle YKZ, which we have shown to be 47°.

XXVI. Since, therefore, if the same inclination of the terrestrial axis is kept not only to the plane of the Ecliptic, or great orb, but also to the axis of the great orb itself, it is impossible for the parallelism of the terrestrial axis with itself, and of the terrestrial Equator with itself, to be kept: in order to obtain this parallelism we shall carry the centre of the terrestrial globe round through the circumference of the great orb in such a way that, with the axis produced at both ends in thought, we conceive its length on the surface of a cylinder

oblique to the great orb, and carry the axis round in the great orb along that surface. This can be seen in the following figure, in which the great orb, as above, is ABCD, and its diameter from Cancer A to Capricorn C is AC; and let this great orb cut the cylinder FAYZCV obliquely. With the Earth placed, then, at the eight already mentioned places A, I, B, L, C, N, D, G, lay its axis OAS on the side FAY of the cylinder. For if you carry the axis round, keeping it on the surface of this cylinder, you will see in every place of the Earth the axes OS parallel to one another, and therefore the Equators MQ parallel to one another as well, since their axis passes through them orthogonally. And conversely, if you keep that axis parallel to itself through the whole annual circuit, you will describe with the axis a certain cylinder, which, if it is produced further as far as the Fixed stars, will mark out at either end on the firmament a circle equal to the annual orb — namely FPV at one end and YKZ at the other — but one which, because of the immense distance, appears as a point; and therefore, whether the Earth is at A, or at B, or at C, etc., al- ways, by way of the axis OS, it will look at sensibly the same small part of the heaven.

[Margin: Whether the 3rd motion of the axis is superfluous in Copernicus's hypothesis.] This demonstration makes it plain that if someone, taking hold of the terrestrial axis by its poles, carries it round with each pole kept on the surface of the already mentioned cylinder, so that the centre of the terrestrial globe is always on the periphery of the annual orb, he will keep, by one and the same annual motion and without a third motion really distinct from it, the parallelism necessary to represent the inequalities and alternations of days and seasons. It is plain, too, that so far as this goes the reflexion of the terrestrial axis against the order of the signs is not necessary — granted that some other motion of the terrestrial axis may seem necessary to represent other phenomena, as we shall say shortly. It was perhaps for these phenomena, and not precisely for this parallelism, that Copernicus counted that motion as a third, or distinct, motion in Book I, chapter II.

Diagram. A woodcut in the left column: an oblique cylinder whose two ends are drawn as shaded lens-shaped ellipses. Eight small globes of the Earth stand along a curve through the middle of the cylinder, each crossed by its axis and its equator, with parallel lines running through them from one end of the cylinder to the other, and a vertical line through the middle.

- F, H, P, T, V (left-hand end, top to bottom)
- Y, V, K, B, Z (right-hand end, top to bottom)
- A, I, G, B, D, L, N, C (the eight globes, top to bottom)
- O, Q, M, S (around each globe: axis OS, equator MQ)

Explicatur Quartus Motus Terræ à Copernicanis adiunctus, qui tamen Copernico Tertius eſt.

The Fourth Motion of the Earth added by the Copernicans is explained, which for Copernicus, however, is the Third.

XXVII. We were saying just now that, for the parallelism of the terrestrial axis with itself — and so for representing those alternations of days and nights which the inhabitants of the oblique sphere experience — a third motion really distinct from the diurnal revolution of the terrestrial globe and from the annual revolution is not necessary, provided one carries the axis of the Earth round, while moving its centre, in such a way as to keep it on the surface of a Cylinder oblique to the great orb, on whose surface it has once been set along its length and with each of its poles. But the Fixed Stars seem to move in longitude by a certain slow progress, and Copernicus judged that this very motion, let alone the diurnal motion of the primum mobile, must be denied to the sphere of the Fixed stars. He therefore transferred the cause of this appearance to a motion of the Earth's axis, reflecting itself against the order of the signs in such a way that the annual revolution of this reflexion is somewhat slower than the revolution of the centre of the terrestrial globe. From this, he holds, it comes about that the equinoctial sections, that is, the points of the annual orb at which the equinoxes occur, become every year more and more westerly, though barely sensibly — that is, seem to regress against the order of the signs, contrary to their sequence — but that only after many years does this regression at last become known. Since, then, the apparent progress of the Fixed stars toward the East was detected through observations by Hipparchus, Ptolemy and the other Astronomers after them in no other way than by numbering their distance toward the East from the Equinoctial points on some parallel of the Ecliptic, the Fixed stars will seem to draw away from those points equally whether they themselves really move or, while they stay immovable in their sphere, the equinoctial points themselves move, but toward the West. For this reason Copernicus substituted this precession of the Equinoxes, or of the Equinoctial points, in place of the motion of the Fixed stars, referring its cause to the difference between the annual revolution of the centre of the terrestrial globe, going in the order of the signs, and the annual revolution of the declining axis, such that the axis departs insensibly from its parallelism. That is to imagine that the already mentioned cylinder, or its axis, moves little by little with its extremities P, K against the order of the signs, so that with them it describes in the sphere of the Fixed stars something like polar circles about the poles of the Ecliptic. From this you will understand those words of Copernicus, Book I, chapter II: *There follows, then, the third motion, of declination, also with an annual revolution* (understand: of the axis) *but against the order of the signs, that is, reflecting against the motion of the centre. And so, with both* (understand: motions) *nearly equal to each other and mutually opposed, it comes about that the axis of the Earth, and in it the greatest of the parallels, the equinoctial, look toward nearly the same part of the world, just as if they remained immovable.* Why he applied a limitation by using the particle *nearly*, he explains toward the end of the same chapter in these words: *We were saying, moreover, that the annual revolutions of the centre and of the declination are almost equal; for if this were exactly so, the equinoctial and solstitial points, and the whole obliquity of the zodiac, would by no means change*

under the sphere of the fixed stars. But since the difference is small, growing large only with time, it has been disclosed, from Ptolemy indeed down to us, as nearly 21°, by which those points now anticipate. For this reason some believed that the sphere of the fixed stars also moves, and accordingly they favoured a ninth higher sphere; and when that was not enough, more recent writers now add a tenth on top, yet without reaching the end, which we hope we shall attain from the motion of the Earth.

[Margin: What the Royal Road is in Kepler.] Therefore, to account both for the apparent motion of the Fixed stars in longitude, together with its anomaly, asserted [?] above all by the Alfonsines, and for the changes of the obliquity of the Ecliptic, Copernicus substituted a single motion of the terrestrial axis — but of an axis nodding with a twin libration — in place of the motion which others ascribed to the eighth, ninth and tenth sphere. How this libration of the terrestrial axis comes about, and in what way each anomaly results from it — namely that of the precession of the Equinoxes and that of the Obliquity of the Ecliptic — Copernicus sets out next, in Book 3, from chapter 3 to 6, as do Rheticus in the first *Narratio* and Kepler in Book 7 of the *Copernican Astronomy*; and we have already set it out sufficiently in Book 3, chapter 29. Kepler adds, however, that both the magnetic fibres and that animal faculty of which we spoke above concur in this motion as well; and that, in order that the variation of the obliquity of the Ecliptic and of the apparent latitude in some fixed stars may be discerned and brought back to a just measure, one must conceive in the heaven a certain mean Ecliptic, fixed in the plane of the great orb, which he himself calls the Royal Road [Via Regia]. From these things now gather the following.

[Margin: 1st Corollary.] *First*, that Rheticus, Galileo and Gassendi, who attribute four motions to the Earth, do not conflict — they do not conflict, I say — with Copernicus or Kepler, who in the places already mentioned ascribe only three motions to the Earth and call third the motion we set out from numbers 21 and 27 under the third and fourth. For the modification that the terrestrial axis receives from the twin libration, one in longitude and the other in latitude, to save the anomaly of the precession of the equinoxes and of the obliquity of the Ecliptic, they treat as a distinct motion — if not really, as they say in the schools, at least formally.

[Margin: 2nd Corollary.] *Second*, suppose a motion in longitude toward the East is granted to the Fixed stars themselves too, as even among the Copernicans Lansbergen and Boulliau grant; suppose this motion is uniform, so that there is no anomaly of the precession of the equinoxes, which I have taught to be more probable in Book 3, chapters 28 and 30, and Book 6, chapter 17; and suppose, finally, that there is no variation of the obliquity of the Ecliptic, let alone any anomaly of this variation itself, as I have likewise shown to be more likely in Book 3, chapter 27. Then no third motion will now be necessary to the Earth, and the Copernican hypothesis will be far easier both to understand and in its working. For we have already said that the diurnal and annual revolution of the Earth suffices to represent all the other phenomena, provided the annual

orb, with respect to the distance of the Fixed stars, has no sensible proportion, and the axis of the Earth's Equator is always kept in its parallelism — which, as we taught a little earlier, can come about without a distinct motion.

[Margin: 3rd Corollary.] [Margin: Praise of Copernicus.] *Third*. Posterity has never sufficiently admired, nor will it ever sufficiently admire, the loftiness of Copernicus's mind, the depth of that breast and the keenness of his genius. By the motion of one little globe (how small the Earth is with respect to the whole heaven!), and a threefold motion at that, he achieved what the greatest part of the Astronomers before him could barely sketch even with insane machines of spheres. For by the diurnal motion of the Earth he represented the primum mobile, and freed all the other Planets, and the Fixed stars too, from that motion which would otherwise have had to be carried out by vast orbs, or by circles or spirals, not without an apparent conflict with their own proper motion. In place of the three Eccentrics of the Sun, Venus and Mercury, and the three Epicycles of Saturn, Jupiter and Mars, and of their second anomaly in motion, he substituted a single orb and annual motion of the Earth; and by it he also eliminated the apparent imperfection of Stations and Retrogradations in those same planets, and the libration of their inconstant latitude and inclination to the Ecliptic. Finally, by the revolving libration of a single terrestrial axis he accounted for the proper motion of the fixed stars and the change of the obliquity of the Ecliptic, with the anomaly of each — that is, he cast three huge spheres down from the heaven and did away with them. And what so many Atlases before him could not do, this one Hercules dared to sustain. Would that he had kept himself within the limits of this hypothesis!

SCHOLIA.

Scholia.

I. Above, at number 7, we taught from Copernicus that the motion of heavy and light bodies descending naturally through the atmosphere — the part of the air full of watery and earthy vapours and exhalations — does not in reality take place in the space of the world along a straight line perpendicular to the Earth's surface, but along another line. That motion is compounded of the straight and the circular, and in these bodies the circular predominates, because the straight does not belong to them except when they are in a disordered state and carried out of their own place, whereas the circular belongs to them of itself and primarily, since it belongs to them perpetually and agrees with the motion of the whole Earth, of which they are parts. These things, I say, Copernicus taught in Book 1, chapter 8, and Galileo in Dialogues 1 and 2 on the system of the world. But of what figure and kind that line is, along which they so ascend or descend, Copernicus did not determine; Galileo, however, taught that it is circular, as I shall set out more fittingly in chapter 17. There I shall also explain the opinion of Boulliau, who holds that this motion is mixed of two circular ones, and I shall show their error in the same place, numbers 16, 17, 18.

[Margin: Error of an unnamed author about the serpentine line of heavy bodies descending.] II. What Kepler thought, he himself disclosed in a few words in Book 1 of the *Epitome of Copernican Astronomy*, page 132. There he first rebukes someone or other who affirmed, with too little consideration, that the fall of a stone toward the Earth fluctuates this side of the perpendicular or beyond it in serpentine windings, so that the number of windings answers to the gyrations of the Earth. Against this assertion he observes that the stone, left behind by the parts of the Earth over which it hung perpendicularly at the start, comes to be swept along by the neighbouring parts that follow, its fall always deflected toward the quarter into which the Earth turns — little indeed at the beginning, more and more at the end — because the sweep of a near carrier is the stronger. For he holds that heavy bodies tend to the Earth by a mutual magnetic force, so as to be united with it, and are seized or drawn by the Earth so that it may unite them to itself for the preservation of its whole globe.

[Margin: Figure of the descent of heavy bodies according to Kepler.] III. Having eliminated this error, Kepler at once adds in the same place that if some heavy body were to fall from a very remote place of the heaven, A, toward the Earth rotating in one fixed place, the figure of its motion would be roughly this one, which he admits he has drawn roughly in the first part of the attached diagram. In it the Earth's circle is divided into 24 parts, and the line of fall, AEF, into as many, but unequal ones, short above and longer below; and the parts of the circle, each in its own order having already discharged its office of drawing, have already returned to their places; but, for example, only three, overtaken by the fall of the heavy body, did not draw it perpendicularly at the end of the fall. So the figure of the already mentioned fall, as it approaches the Earth, seems roughly to imitate a parabolic line. But Kepler's error will become manifest from what is to be said in chapter 17, numbers 16 to 18.

IV. Pierre Gassendi, however, at the beginning of Letter 2 *De motu impresso a motore translato*, teaches that such motions, which seem to us perpendicular whether in descent or in ascent, are in reality parabolic in the space of the world. [Margin: Gassendi's opinion on the figure of the already mentioned[37] motion.] He uses, however, a heavy body thrown straight up, and the following figure — which we, however, have drawn more like a parabola. Let there be, then, a Tower AB, from whose foot A an iron ball is fired straight up from a musket, and let us suppose that, so far as our sense experiences it, the ball reaches the top B. Now if the Earth did not move at all, it would at once fall back from B to A along the perpendicular once its ascent was complete. Let the Earth now move from A, a western point, toward K, an eastern one, and the Tower together with it, and let the spaces the Tower occupies in its motion be marked at equal intervals: let these be CL, DN, EP, FR,

Diagram. A woodcut in the right column, in two parts side by side. On the left, Kepler's figure: a line of fall marked with dots runs from A at the top

[37]printed *pra-dicti*

through E down to F on a circle whose rim is ticked off into small divisions; C stands at the top inside the circle, B at its centre and D at its foot, with a short unlettered stroke inside the circle to the left of B. On the right, Gassendi's figure: a base line and a top line joined by nine verticals (the successive stations of the Tower), and a curve rising from A at the bottom right to R at the top and falling to K at the bottom left.

- A, E, F (the line of fall, top to bottom); C, B, D (the circle: top, centre, foot)
- K, I, H, G, F, E, D, C, A (the base line, left to right)
- β, Y, V, S, R, P, N, L, B (the top line, left to right)
- M, O, Q, R, T, X, Z (the curve, from A up to R and down to K)

GS, HV, IY, Kβ. When the ball reaches the top of the Tower, let the Tower itself already have completed half, AF, of the interval AK, and be at FR; and let it pass through the remaining half, FK, while the ball descends from the top of the Tower to its very foot. On these suppositions Gassendi affirms that, granted the Earth moves, the Tower carried from AB to CL would still leave the ball behind if the one who throws it did not cleave to the Earth itself at A — in the same way as, if someone standing outside a moving ship, on the nearby shore, were to fire a ball straight up from a musket while the ship's mast passes [?] opposite him, a ball of this kind would not follow the mast but would be left behind by it. Conversely, if the one who throws that ball along the height of the mast cleaves to the moving ship, the ball follows the mast and is not left behind by it, because he impresses a mixed impetus on the ball: mixed, that is, of the impetus that the fire impresses upward and of the one that the motion of the ship and of the sailor, as of a single mover, impresses on the ball crosswise. So too, since the one who throws the ball upward from A cleaves to the Earth running from A toward K, and is one mover with it, he impresses on the ball a motion mixed of the straight one upward and of the circular, or quasi-circular, one crosswise toward C; it follows that the ball is nowhere left behind by the Tower.

Now a ball thrown from a ship along the mast describes to the eyes of the sailors, in ascent as in descent, a straight perpendicular line, and the sailors in the same ship can notice no other figure of curvilinear motion, because that transverse motion is common to them and to the ball (when two Movables are moved with equal or similar speed toward the same quarter, neither seems to the other to change place, but to stay in the same place opposite the other); and yet in reality that ball is moved along a transverse and curvilinear path very like a parabola, as those notice who stand on the shore and are not moved with the motion of the ship. Just so, assuredly: the motion of the ball thrown upward from the foot of the Tower, A, by a mover standing on the Earth itself — which meanwhile runs from A toward K through C, D, etc. — is mixed of perpendicular and horizontal. By the proper force of the man throwing it, the ball is fired upward as far as the top of the tower; by the force of the motion of the Earth carrying the tower from A to F, it gets from A as far as R; and then,

by the force of the same motion, from R to K, where the Tower arrives once the other half of the interval is completed. And so that ball describes a parabolic line in the space of the world, namely the line AMOQRTXZK. For when the Tower is at CL, the ball has ascended to M; when the Tower has been carried to DH, the ball has ascended to O; and when the Tower has been advanced to EP, the ball has been carried up to Q; and when the tower has been carried over to FR, the ball reaches the top R. Soon it is to descend, and by a like descent it glides down from R through T, X, Z to K. Granted, neither the man who threw the ball up nor the bystanders clinging to the Earth would notice that transverse motion, since it is common to them and to the ball, equally swift, and made toward the same quarter of the world; and so the ball would seem to them to ascend and descend with a merely rectilinear and perpendicular motion.

[Margin: Anticipation of an objection, and its solution.] V. "You will say," Gassendi says in the same place, "what if someone were held in the air inside a chest carried off by a griffin? Would he notice the parabolic motion of the ball?" He answers: by no means, because according to the Copernicans he too, together with the griffin, the chest and this lowest air, is carried toward the East by a common motion — just as, when a quince is rolled round, its down is rolled round with it, and any little creature, say an ant, held within that down. He admits, though, that because of its fluidity the air does not cohere so firmly with the terraqueous vapours and exhalations, and so resists ever so slightly its being swept toward the East, and therefore seems to move gently toward the West; and that from this come those breezes of the surrounding air in open plains and on the Ocean within the torrid Zone, [Margin: The perpetual wind within the Tropics toward the West.] where the motion of the Earth toward the East is more vehement, while the resistance of the purer air toward the West appears greater and is felt far more evidently than in valleys or in the slower parts of the Earth near the poles. We said in the preceding chapter, number 6, that this very thing had been noticed earlier by Galileo; about this wind I remember reading in Ramusio's *Navigations* and in our own José de Acosta. Gassendi adds, as does Galileo in Dialogue 2, that just as, when there is inside a moving ship a vessel full of water with live fish swimming at will in that water, or the ship's cabin is full of birds, flies, etc., the motion of the ship in no way hinders the proper movements of the fish turning in every direction; nor, if you jump toward one side on the ship's deck, do you gain more or less space in the ship than if the same things were done with the ship standing still: so neither does the common motion of the atmosphere hinder the proper flights of birds, flies, etc., nor the particular blasts of the winds that drive clouds, straws and shavings. Since, however, the ball spoken of in scholium 4, when it begins to descend from the top R, has no impetus impressed on it by the Earth, nor perhaps by the air — or not as much as it had before from the Earth — but is moved crosswise only by the motion common to all terrestrial things, it is

therefore probable in this hypothesis that it will descend somewhat sooner from R to K, or rather between K and I; but by a difference imperceptible to us.

[Margin: A heavy body let fall from the mast of a running ship descends perpendicularly to the foot of the mast.] VI. Gassendi seems to suppose as certain that a stone thrown straight up by a sailor along the length of the mast, or let fall by a man at the top of the mast, descends perpendicularly to the same place in the ship. Lest you think he supposed this without grounds, consult his earlier letter on motion impressed by a transferred mover, written to Petrus Puteanus [Pierre Dupuy]. For there, from page 15, he relates as from a certain experiment that if someone goes out on the Seine in a skiff, with the current, the boat being driven by oarsmen as well so that it is carried with the greatest speed possible, and throws pebbles straight up from the prow, they fall back to the prow; if from the stern, to the stern; if from the middle of the boat, they likewise slide back to the middle. And although to those carried along in the same boat the ascent and descent of the pebble seems to be made perpendicularly, because they are borne by the same common horizontal motion, to those standing on the shore it was seen to describe a parabolic line, begun upward from the place of projection and ended at the place of the fall. Galileo asserts the very same of a heavy body let fall from the mast of a ship, whether moving or unmoving, which in either case slides down to the foot of the mast, in Dialogue 2 on the system of the world, Latin pages 104 and 111. He asserts it against the obstinate imagining of certain people who hold, without any experiment, that if the boat stands still the body falls perpendicularly to the foot of the mast, but if the boat moves swiftly toward the East, that heavy body will fall far beyond the foot of the mast toward the West; among these were Tycho, in the *Epistolae Astronomicae*, page 190, and Chiaramonti, in his defence of the *Antitycho*. Indeed he adds that if, with the boat at rest, a stone torn from the top of the mast, or let fall by a man clinging to the very top of the mast, comes down in the time of two pulses of the artery, and the boat is then moved so swiftly that within the same time it advances 20 cubits, that stone will still fall to the foot of the mast, and in no longer time than two pulses of the artery — although in the second case it has run through a much longer path, because the length of the space to be traversed was compensated by the greater speed, owing to the motion impressed by the mover, who is one with the moving ship.

[Margin: Notable points about motion impressed by a transferred mover, from Galileo and Gassendi.] VII. I now pass over many other experiments, though otherwise worth knowing, and admirable effects of mixed motion — that is, of motion impressed by a mover while he too is carried along, either by himself or by another — which are pursued at length by Galileo in the said Dialogue 2, from Latin page 113, by Cabeo in Book 1 of the *Meteorologica*, text 17, from question 2 to 10, and by Gassendi in the earlier of the already mentioned Letters. To our purpose I add only two, more worthy of note. The First concerns a ball thrown by a man who is being carried along in a chariot.

Tell the driver to urge on the horses and slacken the reins, and then you, who sit or stand in the chariot, throw a ball straight up with as great an impetus as you wish or can: it will fall back into your hand, if you want to recover it, for that ball follows you as you run along. The reason is that, besides the upward impetus put into the ball by the force of your arm considered by itself, you also impressed on it an impetus of horizontal motion crosswise, by the force of the motion of your whole body, with which you were being carried along together with the chariot. [Margin: Motion of a ball thrown upward by one who is running.] To you, indeed, who are swept crosswise with an equal motion, the ball will seem to describe a rectilinear and perpendicular motion as it rises and falls back; but to another, who is at rest on the road and not carried along by the same motion of the chariot, the ball will manifestly appear to describe a forward, curved and parabolic path, roughly like the line ARK marked above in the last diagram. The same thing, but downward, will happen if you let a ball drop from the speeding chariot: it will seem to you to fall onto the point over which your eye stands perpendicularly; but one who is outside the chariot will see it carried forward and falling to the ground along a curved path. [Margin: The art of those who strike birds while they fly.] The Second is the experiment, or art, of those who go after flying birds with a musket with such skill in aiming that they mostly hit them and bring them down. For, observing the bird's course and path and its speed, whether it flies toward them or away from them on an opposed or a following course, they swing the barrel, or iron tube, while firing the ball or the lead shot; and by that swing an impetus is impressed on the ball mixed of the straight one upward, by the force of the fire, and the transverse one, by the force of the swing of the arm and of the musket. So the ball either catches up with the fleeing bird or anticipates it as it flies toward them. And this, finally, is why one who leaps down from a speeding chariot falls, and why wine or water bursting from the pipe of a cask, and the ball of a bombard, fall to the ground along a parabolic line: namely, because of the motion impressed by a twofold mover or moving force — the perpendicular motion, downward, from their native gravity, and the transverse motion from the fire, or from the upper parts of the wine or water driving the lower ones out through the horizontal pipe. What I have said about the ball of a bombard and its parabolic fall, our Cabeo also observed in the *Meteorologica*, Book 1, text 17, question 4.

[Margin: The truth of the parabolic path, and the proportion in its speed.] VIII. That the line of heavy bodies thrown upward by a direct effort and sliding back downward is therefore parabolic, if the Earth moves with the diurnal motion, seems to have been sufficiently proved by Gassendi from a similar experiment of a shot or ball thrown up from a chariot or from a ship, but with a spectator outside the chariot and the ship observing the path of ascent and descent. As to why, in ascent, it completes in equal time a longer path near the beginning, such as AM, than near the end, such as QR, and conversely, in descent, RT is shorter than TX, etc.: the cause is that at the beginning of

the ascent the thrower's upward impetus is stronger and predominates over the transverse impetus; but when the ball has reached the top R, the impetus by force of gravity begins to move it downward, sluggishly at first, but more intensely at the end. More, however, is to be said of this figure below, in chapter 17, numbers 16, 17 and 18, where we shall inquire into the figure of this line from other, firmer arguments; for many things will have to be supposed there from our own experiments, not to mention Galileo's, on the descent of heavy bodies and the increase of their speed, which would be inserted here too inopportunely.

CAPVT V.

Chapter 5.

Proponuntur & Diſſoluuntur Decem Argumenta pro Reuolutione Diurna Terræ,deſumpta ex Terræ ipſius conditionibus Collatis cum Octauæ aut ſupremæ Sphæræ conditionibus.

Ten Arguments for the Diurnal Revolution of the Earth, drawn from the conditions of the Earth itself Compared with the conditions of the Eighth or supreme Sphere, are Proposed and Resolved.

[Margin: A very necessary admonition.] I. What I have resolved to observe, with the whole effort of my mind, in this so celebrated and arduous controversy, I would like to obtain from the Reader as well: namely, that all the arguments which are usually brought, or will seem capable of being brought, for the motion of the Earth or against it, be weighed with the fairest balance and a sincere disposition toward the truth, and that as much weight be given them as possible; that the arguments be unfolded one by one, since very many of them, often heaped together as if in a single sorites, confuse the mind; and that, with the prejudice of a presumed opinion set aside, the replies to the arguments be weighed with equal indifference, the final and decisive verdict being held back until the very end of this disputation. For this reason I shall not be reluctant to compress the arguments, once collected, into syllogistic form wherever it is needed.

I. Argumentum à Figura Terræ, vbi obiter de Figura Cæli.

1st Argument, from the Figure of the Earth; with, in passing, the Figure of the Heaven.

II. Copernicus led the way for the others in this argument, in Book 1, chapter 8, in these words: *Whether, then, the world is finite or infinite, let us leave it to the disputation of the natural philosophers [Physiologi], holding this as certain: that the Earth, enclosed by its vertices* — that is, enclosed by mountains — *is bounded by a globular surface. Why, then, do we still hesitate to grant it the mobility that by nature suits its form, rather than that the whole world, whose limit is unknown and cannot be known, should slide round?* It is as if he said: if the diurnal motion of the primum mobile must be granted to one of two bodies, namely either the

Earth or the supreme heaven, which contains the whole world in itself, it is to be attributed rather to the body which is certainly known to have a spherical figure — the figure that by its nature is the most apt for the motion of rotation [motus vertiginis], because it lacks angles — than to the one whose figure is unknown. But it is certainly established that the Earth, notwithstanding the very slight roughness and height of its peaks or mountains, is spherical on every side, as is plain from what we said in Book 2, chapter 1; whereas the supreme heaven was thought spherical by the Stoics, in Plutarch, Book 2 of the *De placitis*, chapter 1; by Pythagoras and Plato, in Laertius's *Lives*; [Margin: Whether the heaven is spherical or not is uncertain.] by Cleomedes, Book 1 of the *Cyclical Theory*; by Pliny the Elder, Book 2, chapter 2; by Aristotle, Book 2 of the *De caelo*, chapter 4; and by Ptolemy, Book 1, chapter 3. But the arguments of Aristotle, Cleomedes, Pliny, Ptolemy and others that are brought for its roundness are only probable arguments: such are those from the mobility, capacity and dignity of the spherical figure, or from a certain likeness to the divine Immensity, from empty space, etc. Those drawn from circular motion, moreover, fight only for concavity, not for convexity, and already involve the very thing we are now calling into controversy. And so the argument drawn from there for the finite extent of the outermost heaven and of the world has no force in the present question. Nor, again, is it plain from the sacred scriptures that the last heaven is round on every side as to its outermost surface. For those words of Ecclesiasticus 24, *I alone have compassed the circuit of heaven*, and *All things that are contained in the compass of heaven*, can be understood of the concave surface of the visible heaven, or of a circuit taken broadly for a boundary closing off some space on every side — in the way someone is said to have gone round a whole city even if it happens to have a square figure. [Margin: Opinions of the Fathers on the figure of the heaven.] For this reason the heaven was held to be only hemispherical, or spread out over the Earth like a vaulted chamber and arch, or a tent, by Saints Justin, questions 59 and 130; Basil, Homily 1 on the Hexaemeron; Ambrose, Book 1 of the *Hexaemeron*, chapter 6; Chrysostom, *On the Incomprehensible* [?] *Nature of God*, chapter 2; likewise Theophylact and Primasius on the Epistle to the Hebrews; Theodoret, in his book *On Matter and the World*; Lactantius, Book 3 *On False Wisdom*, chapter 24; Euthymios Zigabenos on Psalm 103; and Procopius, Severianus and Acacius on chapter 1 of Genesis. Indeed St Augustine, in Book 2 of the *De Genesi ad litteram*, chapter 9, doubted whether it was not rather a human fiction of those who say the heaven is spherical on every side, though he afterwards grants it — to say nothing of the profane authors who, in Plutarch, Book 2 of the *De placitis*, chapter 2, gave the World the figure of a top, or of an egg, or some other figure different from the spherical. Many other Fathers, however, favour the roundness of the heaven: above all St Nazianzen [Gregory of Nazianzus], Oration 4 against Julian, with Elias the interpreter there, and the oration on Holy Baptism, with Nicetas there; St Hilary on Psalm 135; St Ambrose, sermon 12 on Psalm 118; St Jerome, Book 11 on Isaiah; St Augustine on Psalm 103, and Book 1 of the *De Genesi ad litteram*,

chapter 20, and Book 2, chapter 9; Bede, in his book *On the Creation of the Six Days*; and with them Alensis, part 2, question 50, and the Scholastics on Book 2, distinction 14. Whatever may be said of the Empyrean, which some have thought round and some square or cubic, as I said in this Book 9, section 1, q. 6, chapter 1, number 31 — for there we taught that it is held to be immobile, whereas we are speaking of the heaven that is held to be mobile, at least as to appearance — even if the world is supposed finite, it is still uncertain whether it is spherical on every side; how much more so if it is uncertain whether it is finite or not. For that it is not infinite cannot be demonstrated by any natural arguments, since we once maintained in our Physical disputations that an actually Infinite magnitude can exist; and that figure is incompatible with an infinite body, as being what terminates and bounds it, is affirmed by so many that they cannot be convinced of the opposite. But we have digressed enough on the occasion of this argument, which — from the spherical figure of the Earth, though in very few words — was used by William Gilbert, Book 6 of *De magnete*, chapter 3; by Kepler, in the *Epitome of Copernican Astronomy*, page 110; by Origanus, in the dedication of his *Ephemerides*; and by Gassendi, Letter 2 *De motu impresso*, page 112. I am truly surprised that Gassendi counted this argument among the necessary ones, saying: *It seems worth considering that, if the Earth had been constituted by its own nature for rest, it would no doubt have been given either a pyramidal or a cubic form, not, as it has, a round one; for which reason, as this form is most fitted for motion, so the Earth seems to be moved wholly by its own nature.*

[Margin: Anticipation of an objection.] III. Nor should you say that this argument infers more than the Copernicans would wish: namely, that all the bodies of the world which the Copernicans would grant to be globular — such as the whole elementary sphere and the globes of the Planets and Fixed stars — must be moved with a motion of rotation about their own centre. For they will answer either by granting them this rotation, so that they likewise have in it a cause of the twinkling in the very distant Fixed stars, or by granting it for other causes, for which this rotation has been admitted by some in all the planets except the Moon, as we said in Book 3, chapter 4, and Book 7, section 1, chapter 3, scholium 3, and chapter 7, number 12. In the Moon, however, it is not admitted by those who move her by a simple Eccentric, because otherwise she would not always turn the same spots toward us in the same quarter; and conversely, because of this very appearance, the motion of rotation must be admitted by those who think she is moved by an Epicycle carried by an Eccentric. As for the whole elementary sphere, they will deny that the diurnal motion must necessarily be attributed to one of the two — namely either to the Earth or to the supreme air and fire — and deny that the sphere shares with the Earth in this hypothetical necessity that the motion be attributed at all events to one of them.

[Margin: The hypothetical form of the already mentioned Argument.] IV. The form of the already mentioned argument, then, can be either hypothetical

or categorical, that is, absolute. The hypothetical form is of this kind: *If the motion of diurnal rotation must necessarily be attributed either to the Heaven or to the Earth, it is to be attributed to the Earth rather than to the heaven. But the motion of diurnal rotation must necessarily be attributed either to the heaven or to the Earth; therefore etc.* The MAJOR premise has now been sufficiently established, because such a motion is to be attributed rather to the body that is certainly known to have a figure suited by its very nature to this rotation than to the body that either does not have such a figure or of which it is not certainly established whether it has it or not; and it is certainly established that the Earth has such a figure, whereas about the heaven there is doubt. The MINOR premise is sufficiently plain, because the world is divided exhaustively into the heaven and the Earth, some of the Elements being included under the name either of the heaven or of the Earth, and the celestial bodies under that of the heaven; nor does it appear to what other body the daily appearance of the diurnal rotation could be ascribed.

[Margin: 1st Reply to the Argument.] V. One can reply, first, by Conceding the Major and its proof on the supposition that this motion necessarily takes place through the rotation of some body — that is, through a motion of that body about its own centre, really distinct from its other motions — but by denying it if the motion does not necessarily take place in this way, and its appearance can instead be saved by a total translation of a body from one place to another; and by holding that the diurnal motion, which is called that of the primum mobile, can be attributed both to the individual globes of the Planets and to the individual fixed stars, carried round through a fluid heaven by their own movers one by one, without any rotation of the Heavens by whose motion they would be moved. But since it is more probable that the Planets are indeed moved in this way, but the Fixed stars by the motion and rotation of the eighth sphere, or at least together with the rotation of the Firmament, rather than each of the non-wandering stars individually in a liquid heaven, as we said in section 2, chapter 3 — for this reason:

[Margin: 2nd Reply.] VI. It is replied, *secondly*, by Conceding the major proposition and its confirmation if all other things are equal, but denying it if they are unequal, and if other reasons outweigh, or at least equal, this reason taken from the aptitude for the motion of rotation that comes from the roundness of the figure. Moreover, from all the arguments that we shall bring below against this diurnal motion of the Earth — at least taken together — there arises a reason that outweighs the one we were speaking of, or is equivalent to it.

[Margin: 3rd Reply.] VII. It is replied, *thirdly*, by Denying the Major; and, as to its proof, by conceding it if that aptitude arising from the figure were necessary for rotation, so that what lacks it would be wholly incapable of rotation, or were indeed useful, but ordained for that purpose per se or principally; otherwise, however, by denying the major of the proof. Now the spherical figure was not necessary for this rotation: for the diurnal motion did

not have to take place over some plane, nor within some solid body that would resist the enclosed moving thing if it were angular, but either in the air, or in the liquid aether, or in the ethereal breeze [aura aetherea], none of which resists. Nor, moreover, was this figure bestowed by God on the terraqueous globe for this as its principal end, since it was not granted for this end at all, as those who deny it this motion must say; but so that, its bulk and weight being balanced on every side, it would keep its equilibrium — and indeed the equilibrium of the Seas, lest otherwise the waters, not equally distant from the centre but some higher than others, should rush headlong to the lowest places; and so that living creatures, especially human beings, might enjoy the view of the whole celestial hemisphere, and the globe might lie open to the celestial influences equally on every side and in an orderly succession round its circuit; and for many other reasons which there is no need to list one by one. This is all the more so since I am quite certain that the Copernicans, even if the Earth were not round at all, would not on that account deny it the diurnal motion; and consequently the rotation is not rightly denied to the Eighth sphere even if it is not certain that it is round on the outside — granted that, if this rotation is conceded to it, its roundness may not improbably be confirmed from it. And from this the reply to the already mentioned Argument can be plain, if it is put forward without the hypothesis.

[Margin: The absolute form of the Argument, and the Reply.] VIII. For it could be said absolutely: *Of two bodies, the diurnal revolution is to be attributed rather to the one that is certainly spherical than to the one that is not spherical, or is not certainly established to be so, etc.* For any of the three replies already brought can be applied to this major proposition, but especially the second and the third.

II. Argumentum à Mobilitate Terræ raptilis ad motum Primi Mobilis.

2nd Argument, from the Mobility of the Earth, liable to be carried off [raptilis] by the motion of the Primum Mobile.

[Margin: The Argument of Mästlin and Kepler.] IX. "Not without reason" (these are Kepler's words in the *Epitome of Astronomy*, Book 1, page 106) "does Mästlin also ask this, namely in his preface to the *Narratio prima* of Rheticus: how can it happen that, when the whole system of the World is carried round — none of its orbs being excepted, not the sphere of fire (if there is one), not the upper Region of the air — this single little globe, whose diameter is less than one twenty-thousandth part of the diameter of the world, is not carried round together with it?" *How can it be*, says Mästlin, *that, when the whole system of the world is carried round, this single little point is not turned?* [Margin: And Galileo's [?].] But Galileo states this same point still more explicitly in his 7th objection [instantia], which he brings for the diurnal motion of the Earth in Dialogue 1 on the system of the world, page 86 of the Latin. For he says: *If we attribute the diurnal turning to the highest heaven, we must give it such great power that it carries with it the innumerable multitude of fixed stars, all of them very vast bodies and much larger than the Earth, and besides that all the spheres of the Planets, although both the*

latter and the former move by their own nature in the contrary direction. Moreover, we must also concede that the Element of Fire and the greater part of the air are carried round with them, and that only the small globe of the Earth resists such great power with stubborn rest. This in my judgement involves much difficulty; nor can I see how the Earth — a suspended body, balanced equally on its centre, indifferent to motion and rest, surrounded by an ambient liquid — should not itself also give way and be carried round together with the rest. But we find no such obstacles if we attribute the motion to the Earth, a very small body, insensible with respect to the Universe, and therefore unfit to do the Universe any violence. In these words, however, many things are involved and presupposed that belong to other arguments to be discussed later. In this place we weigh only the argument drawn from the mobility of the Earth, given the motion of the primum mobile. So that it may have its full edge, I put it into form as follows.

[Margin: The Argument reduced to form.] X. *If, of two movable bodies, one stands in such a relation to the motion of the other that, when the other is moved antecedently and about itself, it too must necessarily be moved, because it cannot resist that body's motion, while the other does not stand so, but can rest when the first is moved, then the motion is to be attributed rather to the movable body that does not necessarily draw the other's motion along with it. But if the heaven is moved with the diurnal rotation, the Earth must be carried off by the same rotation; whereas if the Earth is moved antecedently with the diurnal rotation, the heaven need not be carried off by the same rotation. Therefore the motion is to be attributed to the Earth rather than to the heaven.* The MAJOR premise of this Syllogism seems evident, lest motions be multiplied in nature in vain, and what can be done by fewer means be done without necessity by more. The MINOR premise seems already proved, both from the comparison of the heavens and the upper elements, which in the opinion of the Peripatetics cannot at all resist the motion of carrying-off [motus raptus], and, absolutely, from the smallness of the Earth, its indifference to motion and rest, and the absence of resistance from what surrounds it.

Nevertheless I reply very briefly: Granting the Major, I deny the minor proposition. For it is not necessary that, when the supreme heaven is moved, the Earth be moved and carried off; on the contrary, given a diurnal motion of the heaven such as appears to us, the Earth must rest, or not be moved with a sensible diurnal motion. For, *First*, it is more probable that the heaven of the Planets is liquid, which Kepler and Galileo themselves concede, as we taught in section 1, chapter 7; and consequently that the ethereal breeze adhering to the concavity of the Firmament is carried off by its motion in such a way that, through the breeze's own thinness, that motion at length dies away in the lower parts and is not sufficient to carry the globes of the Planets with it; and so the heavens of the Planets are not stirred by that motion, nor is the fire in the concave of the Moon carried off by it, much less the air or the Earth. Indeed, since we are dealing here with the controversy of a necessary argument — for Galileo supposes it to be such — it is not at all improbable, much less

impossible, that even the Fixed stars themselves are moved individually as in a liquid aether; and consequently far less danger of being carried off threatens the lower heavens and the elements. Besides, a Primum Mobile can be admitted in many other ways that communicates the impetus or pattern of its motion to the lower bodies without carrying them off, as is plain from the opinions brought in section 2, chapter 3. *Secondly*, even on the view of Aristotle, who admits solid heavens and the motion of carrying-off, that motion not improbably grows so faint from the fire to the air that it hardly reaches the middle region of the air, much less the lowest, because of the thinness and fluidity of these elements. For it is now well enough established, Galileo himself insisting on it, that the lightest feathers and straws are most unfit to receive impetus; how much more unfit, then, is the air? On the other side, the Earth is very dense and very heavy in all its parts, which strive towards the centre; and although heaviness of itself resists only a straight motion upward, yet, joined with density, it cannot be moved except by an enormous impetus extending through its whole depth — an impetus such as the air immediately surrounding it, affected by no sensible motion of carrying-off, cannot impress on it; nor is the Earth of itself indifferent to motion and to rest, as Galileo gratuitously supposes. Therefore it is not necessary that the Earth be carried off by the motion of the primum mobile.

I said, moreover, that it is rather necessary that the Earth not be carried off by the diurnal turning, given the phenomena that appear to us, because if the Earth were carried off by it we should always see the Sun, or the same star once seen, in the same circle of position — the Meridian, say — except in so far as they recede eastward by their slight proper motion; for we would follow their diurnal motion at an equal pace. Galileo, then, who in those dialogues so strictly demands the forms of consequences from others, ought to have been on his own guard, and not have asserted so readily as necessary what we have already shown to be not at all necessary.

III. Argumentum à Circulari Motu congruente per ſe potiùs quàm Recto Elementis, atque adeò Telluri.

3rd Argument, from Circular Motion as befitting the Elements per se rather than Straight motion, and so befitting the Earth as well.

XI. This argument too is *ad hominem*, as they say in the Schools, and is directed against the Peripatetics, who admit that Fire and the supreme region of the Air are moved perpetually by the concave of the Lunar heaven, through the force of the carrying-off of the primum Mobile — but per accidens, and not indeed against the nature of these elements, though still beyond nature [praeter naturam]; whereas straight motion upward from the centre is natural to them, as downward motion, or motion to the centre, is natural to Water and Earth. On these premises the Copernicans contend that circular motion should rather have been called natural, and per se, to these elements, and rectilinear motion preternatural and belonging to them per accidens; and so that perpetual

circular motion is naturally owed to the Earth as well. [Margin: Copernicus's doctrine of the motion of heavy and light bodies.] This was certainly the mind of Copernicus in Book 1, chapter 8, where he argues most speciously as follows: *Therefore what they say, that a simple body has a simple motion, is verified above all of circular motion, as long as the simple body remains in its natural place and in its unity. For in its place there is no motion other than circular, which remains wholly within itself, like a body at rest. Straight motion, however, comes upon things that wander from their natural place, or are thrust out of it, or are outside it in any way whatever. But nothing is so repugnant to the ordering of the whole and to the form of the world as for a thing to be outside its place. Straight motion, therefore, occurs only to things that are not rightly disposed, and are not perfect according to nature, while they are separated from their whole and desert its unity. Moreover, things carried upward and downward, even apart from circular motion, do not make a simple, uniform and equal motion; for they cannot be regulated by their lightness or by the impetus of their weight. And whatever falls, making a slow motion at the beginning, increases its speed as it falls; whereas, conversely, we see this earthly fire (for we see no other) languish at once when carried on high, as though the cause were acknowledged to be violence done to the matter. Circular motion, however, always revolves equally, for it has an unfailing cause; but the other has a cause that hastens to cease, through which, once bodies have reached their place, they cease to be heavy or light, and that motion ceases. Since, then, circular motion belongs to wholes, but straight motion also to parts, we can say that circular motion remains with straight, as an animal does with sickness. Indeed, Aristotle's dividing simple motion into three kinds — from the centre, to the centre, and about the centre — will be thought an act of reason only; just as we distinguish line, point and surface, although one cannot subsist without another, and none of them without body.*

[Margin: Galileo's propositions, full of various novelty.] XII. From this reasoning *Galileo* — but on the supposition of Aristotle's view, not his own, about the circular motion of Fire under the concave of the Moon — tries to teach, in Dialogue 2 on the System of the World, page 9 of the Latin, that straight motion cannot exist in a well-ordered World, but only circular, and that straight motion is of itself infinite, because a straight line is of itself indeterminate and infinite; and that straight motion perhaps existed in the first Chaos. He adds, however, that straight motion was instituted for bringing disordered bodies into order, and he brings in the authority of Plato, who thought that the bodies of the world were moved at first with straight motion and afterwards with circular, once they had acquired a certain degree of speed through straight motion. On page 17 he affirms that circular motion, and its determinate speed, cannot be acquired naturally, or without a miracle, without a preceding straight motion, but that once acquired it is from then on perpetual and uniform. On page 18 he says that straight motion cannot naturally be perpetual, but was given only to restore natural bodies to their place if they have fallen out of it, whereas circular motion can of itself be continued perpetually and is finite, because any point of the circumference is a beginning and an end; and that

therefore only circular motion and rest are suited to the conservation of order. On page 19 he denies that it is evident that heavy bodies descending are moved with a straight motion. On page 28 he says that rest, rather than straight motion downward, should have been called natural to the terrestrial globe, and on page 29 that straight motion is attributed with better reason to the parts than to the whole element. In the same place he affirms that the Peripatetics wrongly assign to the elements of Air and Fire circular motion as preternatural and straight motion as natural, since these elements always have been and always will be moved with circular motion, whereas as wholes they have never been moved with straight motion, nor will they ever be so moved; and that the Peripatetics have forgotten their own axiom that nothing violent is perpetual, and that the motion which is perpetual should rather have been called natural, and straight motion preternatural.

[Margin: The weakness of the Copernican and Galileist discourse against the Peripatetics.] XIII. And yet in the discourse of neither Copernicus nor Galileo do I see anything solidly put forward, either for themselves or against Aristotle, but only either an itch to pluck at Aristotle, or a beggary of very flimsy little reasons, scarcely consistent with themselves, scraped together for the diurnal motion of the Earth. For Aristotle does not affirm that a simple motion from the centre or to the centre — that is, straight motion — belongs to the Elements absolutely, and when motion is compared with rest; for absolutely he attributes to them, per se, rest in their natural place. But if they, as wholes or in their parts, are removed from it, he says that they have from the generator — that is, from their very birth — an intrinsic force of moving themselves with a simple motion, but the shortest possible, and so along a straight line to their natural place. Therefore, if Aristotle admitted that the World was made in time and that the elements were at first confused in Chaos, he would certainly assert that they afterwards acquired their place by straight motion; and that, if the whole Earth were placed outside its place, in the sphere of Fire, and the Fire in the middle of the elementary sphere, the Earth would descend to the place where it now is and the Fire would fly upward. Of this motion he had very probable, if not evident, arguments from the motion of the parts of Earth and Fire, which he supposed to move in this way on the testimony of the senses and by common consent. That the higher portion of the Fire and of the Air is carried off by the motion of the primum Mobile is not violent for them, since they are not on that account removed from their place; it is only beyond nature, and therefore it is not against that Peripatetic axiom, *Nothing violent is perpetual*. Now, granted that hypothesis — namely that they are removed from their place — it is natural for the elements to return to their place by the shortest and most determinate way, which is their distance from their natural place, rather than by a longer way; and the shortest is the straight line perpendicular to the earth, whereas that curvilinear line — mixed of straight and curved and fused into one — which the Copernicans are forced to admit in such a descent or ascent, is longer. Moreover, granted that same hypothesis, it is better for

the elements and their parts to be moved unequally, always accelerating their motion towards their native place, than with a uniform and equal motion: whether this happens because they are borne magnetically from one side and drawn from the other, and the more strongly the nearer they are; or because the impetus once impressed by heaviness or lightness ought not to be destroyed by a new impetus, while at every instant of time in which they are not in their natural place they have the force of producing in themselves impetus of a determinate degree, which, added to the earlier one or ones, makes the motion faster and faster towards the end. [Margin: Why does the motion of heavy and light bodies become faster?] Therefore, since an infinite impetus could not, or ought not, be given to them from the beginning — for it would have been in vain, if they were to be removed from their natural place only by a finite space, and that mostly a very short one — and yet so that they should not return slowly to their place, it was better that that speed should be finite but capable of increase to infinity [auctilis], that is, always growing until they reached the term of their natural rest. That straight line, then, is not infinite, but is determined here and now by whatever removes the parts of the elements from their natural place; nor does the inequality, difformly uni- formly increasing, stand in the way of the naturalness of such a motion; rather, it is most congruent with it. Nor does such a motion, in order to be natural, require perpetuity absolutely, but only in the way in which it is natural — namely conditionally, or on the hypothesis that the bodies must tend to their natural place, in which they are not; and if this hypothesis were in fact perpetual, the second act of that motion would also in fact be perpetual on either hypothesis. So much, then, for Aristotle, whose reasoning, though not set out by him as explicitly as by us, is far more solid, and more in conformity with the experience of the senses, on which physical science ought to build its reasonings.

[Margin: The arguments of Copernicus and Galileo [?] the motion of the Earth, very flimsy and inconsistent.] XIV. That the reasons of Copernicus and Galileo for the diurnal revolution of the Earth, begged from the comparison of rectilinear with circular motion, are flimsy and weak, and in places scarcely consistent with themselves, I show as follows. Copernicus prefers circular motion to straight for the reason that *circular motion remains wholly within itself, like a body at rest* — that is, because the whole movable body is not carried by its force to another place adequately distinct from the first. Therefore, when he carries the Earth round annually, this perfection is really taken away from circular motion, granted that it is not taken away formally by the force of the diurnal rotation. Next, if circular motion is more perfect because it is like rest, and is on that account owed to the Earth, then rest itself in its own place is more perfect, and consequently it is rest, rather than any motion, that is owed to the Earth. And so no sane Philosopher or Theologian would dare to ascribe to God a circular motion of rotation within himself, or within his own immensity: because local motion itself, even if it is not translational, when compared with rest and immobility, not only includes a change repugnant to God, but also

involves a perfection that is not simply simple; and absolutely it is better not to be moved, or better to rest, than to be moved and not to rest. Again, straight motion, as being enclosed in fact within two distinct termini that bound a finite interval, is finite, whereas circular motion is rather like the infinite, because it always begins to be repeated from the very point where it seemed about to end, since there is no greater reason from the nature of the circle why it should end at one point rather than another. Moreover, if straight motion is not natural to elements placed outside their place, because it is unequal and difform in speed, and therefore not simple, much less natural to them is a motion compounded of straight and circular, such as Copernicus attributes to them in their descent to their natural place; for besides the inequality it has in the space acquired in equal times, it also has an inequality of figure, which it is forced continually to change, approaching the circular or receding from it, always with a different course. For a straight line is much simpler than a parabolic or hyperbolic line, or any curvilinear line that is not circular — to say nothing of the length of this curvilinear path. Furthermore, when circular motion is said to be equal, this is already supposed gratuitously; for of itself it can be as unequal as rectilinear motion is. But Galileo too invents many such things for himself, of which kind are these: that circular motion, or its determinate speed, cannot be acquired naturally, or without a miracle, except through a preceding difform straight motion, but that once acquired it is perpetual and uniform. These are not only gratuitous but hardly coherent; for the means must fit the end and the end the means, but straight motion certainly does not fit circular motion, nor does difform motion fit uniform. Nor, when we spin a top, do we impress circular motion on it by means of straight motion, but by means of a circular rotation made with the cord; nor, conversely, when we impress straight motion on a stone with a sling, do we beg that straightness from circular motion: rather, we whirl the sling round so as to impress one impetus after another on the stone, which we afterwards convert into straight motion by means of a straight projection. Now, circular motion is said to be finite, and yet perpetual; but by the very fact that it is perpetual it is of itself infinite in duration. Nor is it terminated because any point can be taken as a beginning or an end; rather, by the very fact that none of them is determinately an end rather than a beginning, it has a certain indetermination, on account of which the circle is usually a symbol rather of infinity. The same Galileo, moreover, carps at Aristotle because he attributes per se to the elements straight motion, which as wholes they have never had, and says that circular motion, which fire and air always have, is per accidens. Let Aristotle, then, rebuke Galileo because he attributes per se to the Earth and Water a circular motion which they have never had, and says that straight motion — which, on Plato's view as adopted by Galileo, they had from the beginning — is intended by nature per accidens or secondarily. For he ought not to suppose what he is certain Aristotle will deny him, namely that the Earth is moved, or was at some time moved, circularly. But it is now tiresome to chase these flies, troublesome

though they are; and it is better to resolve the argument they are labouring at, once it has been compressed into form. It can, then, be formed thus.

[Margin: The 3rd Argument: its kernel, or form.] XV. *If Aristotle attributes to Fire and Air a diurnal circular motion, and that motion is more natural to them than straight motion, he must also concede to the Earth and Water a diurnal circular motion, as more natural to them than straight motion. But Aristotle attributes to Fire and Air a diurnal circular motion, and that motion is more natural to them than straight motion. Therefore Aristotle must concede to the Earth and Water a diurnal circular motion, as more natural to them than straight motion.* The MAJOR premise is plain from the parity of the elements, which Aristotle too acknowledges in this respect, that they agree in sharing a simple motion of the same kind, namely rectilinear. The former part of the MINOR is known from Aristotle; the latter part is proved as follows. That motion is more natural which is perpetual, uniform and simple, than one which either never was nor will be, or is not perpetual, nor uniform, nor simple. But the circular and diurnal motion of Fire and Air is perpetual, uniform and simple; whereas the straight motion either never was nor will be, if we are speaking of the whole element, or is not perpetual nor uniform, since towards the end it becomes faster and faster. Therefore, etc.

[Margin: 1st Reply, and the principal one.] It is replied, primarily, by conceding the Major of the first syllogism and the former part of the Minor, and denying the latter part of the Minor. To its confirmation the reply is: conceding its major if that motion is perpetual from an intrinsic principle, and the straight motion from an extrinsic one; denying it if the perpetual motion is from an extrinsic principle, and the straight motion, though not perpetual, is nevertheless from an intrinsic principle.

[Margin: 2nd Reply.] It is replied, secondarily, by Denying the Major and its proof drawn from parity. For even if it were natural for Fire to be moved circularly westward, and that from an intrinsic principle, so as to imitate the motion of the primum mobile, yet for the Earth, and for the Water enclosed in the Earth, this ought not to be natural; rest ought rather to be natural to them, so that the living creatures dwelling on them might experience in succession the alternations of risings and settings which they do in fact experience. Otherwise, if they were moved westward with the same motion, the creatures would not experience them, nor would the Phenomena be saved. In such a case, however, it would suffice that the four elements should agree in this: that if they were removed from their place, they would have a force of tending to it by straight motion. It is truly surprising that Galileo should wish to draw the Earth's circular motion out of the circular motion of Fire and Air asserted by Aristotle, and yet a contrary motion, namely eastward; for it ought rather to have been westward.

IV. Argumentum ab ingenti Magnitudine Octauæ ſphæræ & à ratione Totius collata cum Exilitate Telluris,tanquam particulæ Vniuerſi.

4th Argument, from the enormous Size of the Eighth sphere, and from the proportion [ratio] of the Whole compared with the Smallness of the Earth, as a tiny particle of the Universe.

XVI. We saw that this fourth argument was included in the second; but we thought it should be brought out separately and contested on its own, especially since the Copernicans try to arm it with certain specious similes. For Galileo, in Dialogue 2 on the system of the world, page 81 of the Latin, having said in the person of Salviati: *If we consider only the immense bulk of the Starry sphere in comparison with the smallness of the terrestrial globe, which is smaller by so many thousands of myriads, and consider besides the speed of the motion which the entire revolution must complete in the space of one day and night, I cannot persuade myself that anyone can be found to whom it would seem more reasonable and credible that this circumgyration falls to the celestial sphere and that the terrestrial globe stands unmoved* — at once brings in Sagredo, conceding that, if all else were equal on both hypotheses, it is more improbable to deny the diurnal motion to the Earth, and to the heaven ascribe it to the heaven, and that whoever does so is *not a little more absurd than a man who, climbing to the top of his watch-tower for no other purpose than to view the city and the surrounding countryside, should ask that the whole region be turned round for him, so that he need not undergo the labour of turning his head.* [Margin: Galileo's simile for this argument.] Kepler, however, preferred to come down from the watch-tower to the kitchen, so as to draw from there a simile suited to his palate. For in Book 1 of the *Epitome of Copernican Astronomy*, page 127, he writes: *But it is quite absurd that so great a mass* — he is speaking of the whole machine of the heaven — *which the Philosophers even contend is more perfect than the globe of the Earth, should travel so long a journey in going round, on account of the shape of this very narrow little ball (which is why the whole of it cannot enjoy the fire of the Sun at one time), when the Earth could relieve the heaven of this burden by a most economical turning of its own little body. For it would be just as if an inept cook, disdaining to turn the meat fixed on the spit, were instead to carry the fire round the meat in a circle.* [Margin: Kepler's simile.] For elsewhere he had said that the Earth roasts itself about its axis like a spit, by turning itself towards the Sun.

[Margin: Gassendi's similes.] Far more elegantly and urbanely, to be sure, Pierre Gassendi — not himself, indeed, absolutely a Copernican, but still taking on their persona, and inclined towards that Sect, were it not that the decrees of the sacred congregation stand in the way — argues as follows in Letter 2, *De motu impresso*, page 108: *Since reason persuades us that it is more likely that the ship moves towards the port than that the port and the ships, the houses and the adjacent lands move towards the ship itself; and, when someone views from a lofty tower the whole city set round about it, that it is more probable that the man has come up to the top of the tower and turns himself round in every direction than that the whole city sinks down and is turned round him; and, when an orator is delivering his*

peroration from the platform, that it is more fitting for his face to be directed in order to all the parts of the auditorium round about than for the whole auditorium to be turned round his motionless face — and similar things of that kind — *why, with the same reason persuading us, should it not become more likely, more probable and more fitting that the Earth moves towards the East and salutes in order the whole machine of the world and all the stars, than that so great a machine, and so many and such great stars, go round the Earth and salute it? Surely the ship is some sensible portion, or rather is of some magnitude, with respect to the port and the whole opposite shore; the man with respect to the city; the face with respect to the auditorium. But the Earth, compared with the amplitude of that so great machine, is not merely a point, but even, if anything more insensible can be imagined, something less than a point.* And so these men play the rhetorician. To this Lansbergen adds, in the *Progymnasmata astronomiae restitutae*, the character [ratio] of the Whole, saying that it is absurd that the Whole — namely the world, or the heaven — should be moved, and the part — namely the Earth — should rest. From this, then, there arises the following argument.

[Margin: The argument [?] in form.] XVII. *If, of two movable bodies, or bodies to be moved, one or the other must be moved in relation to the other, it is absurd that the one which is incomparably greater, and has the character of a whole, should be moved rather than the one which is incomparably smaller and has the character of a particle. But the whole heaven is incomparably greater than the Earth and has the character of a whole, while the Earth is like a particle. Therefore it is absurd that the whole Heaven should be moved rather than the Earth.*

[Margin: ıst Reply.] It is replied, first, by Conceding the Major if what is greater in quantity of mass is also greater than the other in quantity of power [virtus], or in perfection of substance and of its other properties; and by denying it if it is not greater in this second way, but smaller. And so the Minor proposition is conceded in the former sense and denied in the latter. For — I do not say the whole Earth with its inhabitants, but — a single man is incomparably greater than the whole machine of the heaven, setting apart the Intelligences, which are not parts of the heaven, nor forms of the celestial bodies. Nor, indeed, should one take here the bare globe of the Earth, without living creatures and without a creature that contemplates the divine works; for in that case perhaps neither the heaven nor the Earth would be moved — for what good, or to what end? We, therefore — unless we begrudge ourselves our own happiness, granted by the bounty of the Creator — we, I say, are those spectators for whom, as they sit in the theatre, that vast stage, lit with so many lights and revolving with its machines, displays its dances and catastrophes to be contemplated in turn. We are those kings and princes to whom the whole host of heaven — and, to borrow the words of the divine book, "that vessel of the camps on high" — repeating its review [lustrum] and running its rounds as if for a census, returns to be numbered. Unless perhaps we think it unworthy that God should have undertaken such great things for the sake of men, for whose instruction and redemption he expended even the Angels and — what is

inestimably greater — his only-begotten Son. As for the character of Whole and part, it is denied that the heaven, with respect to the Earth, has the character of a whole; for it is a co-part [compars], greater indeed than its fellow part in mass, but smaller in power. But someone could take the Intelligences together with the heaven — to which, as its movers, we conceded this motion in Section 2, chapter 1, numbers 4 and 9, in such a way that they go round together with it — and then the argument already mentioned would seem to have greater force, since in that way the heaven is greater than the Earth not only in mass but in power as well; although in reality the Intelligences are not an intrinsic part of the heaven, as the soul is of living creatures. For that reason a reply is given in another way.

[Margin: 2nd Reply.] It is replied, secondly, by Conceding the Major if what is greater is moved for the sake of the smaller as its ultimate end, and precisely in order to serve the smaller; but by denying it if it does not stop there, but orders its motion, or has it ordered, to its own nobler end, and so as to serve a worthier being, such as God, Best and Greatest. That the Intelligences, while they move the celestial bodies, move themselves — namely, to manifest His perfections and glory — need not be shown in this place, but is to be supposed as certain from sound Philosophy, let alone from Christian Theology.

[Margin: 3rd Reply, and retortion of the argument.] It is replied, thirdly, by Retorting the argument in part, in two ways. For if it is absurd that the heaven be moved for the sake of the Earth because it is of greater mass than the Earth, it would also be absurd that it be moved with any motion at all, let alone the diurnal one; and so the superior Planets would not be moved with their own motions either. For it cannot be said that they are moved per se about the Sun and per accidens about the Earth, since it is the Earth, not the Sun, that they perfect — or at least uncertain and disputed claims are being forced upon us. Likewise it would be absurd for the Earth to be moved with a diurnal motion for the sake of men, so as to offer them in succession the spectacles of the heaven to enjoy, since the whole Earth is of far greater mass than all men taken together.

V. Argumentum à Facilitate motus, ex Magnitudine Mobilis orta.

5th Argument, from the Ease of motion, arising from the Size of the Movable body.

XVIII. This is an offshoot no more fortunate than the preceding argument, from which it sprouted. Granted, say the Copernicans, that it is not absurd for what is greater to be moved for the sake of what is smaller; Nature nevertheless usually does what is easier, or less laborious and of less expense. But by the very fact that the Earth is of the smallest mass compared with the eighth sphere, let alone with the whole heaven, it is also easier to impart motion to it; and if motion is not exercised without some impressed quality, it is certainly of less expense to impress the impetus of rotation on this little sphere than on the most vast sphere of the Firmament. Let this argument too now be constructed according to the rule of the syllogism. *God and nature do what is easier and of*

less expense. But it is easier and of less expense to move the globe of the Earth with the diurnal rotation than the Machine of the Heaven. Therefore, etc.

[Margin: Syllogistic form of the argument, and 1st Reply.] It is replied, first, by Conceding the Major if other things are equal, and the same end that God and Nature intend can be obtained equally well; but by denying it otherwise. For God's purpose was to show the greatness of His Wisdom and Omnipotence: on the one hand by balancing the Earth immobile upon nothing — that is, upon its own centre — and upon air so fluid; on the other by joining so many motions, though contrary in appearance, in a single motion of the heaven or of the Planets, and in this way providing for living creatures, and especially for man. Nor can it be demonstrated by natural reason that this was not His end; and this end could not be obtained by moving the Earth. Granted, however, that by joining several motions in the single motion of the Earth He would also have shown great wisdom; still, as long as it is not certain, or more probable, that this rather than that was His purpose, we cannot conclude with certainty, or more probably, that He had regard to greater ease or to less expense. And indeed, if we follow our own estimation, weighing nothing but number or mass, it would have been of less expense to conserve the same light, once it had been produced in the air and the aether, than to produce new light over again at every moment; and less laborious to set the Planets going with a single and most simple motion, at once comprehensible in round numbers; to light the night with fewer fixed stars, and to guide sailors and farmers by fewer stars; to build the heaven and the Earth with less mass; and to create fewer species of plants, crops and animals. But God does not always look to what seems easier to us, but to what is better according to the end He has prescribed to Himself and to lower Nature.

[Margin: 2nd Reply.] One could reply, secondly, by Denying the minor proposition. For mass does not make its own motion more difficult insofar as it is mass, or precisely on account of its greater size, but only by reason of weight or of some similar quality; and I add that not even this holds absolutely, but only comparatively, with respect to the motive force, as also to the medium through which the body has to be moved. But neither for God nor for the intelligences can the machine of the heaven, under any of these heads, be more difficult to move than the Earth.

VI. Argumentum ab Infinitate Mundi Cæliq. ſupremi, vbi obiter quædam de Mundi Infinitate.

6th Argument, from the Infinity of the World and of the supreme Heaven, where, in passing, some things on the Infinity of the World.

XIX. Before we turn our arms elsewhere, away from the arguments drawn from Magnitude, which have been conquered and led in triumph, or at least invincibly repelled, we must dispose of the argument drawn from the Infinitude of the World. [Margin: Copernicus's discourse on the Infinity of the heaven.] Copernicus already touched on it in Book 1, chapter 8, arguing thus: *But*

according to that axiom of Physics, That which is infinite cannot be traversed, nor moved in any way, the heaven will necessarily stand still. But they say that outside the heaven there is no body, no place, no void, and absolutely nothing, and that therefore there is nowhere for the heaven to go out to. In that case it is surely a wonder if something can be held in by nothing. But if the heaven is infinite, and finite only at its inner concavity, it will perhaps be verified all the more that there is nothing outside the heaven, since everything, whatever size it occupies, will be within it; but the heaven will remain immobile. For the chief thing by which they strive to establish that the world is finite is motion. To these words he at once subjoins the conclusion that we recited above, but which must be repeated here: *Whether, then, the world is finite or infinite, let us leave to the disputation of the natural philosophers [Physiologi], holding this as certain: that the Earth, enclosed by its poles, is bounded by a globular surface. Why, then, do we still hesitate to grant it mobility, congruent by nature with its form, rather than have the whole world slide round, whose limit is not known and cannot be known? And why do we not admit that the appearance of the daily revolution belongs to the heaven, and its truth to the Earth?* To this argument, moreover, in the part where it rests on the spherical figure of the Earth, a sufficient reply has been given, unless I am mistaken, at number 5. But in the part where it touches on the uncertainty of infinity in the heaven and the certainty of finiteness in the Earth, it must be blunted in this place — though only after we have first heard what the Physico-Mathematicians, and not merely the Physicists, teach about the infinity of the world or of the supreme heaven.

[Margin: The opinion of Democritus, Epicurus and Metrodorus.] XX. If we believe Plutarch, in Book 2 of *De placitis philosophorum*, chapter 1, Democritus, Epicurus and their disciple Metrodorus posited innumerable worlds in the infinite, ranging without measure through its whole extent. Seleucus posited an unbounded world; [Margin: Diogenes's.] Diogenes an infinite Universe, but a finite World, for he distinguished the world from the Universe. [Margin: The Stoics'.] So did the Stoics, who, as Plutarch adds in the same place, said that the Universe consists of the World and the void, and that this whole made up of both is infinite, but that the World is distinct from the void, and is one, and is bounded by a globular figure. [Margin: Aristotle's.] Aristotle, however, in Book 3 of the *Physics*, tries to overturn every actual infinite; in Book 7 of the *Physics*, text 78, he denies that a finite thing can move in an infinite time; and in Book 1 of *De caelo*, from text 33, he contends that the World is not infinite, as very many of the ancient philosophers, he says, believed. His chief argument is that it is impossible for an infinite body to be moved circularly, let alone in a finite time: otherwise there would be a proportion between a finite and an infinite line comprehended by similar arcs and under an equal angle, and an infinite space could be traversed in a finite time, namely 24 hours. Besides this there are other, more obscure arguments, which can be seen up to text 75. In that place, therefore, he supposes as certain what is now in question, namely that the heaven turns circularly. [Margin: Pythagoras's.] [Margin: Plato's.] But

before him, too, Plato and Pythagoras, as Laertius reports in their lives, asserted that the World is finite and of spherical figure. [Margin: Cleomedes's [?].] Cleomedes too, in Book 1 of the τῆς κυκλικῆς θεωρίας [Greek: tēs kyklikēs theōrias, "of the circular theory" — the title of his work], relying on Aristotle's reasons, establishes that the World is both globular and finite. [Margin: Pliny.] Pliny the Elder, however, in Book 2, chapters 1, 2 and 7, speaks of the World in such a way as to make it God and Nature, or to make God himself the soul and nature of this World; and therefore he does not clearly express whether it is finite or infinite. For in chapter 1 he says: *The World, and this which it has pleased us to call by another name the heaven, by whose encircling sweep all things are covered, it is right to believe to be a divinity, eternal, immense, neither begotten nor ever to perish. What lies outside it is no concern of men to investigate, nor can the conjecture of the human mind grasp it. It is sacred, eternal, immense, whole in the whole, nay rather itself the whole; finite, yet like the infinite; certain of all things, and like the uncertain.* And a little later, against those who had posited infinite and innumerable Worlds, he adds: *Or, if this infinity can be assigned to the nature of the maker of all things, would not that same thing be more easily understood in one, especially in so great a work?* And soon after: *It is madness, sheer madness, to go out of it and, as though everything within it were plainly known, to scrutinize what lies outside — as if, indeed, one who does not know his own measure could take the measure of anything, or the mind of man could see what the world itself does not contain.* For Pliny is prone, in order to hammer out some clever and sublime sentence, to speak impiously and audaciously even of God himself. Thus in this place he makes this God of his uncertain and semi-corporeal, ignorant of his own immensity and incapable of it — although of this God he says in chapter 7: *Whoever God is (if indeed he is another)* — that is, distinct from the world — *and in whatever part, he is wholly sense, wholly sight, wholly hearing, wholly soul [animae], wholly mind [animi], wholly himself.* Since, however, he attributes a spherical figure to the world and acknowledges that it turns in the space of 24 hours, he seems to acknowledge it as bounded and finite. [Margin: The excellence [?] of the spherical figure [?].] For he says in chapter 2: *That its form is rounded into the shape of a perfect orb is shown, first, by the name and the consensus of mortals, who call it an orb, and also by the evidence of things: not only because such a figure in all its parts converges upon itself, must sustain itself, and encloses and holds itself together, needing no joints and sensing no end or beginning in any of its parts; nor only because it is most apt for the motion with which, as will soon appear, it must continually turn; but also by the proof of the eyes, because it is seen as convex and central from whatever side one looks, whereas this could not happen in any other figure.* He would have done better to say "concave", for the convexity of the heaven cannot be seen by us. Finally, in chapter 3, he writes of its motion as follows: *That this form, then, is carried round in an eternal and unresting circuit, with unspeakable speed, in the space of twenty-four hours, the risings and settings of the Sun have left no doubt. Whether the sound of so great a mass, rotating in ceaseless*

whirling, is immense and therefore beyond the sense of the ears, I could not easily say. So he again calls the immensity and infinity of the World into doubt.

XXI. Let it be enough to have sampled thus far these few, but rather select, opinions of the Ancients concerning the infinity of the world. What the more recent Scholastics and Physicists have thought I have reported more fully in the Physical questions, and this is not the place to repeat that controversy with all its arguments for and against. It need only be recalled that there are four opinions on this matter. [Margin: The opinions of the more recent on the Infinity of the World.] Some deny that the World is actually infinite, either because they think that every infinite which is, as they call it, categorematic is ἀδύνατον [Greek: adynaton, "impossible"], or because there is no sufficient indication of this infinity, and entities are not to be multiplied or extended without necessity. Others concede that the World is Infinite, but deny that it is bounded by any figure, or mobile as a whole within itself, let alone outside itself. Others again admit that it is Infinite, and yet bounded by a spherical figure, but deny that it can be moved in a finite time; for with them it is not the same thing to be finite and to be bounded or figured. [Margin: The acceptation of the Infinite.] For the Infinite, they say, is predicated analogically, and its first analogate is that which has all the perfections signified by the name of infinite: namely, that it embraces within itself all things possible in its own genus, and lacks a limit on every side, taken both negatively and privatively — that is, so that nothing can be designated in it to which the negation of further extension immediately belongs, even if that further extension were said to be impossible, and therefore the negation of it, as not connoting an aptitude for the thing denied, would be a mere negation and not a privation. For from these perfections, they say, it follows that it is untraversable. But among the secondary analogates participating in infinity, they also admit that which, although it is bounded by some figure and does not comprehend within itself everything possible in that genus, is nevertheless so great as to be untraversable, and not measurable by any finite and determinate measure of the kind that can be taken among the smallest and replicated, so that however many measures of this kind are replicated, there always remains something further in it to be taken. Finally, some agree that the World can be called infinite and configured externally with a spherical surface, and nevertheless movable and capable of being turned round in the finite time of 24 hours, but by an infinite power producing an infinite impetus; and they hold that infinity of time in the motion does not necessarily follow from the infinity of the space traversed. Or at least, if the World above the planetary heaven is fluid, or not wholly and continuously solid, they hold that the part which contains the stars visible to us and the Planets, being finite, can be moved within 24 hours, while the remaining part stands immobile. Among those who admit the infinity of the World, this opinion seems less absurd and less difficult to understand.

XXII. It remains, therefore, as I promised a little earlier, for us to indicate what certain Astronomers or Physico-Mathematicians have thought about

the infinity of the World and of the heaven. And indeed, of Copernicus's ambiguous opinion we have learned enough from himself, and also that, so far as it lies with him, the infinity of the World, if it were admitted, or even an infinite distance of the Fixed stars, would not hinder his hypothesis of the annual translation of the Earth at all, but would rather greatly help it. [Margin: William Gilbert's opinion on the Infinity of the World.] Moreover, William Gilbert, in Book 6 of *De magnete*, chapter 3, calls the sphere of the Fixed stars Immobile, and thinks that if the primum mobile were in it or above it, it would be infinite; and so he adds: *But of an infinity and of an infinite body there can be no motion, and therefore no diurnal motion of that most vast primum Mobile.* For this reason, on account of this argument among others, he concludes that the diurnal revolution belongs to the Earth rather than to the supreme heaven. [Margin: Marsilius Ficinus's opinion.] On the contrary, Marsilius Ficinus, on Plotinus's book *De caelo*, chapter 3, teaches that the World is not infinite: either because it would lack order and figure; or because, if it were imagined to be moved circularly, there would be slowness towards the centre and infinite speed from the centre upwards — for the parts nearer the centre, designable finitely to infinity, would be slower and slower, but those from the centre upwards faster and faster; and so on the one side there would be no motion of it at all, on account of the infinite slowness, while on the other it would take place in an instant, on account of the infinite speed; or else infinite slowness and speed would combine into a state, that is, rest. Or else because, since there would be an immense space between any lines drawn out from the centre, the effort of the mover would be in vain, and consequently there would be no motion. [Margin: Descartes's view.] Descartes, however, in the *Principles of Philosophy*, Part 1, from number 25 to 27, declares that we ought not to weary ourselves with disputations about the infinite, since, as we are finite, it seems absurd to him that we should try to determine anything about it, and so, as it were, to limit and comprehend it. All those things, however, to which no definite limit can be assigned beyond which God could not make more, or greater, or better things, he calls not Infinite but Indefinite; and he adds: *And these we shall call indefinite rather than infinite: both so that we may reserve the name of infinite for God alone, because in him alone, in every respect, we not only acknowledge no limits, but also understand positively that there are none; and also because we do not in the same way understand positively that other things lack limits in some respect, but only negatively confess that their limits, if they have any, cannot be found by us.* [Margin: Giordano Bruno's opinion. And Galileo's.] On the contrary, Giordano Bruno of Nola, in the book *De maximo et immenso* and in the book *De infinito et innumerabilibus*, does not hesitate to assert that this World is infinite upwards. Galileo, however, in Dialogue 3 on the system of the World, page 239 of the Latin, calls into doubt whether the World is finite, figured and has a centre, or is rather infinite, unbounded, and lacking a centre and circumference; and he says that Aristotle's reasons, which ultimately rest on the mobility of the diurnal motion, are as uncertain as the motion that Aristotle

assumed and attributed to the heaven rather than to the earth. Granted, he concedes for the time being to Simplicio — with whom he brings in Salviati disputing — for the sake of argument, that the World is finite and spherical and has a centre, so that, even with this liberally allowed, he may show that it does not follow that the Earth is at the centre of the universe, or that heavy bodies tending to the centre of the earth tend to the centre of the Universe. [Margin: Kepler's.] Among the Copernicans, however, Kepler — both in the book *De stella nova*, on the new star seen in Serpentarius, chapter 17, and in the *Epitome of Copernican Astronomy*, Book 1, page 39 — denies that any of the visible stars is distant from us by an actually infinite interval. For, he says, to be infinite and to be bounded are mutually repugnant; and likewise to be infinite and to have a finite proportion to another infinite. Both of these inconveniences would follow if some visible star were distant from us by an infinite interval; for the apparent diameter of the star would be increased by an infinite increment, as would the distance of the lines under whose angle it would be seen; and yet, so increased, it would still be enclosed within the termini, or points, bounding the diameter, and under a definite visual angle. Moreover, in the same place he denies that, even if some stars were not visible because of their huge distance, the space upwards is infinite, because their number would be finite, and from things finite in magnitude and number an infinite cannot be compounded. Some things in this discourse would need the file, if this were the place to range at large over this controversy. On it I wished only to indicate the bare opinions, so that it might be clear that, although among the Copernicans and some others there has been some suspicion of the infinity of the World, yet it has not been among all of them, let alone among everyone; and by what arguments, chiefly, its infinity is usually attacked. To these add the conjecture about finiteness taken from the Refractions of the Fixed stars, which I set out in Book 6, chapter 7, in the last Scholium. Now to the argument contained in Copernicus's words, which we form as follows.

[Margin: The 6th Argument reduced to form.] XXIII. *If the motion of diurnal revolution must be attributed to one or the other of the bodies — namely either the supreme heaven or the Earth — it must be attributed rather to the one that is certainly established to be movable than to the one that is not movable, or of which it is not certainly established whether it is movable or not. But it is certainly established that the Earth is movable, whereas the supreme heaven either is not movable, or it is not certainly established whether it is movable. Therefore, etc.* [Margin: Proof of the Major.] The MAJOR premise seems most certain. For although what we are speaking of could not have been uncertain to God, who imparted this motion to one or the other, yet for us, to whom it is not certain, prudence dictates — so that we do not expose ourselves to the danger of erring — that we ascribe the motion to the body to which we are certain it is not repugnant, rather than to the one whose repugnance to it we may legitimately suspect. [Margin: Proof of the Minor.] The MINOR premise, too, is already certain as regards the Earth, from its figure and its finite measure, found by Geometrical method, according

to what was said in Book 2, chapter 7. As regards the supreme heaven, however, it has not yet been demonstrated by anyone that it is not infinite; and if it is infinite, it is not certain that it is movable; or, if this has been demonstrated, it has been demonstrated by no other argument than from the diurnal motion, which is here called into controversy.

[Margin: Reply to the 6th Argument.] One can reply by Denying the Minor, if by the name of the supreme heaven is understood either the Firmament, or at least the aggregate of the visible Fixed stars. For it is physically evident to us that they are moved with the diurnal revolution, and therefore we are certain of their mobility from the motion itself, since Copernicus himself and the Copernicans admit that the appearance of this motion is in the heaven, if we will abide by sense — just as it is evident, in dependence on sensible experiments, that the Earth is of finite measure. Granted that for the evidence of the former a simple experiment suffices — by which we see the Fixed stars rise above the Horizon and roll down to the West, and after 24 hours return to the East, and traverse in a finite time arcs similar and proportional to arcs of the terrestrial circumference — whereas to measure the Earth and determine its figure more is needed. But if the Copernicans say that only one of these two is evident to us disjunctively, namely that either the Fixed stars or the Earth move, I say that this disjunctive is evident Mathematically, or even Metaphysically, supposing (as indeed our opponents suppose) that the local variation appearing between the stars and us takes place through local motion, and not through illusions of the eyes, or the reproduction of bodies, etc. But it does not follow from this that the other part is not physically evident, and the burden of proof lies on the one who denies it. I say nothing, meanwhile, of Sacred authority, for at present we are examining bare reasons. What happens, however, with the part of the heaven above the Fixed stars — whether it is moved and is finite, or is infinite and immobile — has nothing to do with this argument.

It is replied, secondly, by conceding the Major if other things are equal, and denying it if they are unequal, as in fact they are. For many other considerations are given that outweigh this comparison of certainty regarding the finite circumference of the Fixed stars and of the Earth, on account of which the diurnal motion is to be attributed rather to the Earth.

VII. Argumentum à ratione Loci & Continentis deductum.

7th Argument, drawn from the nature of Place and of the Container.

XXIV. Copernicus has not yet ceased to press the Earth's rest towards motion. For he says in Book 1, chapter 5: *Since the heaven is what contains and covers all things, the common place of all things, it is not at once apparent why motion should not be attributed rather to the contained than to the container, to the located rather than to the locating.* And again in chapter 8: *I add also that it would seem quite absurd for motion to be ascribed to the container or locating thing, and not rather to the contained and located, which is the earth.* This reasoning seems to have greater force against the Peripatetics with their Aristotle, who in Book 4 of the *Physics*, chapter 5,

text 42, define place as *the first immobile boundary of the containing body*, and who concede to the heaven the character [rationem] of universal place. [Margin: Form of the 7th Argument.] One may therefore argue thus: *Local motion is to be ascribed to the located rather than to the place, since place requires immobility; but the Heaven is the place with respect to the Earth, and the Earth the located. Therefore motion is to be ascribed to the Earth rather than to the heaven.*

[Margin: 1st Reply.] The Peripatetics would reply, from the same text 42 of the fourth book of the *Physics*, on the doctrine handed down by Aristotle from text 35, by distinguishing the major premise. They would concede it if it is understood either of a motion by which the whole place is carried, together with the located, to another place — for in that way the place would lose the character of place and take on the character of a vessel — or at least of a motion by which, in carrying off the located, the place ceases to surround it; and if it is understood of the immediate place. They would deny it if the proposition is understood of any local motion whatever, or of the remote place. The supreme Heaven, however, is not carried as a whole to another place, but remains in the same place as regards its whole being; or, if it is not strictly in a place, because it has no other body outside it by which it is contained, it is not carried to another place either. Much less does it leave the Earth outside itself, as the parts of a river leave the fish behind, even when they are at rest; rather it behaves like air stirred about a Tower, which does not on that account cease to be the place of the Tower. Nor is the supreme heaven the immediate or first surface containing the earth.

[Margin: 2nd Reply.] Someone might, secondly, reply by turning the argument back against the motion of the earth asserted by Copernicus. For the Earth too, together with the neighbouring air, is the place of plants and animals; therefore either it ought not to be moved, or, if it suffices for its mobility that it does not leave behind the things located in it, this suffices much more for the heaven, which neither leaves behind the things located in it nor carries them elsewhere with it like a vessel — as happens in the hypothesis of Copernicus, who adds an annual motion of translation of the earth as well. So for him the Earth turns out to be a vessel rather than a place.

VIII. Argumentum ab Incorruptibilitate Cæli deſumptum.

8th Argument, taken from the Incorruptibility of the Heaven.

XXV. Copernicus uses this argument in one way, Kepler, following Origanus, in another. [Margin: Copernicus's Argument.] The former argues thus in Book 1 of the *Revolutions*, chapter 8: *To these is added also that the condition of immobility is thought nobler and more divine than that of change and instability, which for this reason befits the earth rather than the world.* [Margin: Kepler's argument from Origanus.] But Kepler, in Book 1 of the *Epitome of Copernican Astronomy*, page 128, says that motion is of the genus of things that are not, but come to be; and that it therefore does not belong to those things that hold the degree of their perfection perpetually in themselves, but to those which, unless they

are moved, grow torpid with sloth and are corrupted — such as, in the Earths themselves, Water and Air, and many bodies living in these elements.

[Margin: Reply to Copernicus.] To Copernicus, however, the reply is that the heaven is not intrinsically incorruptible, as we said in Section 1, chapter 6, number 6; indeed Kepler admits that it is in fact capable of corruption. Next, if it is contended that it is incorruptible, then only that motion is repugnant or unbefitting to it which tends to corruption, and the diurnal revolution is certainly not of that kind: otherwise it ought long ago to have corrupted the whole Earth, to which he ascribes it. Further, this [?] motion is not incongruous even to the Intelligences themselves, let alone to the heaven or the stars. Finally, by this argument all motion would have had to be banished from the heavens; and so, since it proves too much, it proves nothing. [Margin: Reply to Kepler.] Kepler, for his part, will be abundantly answered if the Air is blown through by winds from time to time, and the Waters are preserved from putrefaction by the course of rivers and the ebb and flow of the Seas, besides the remedy of their saltiness; and since he does not fear corruption for the Earth, there is no reason for him to attribute motion to it on that account. If he grants that motion can belong to it on other grounds, let him grant also that it can belong to the heaven, even if the heaven does not need it for its own preservation. And finally, let him acknowledge, from this or from the motion of the Planets, that local motion was not instituted primarily of itself, or universally, to preserve from corruption by agitation and ventilation.

IX. Argumentum à Fluiditate Cæli, & Conſtanti Diſtantia Fixarum inter ſe.

9th Argument, from the Fluidity of the Heaven and the Constant Distance of the Fixed stars from one another.

XXVI. The Copernicans would perhaps[38] seem to have deserved very well of the heaven, being so solicitous for its integrity and health — especially those who, fearing for its fluid substance, or at any rate certainly feigning fear, thought that all motion was to be driven away from the bounds of the heaven, at least of the supreme heaven, lest either its substance or the stars themselves be scattered and flow apart through the great speed of the whirling. [Margin: Longomontanus's argument, supposing a fluid heaven.] Thus Longomontanus, who asserts not indeed the annual but nevertheless the diurnal motion of the Earth, confesses in Book 1 of the *Theorica*, towards the end of chapter 1, that he was confirmed by this argument too in transferring this motion to the Earth, when he says: *I add also that, since the fixed stars — which it would be reasonable to hold are removed at no equal distance from the centre or the earth, and hang in the most limpid heaven, and, like the globe of the earth, are balanced on their own centres with equal weights — have suffered no separation in their distances from one another since the founding of the world: who then, with such assertions, will attribute real motions to them, unless it be one who would stubbornly defend Sacred Scripture in a*

[38] printed *fotſitan*

few places, and in places which (as they seem) are accommodated to human capacity only in appearance? And in the same place, chapter 4, he repeats that among other things he was led to bring back both the diurnal motion and the motion of the precession of the Equinoxes from the heaven to the earth, *lest the stars fixed in the most limpid heaven be pulled apart from one another, if you presumed that each one was set going separately by some motion of conveyance: although perhaps this too might in some way be conceded in a celestial expansive stereoma* — that is, even if someone were to admit that solid heaven; for στερεάμα[39] [Greek: stereōma, "firmament"] signifies a solid structure [solidamentum], or a solid body.

[Margin: Gilbert's argumentation, supposing a fluid heaven.] XXVII. William Gilbert argues in a different way, from the liquid thinness of the Firmament, in Book 6 of *De magnete*, chapter 3. For he philosophizes thus: *Moreover, what craftsman ever discovered that the stars which we call fixed are in one and the same sphere, or established by reason that there are any real and, as it were, adamantine spheres? No one has ever demonstrated this very thing. Nor is there any doubt that, just as the planets stand off from the earth at unequal intervals, so those huge and most numerous lights are separated from the earth by various and most remote heights, and do not adhere to some spherical framework or firmament (as they imagine) and vaulted body. Thus the intervals of some are conceived by a kind of opinion rather than in reality, on account of their inscrutable distance; others far surpass them, and are by far the most remote; and since these are placed in the heaven at various distances, either in the thinnest aether, or in that most subtle fifth substance, or in a void, how will they remain in so great a whirling of a vast orb, a body most uncertain?* Therefore, since he holds that the non-wandering stars are in a fluid aether, and indeed separated from one another upwards and downwards at distances various beyond measure, he thinks it is to be feared that, if they were turned round with the motion of so vast a heaven, they would toss this way and that with a turbulent and many-wandering agitation, like planks in a shipwreck. And further on he again lays it down thus: *Not, therefore, are those confused crowds of stars carried or moved by the firmament, nor do they have their position from it; much less from the primum mobile; nor are they torn apart and disturbed by a contrary and most rapid impulse. Ptolemy of Alexandria seems to me too timid and faint-hearted, who shudders at the dissolution of this lower world if the earth were moved circularly. Why does he not fear the ruin, dissolution, disturbance and conflagration of the universe, and celestial and supercelestial calamities, from a motion beyond all thoughts, dreams, fables and poetic licences, insuperable, ineffable and incomprehensible? Therefore we are carried by the diurnal rotation of the earth — a motion, that is, more fitting; and as a skiff is moved upon the waters, so we, with the ear-* th are turned round, and yet we seem to ourselves to stand still and be at rest.* He also presses the argument from incredible speed, about which much more will have to be said separately in the following chapter.

[39]so printed, for στερέωμα

[Margin: Galileo's reasoning, supposing a fluid Heaven.] XXVIII. And this, to be sure, is the sixth confirmation of the diurnal rolling of the Earth, which Galileo counts in Dialogue 2 on the system of the world, page 85 of the Latin, when he says: *There is added an absurdity (and this is the sixth inconvenience) for those who discuss the matter soundly: that no thought can comprehend what the solidity of that most vast sphere must be, in whose depth so many stars are so tenaciously fixed that, without any variation of position among themselves, they are swept round in concord with so great a disparity of motions. Or if indeed the heaven is fluid, as it is more reasonable to believe, so that each star wanders through it by itself, by what law are their motions governed, and to what end does it come about that, seen from the earth, they appear as if made by one single sphere? It seems to me that, for obtaining this, it is a course as much easier and more convenient to make them immobile, not wandering, as it is readier to keep at one's beck a courtyard paved with stones than the crowd of children running about in it.*

[Margin: Gassendi's opinion on this.] Gassendi, however, although he does not state clearly enough whether he supposes the sphere of the Fixed stars solid or fluid, and makes no mention of a Crystalline heaven above it and below the primum mobile except as the opinion of others, nevertheless suggests, in Letter 2, *De motu impresso* etc., page 111, that a scattering of the stars by the diurnal rapidity is to be feared. *But how much*, he says, *do you think the absurdity that confronts us will be increased, once a point has been taken in the circuit of the primum mobile, especially with one or another crystalline heaven interposed? And let them object besides that the parts of the earth would be torn apart by that so great whirling: how much more will a tearing apart be to be feared for the parts of the primum mobile, snatched away as they are by an incomparably more rapid whirling?* But before we take this panic terror from their minds, let us bring the whole force of this argumentation to the rule of the syllogism, which in the end is as follows.

[Margin: Argument 9 in Form.] XXIX. *If the non-wandering Stars were moved with the motion of the Firmament, by the diurnal whirling, they would not keep perpetually the same distance from one another. But the non-wandering stars do keep perpetually the same distance from one another. Therefore the non-wandering stars are not moved by the diurnal whirling with the motion of the Firmament; it remains, therefore, that the Earth itself rather is moved with such a motion.* The MINOR premise is certain from what was said in Book 6, chapter 10. The MAJOR is proved, on the one hand, from the incredible speed of that whirling; on the other, from the fluidity of the Firmament, which is unfit to hold any fixed stars whatever always at the same distance from all the other stars; or else from its solidity, unless that solidity were supposed to be so great that human belief and estimation cannot reach it.

[Margin: Reply.] The reply is to deny the Major of the proposed syllogism, and its proof. For if the Firmament is supposed fluid, it is neither necessary nor congruous with the more probable reasoning that the non-wandering stars be moved with the motion of the Firmament; rather, they would more probably be supposed to be moved by Intelligences, either singly, or enclosed together

by some other bond, as it were a net, as we said in Section 1, chapter 7. For the chief reason for asserting a solid Firmament, after the authority of many Fathers and Doctors, is that very perpetuity of the equal distance of the Fixed stars, kept by those same stars and observed since the most ancient times of Astronomy. But if the Firmament is so solid that it neither rubs against another body apt to concur in kindling through the extrusion of hotter spirits or of latent little fires, nor strikes against another body, nor is forced by a sudden shock to stop or recoil, but is carried round with an even tenor of motion always within the same space, then it is feared in vain that it will break or burst apart, and so, its framework dissolved, disturb the intervals of the Fixed stars. Nor can Gassendi, of all people, reject this reply, since he replies in a similar way about the Earth in the same place, saying: *Although there is no danger for the parts of the Earth themselves, which, because they all cohere among themselves and are always carried with a natural and even motion, behave just as if they were at rest; and the only accident to be feared would be if the earth struck against a resisting body, or otherwise came to a sudden halt.* Could not GOD infuse into the Firmament as great a coherence and solidity as he put into the Earth, and much greater — even if that solidity had to be reckoned so great as to display an admirable work of God?

XXX. Therefore, if the Copernicans aim at this — to take from the divine works their wonderfulness, or to take from human minds either wonder at it or belief in it — they do not act consistently, since they press upon us the divine Omnipotence and Majesty of the Creator from the huge vastness of the interval between Saturn and the Fixed stars and from the immensity of that supreme heaven, as we shall see later; nor do they agree with the sayings of very many Wise men, and above all with those of the divine letters. [Margin: The glory of God shines out most of all in the Firmament and its motion.] For what else do those most celebrated verses of Psalm 18 proclaim, *The heavens tell the glory of God, and the Firmament announces the works of his hands*? How does it announce them, except chiefly by the harmony of the diurnal revolution, by which the alternating turns of days and nights, repeated by so constant a law ever since the founding of the world, rouse mortals with a kind of secret sound to the knowledge of God and the recognition of his power? For there follows: *Day pours out the word to day, and night shows knowledge to night*, and *Their sound has gone out into all the earth, and their words to the ends of the world.* What else, likewise, do those words of Ecclesiasticus, chapter 43, suggest to us: *A vessel of the camps on high, shining gloriously in the firmament of heaven*? Or what else does the Prophet Baruch signify in chapter 3, when, from the light of the stars rising in succession upon the world, he commends GOD with sublimity of speech, saying: *He who sends forth the light, and it goes; and he called it, and it obeys him with trembling. And the Stars gave light in their watches, and rejoiced; they were called and said, Here we are; and they shone with gladness for him who made them. This is our GOD, and no other shall be accounted against him.* What else, I say, do these passages intimate to us, but that it was and is as easy for our GOD

to direct the host of stars in order through the Intelligences at his nod, without any confusion of the place once assigned to them as their post, as it is for a most experienced Field-commander, or a most skilled Commander of an army, to move his forces in column, travelling however great and rapid marches, and to govern them through his centurions and tribunes, as if the camp, enclosed by its very rampart as by a kind of vessel, were being carried along? Finally, let us hear GOD himself questioning, in Job 38: *Will you be able to join the twinkling stars, the Pleiades, or can you scatter the circuit of Arcturus?* As if he said: Can you, or any manikin like you, bind together, in so tiny a space of the heaven as that which the asterism of the Pleiades occupies, so great a multitude of stars, with so perpetual and constant an order and an unchangeable constancy of intervals? (For the Telescope has revealed not seven only, but far more stars in that tract.) Or can it come about by your effort or anyone's that Arcturus, although it repeats its circuit every day in so ample a round and with such speed, should be scattered and otherwise thrust out, and forced to run off wandering along one path after another? By no means — truly, by no means.

X. Argumentum ab Indigentia Telluris & Independentia Stellarum à Terra, quæ non eſt finis, ad quem ordinata ſint ſidera.

10th Argument, from the Need of the Earth and the Independence of the Stars from the Earth, which is not the end to which the stars are ordered.

XXXI. This is the last of the arguments — of those, at least, that belong to this chapter. *It is ridiculous*, says Gilbert in Book 6 of *De magnete*, chapter 3, *that the Heaven should be moved for our sake, and for the sake of the earth, so small a globe.* For it seems unworthy of the majesty of the Heavens that they be moved with the diurnal motion for the Earth's benefit, when they themselves do not need that motion, while the Earth itself remains unmoved, which alone, or most of all, needs the good that follows from that motion. For whatever is moved locally is moved to this end: either to acquire some good which it never had — and thus animals are moved, which for this reason are called living things by the Philosopher, because they acquire for themselves something besides what they have from birth, and perfect themselves chiefly through motion, which plants accomplish without motion — or certainly it is moved to recover a lost good, or to restore itself to the place in which it can best be preserved; and in this way the bodies of the elements and of inanimate mixed bodies are moved. Lansbergen presses this argument in the *Progymnasmata*, adding that the earth is moved with less expenditure [?] than the stars, just as it is easier for a mother to bring her children up to the fire to warm them than to carry round the fire that warms them. Kepler too presses it, in Book 4 of the *Epitome of Copernican Astronomy*, page 500, saying: *The other argument destroys all motion whatever of the sphere of the Fixed stars* — indeed, I say, *of all the Planets. For it is not apparent to what good, since there is nothing outside from which or towards which that translation might vary both position and appearances; and it obtains by rest whatever it could acquire by any motion whatever. For it is from its rest that the motions of*

all bodies are understood, and unless it provided place — which it does most rightly by resting — nothing could be moved. The same author had said, moreover, in the *Dissertatio cum Nuncio sidereo*: *Let man therefore acknowledge that he is not the source and origin of the world's adornment, but depends on the true source and origin. Add this too, which I said in the Optics: that for the sake of contemplation — for which man was made, and adorned and equipped with eyes — man could not rest at the centre, but must travel round with an annual motion in this ship of the Earth, for the sake of surveying; just as surveyors of inaccessible things exchange one station for another, so as to obtain from the intervals between the stations a proper base for the surveying triangle.* For what he says here of the annual motion applies also, if it applies at all, to the diurnal. Let the argument now be gathered into a summary.

[Margin: Form of the 10th Argument.] XXXII. *Motion is to be attributed to that which needs that motion for its own good, and not to that which does not need it. But it is the Earth that needs the diurnal motion — indeed the annual too — for its own good, not the heaven. Therefore the diurnal motion, and indeed the annual too, is to be attributed to the Earth, and not to the heaven.*

The reply is to deny the Major if what is to be moved either is moved not from within but from outside, by something ordering it to the good of another; or if the movable, whether moved from within or from outside, is by its nature ordered to perfecting other things by means of that motion, so that its own good is to be perfective of others, while it meanwhile suffers no detriment itself — such are the heavens and the stars; and to concede it if none of these considerations applies [militet] in such a movable. As to what is added — that we are not the end to which the stars and the heavens and their motions are ordered — we deny that proposition. For we have already shown the opposite clearly enough in Section 2, chapter 4, number 10, as consonant with Sacred Scripture, let alone with the Fathers.

CAPVT VI.

Chapter 6.

Proponuntur & Diſſoluuntur Septem Argumenta ex conditionibus ipſius Motus Diurni, pro Telluris potiùs quàm Cæli Diurno motu.

Seven Arguments drawn from the conditions of the Diurnal Motion itself, for the Diurnal motion of the Earth rather than of the Heaven, are Proposed and Resolved.

I. The FIRST and chief argument of the Copernican sect — and, as the proverb says, its Achilles — is the one derived from the incredible speed of the Fixed stars, if they rather than the Earth were moved. To present this speed as incredible, various authors propose it according to the various distances of the Fixed stars from the Earth. [Margin: Mästlin's calculation for the speed of the Fixed stars.] For Mästlin, in his preface to Rheticus's *Narratio prima*,

first assumes from Reinhold, who computes the Ptolemaic dimensions of the orbs, a distance of the Fixed stars of 25,000 semidiameters of the earth; from this, he says, it follows that a fixed star placed on the Equator of the heaven is swept, in a single second of an hour — a little space of time in which you could scarcely utter three or four words in headlong speech — beyond fifteen hundred German miles. Next, assuming from Alphraganus [al-Farghānī] a distance of the Fixed stars from the earth of 20,110 semidiameters of the earth, and so a diameter of 40,220 terrestrial semidiameters, to each of which he assigns 860 German miles, he obtains a diameter of the sphere of the Fixed stars of 34,589,200 German miles; and, by the proportion of diameter to periphery, namely 7 to 22, he gathers the circumference of the sphere of the Fixed stars as 108,708,914 German miles. Dividing these by 24 hours, it follows that any one of the Fixed stars on the Equator traverses in each hour 4,529,538 — that is, more than forty-five hundred thousand German miles; in each minute of an hour 75,492, that is, more than seventy-five thousand; and in each second 1258, that is, more than twelve hundred German miles, of which 15 make one degree of the greatest circle on the earth. Or, if we believe Cardano, Book 5 of *De proportionibus*, propositions 58 and 218, and experiments often confirmed, says Mästlin — Cardano, who says that the artery of a man of temperate nature beats about four thousand times in one hour — it follows, he says, that in one beat of the human artery the said star traverses 1132, that is, more than eleven hundred German miles, and the primum mobile still more, if it is placed higher than the eighth sphere; *which surely exceeds all belief*, Mästlin concludes. Finally, in the Additions, or notes, to the same *Narratio prima* of Rheticus, page 119 (it should be 115, but the printers erred), he assumes a distance of the Fixed stars not of 14,000, Tycho's, but one still a little smaller, namely 13,500 terrestrial semidiameters, and so a diameter of the sphere of the Fixed stars of 27,000 semidiameters of the earth, that is, 23,220,000 German miles; from this he gathers the periphery of the celestial Equinoctial as 72,977,143. Dividing these by 24, he computes 3,040,714 German miles for each hour; and when these are divided again by 4000 beats of the human artery, there result for each beat 760 German miles, to be accomplished by any one star placed on the Equator of the eighth sphere. *But this is very absurd to believe*, Mästlin concludes there; [Margin: Mästlin's headlong verdict.] indeed, a little later he does not hesitate to say: *Whether this is to be believed of a natural celestial body, and not to be accepted as absurd and simply impossible, anyone will judge, if only he enjoys some use of reason. These and all absurdities of this kind are banished far from the hypotheses of Copernicus.* So if we listen to this man, either we must be mad and devoid of the use of reason, or we must certainly judge that it was impossible for God, as author of nature, to grant naturally to the Fixed stars so great a speed that they traverse 760 German miles in each beat of the human artery.

[Margin: Kepler's calculation for the speed of the Fixed stars, or of the Earth.] II. Let Mästlin be followed by his pupil Kepler. First, in the *Epitome of Copernican Astronomy*, Book 1, page 107, he affirms that it is more likely that

nature expresses a proportioned and small motion in the small Earth than, in the most vast heaven, a motion incredibly swift, and one that would surpass the vastness by its speed in an immense ratio. For motion, no less than magnitude, is a Geometrical thing: *To great things, therefore, slowness corresponds, and to small things speed, not the reverse, as we learn in the Harmonics*, he says. And he goes on: if the machine of the World were turned round the Earth, it would accomplish in one minute of an hour about fifty thousand German miles, supposing Tycho's distance of the Fixed stars. But if the Earth turns, those parts of it that rotate in the greatest circle of all accomplish in one minute of an hour only 3 German miles and three-quarters: a space that is neither the thirteen-thousandth nor the twenty-thousandth part of the space to be traversed by the Fixed stars. Again, in the same *Epitome*, Book 4, page 500, he tries to establish the diurnal motion of the Earth from the same speed, saying: *For if the outermost sphere of the Fixed stars has at least 4,000,000 diameters of the Sun in its diameter, its circumference will be 12,566,370 long. If the whole of it is turned within 24 hours, then in one hour 523,600 will be turned; in one minute 8727; in one second, which about equals a man's pulse, 145 diameters of the Sun will pass by, of which each is not less than 13 thousand German miles. So in the space of time in which the artery is once dilated and contracted again, a doubled pulse, about seventy-five hundred thousand miles of the greatest circle would be turned; and Saturn, in an orbit two thousand times narrower, will still cross almost 4000 miles.* But here he uses the distance of the Fixed stars that is owed to the Copernican hypothesis, with the annual motion of the Earth supposed — which has no force against the hypothesis of the standing Earth, in which the distance and the speed of the Fixed stars are much smaller. Moreover, the same Kepler had reasoned thus in the book *De stella nova*, on the new star seen in Serpentarius, chapter 16: if the Earth is moved with a diurnal motion, the parts placed on its Equator will accomplish 240 German miles in one hour; but since its centre accomplishes 740 German miles in each hour by the annual motion, if these are added to those, they make 980, or nearly a thousand German miles, which some city placed under the Equator would have to complete in one hour at midnight; and, a few things that are not to our purpose being interposed, he continues: *Nor indeed should this passage through a thousand miles in one hour still seem incredible to you. I bid you consider the proportion of the density of the air to the density of the aether, which I demonstrated in the Optics; from it, it follows that the passage of a thousand miles in one hour through the aether is calmer by many parts — an incredible number of them — than is the passage of one mile in one hour through our air.* Having laid this down, he passes to the Ptolemaic hypothesis and affirms that everything in it is found more incredible. For he says: *In that hypothesis the semidiameter of the sphere of the fixed stars holds twenty thousand semidiameters of the earth; the circumference therefore will be of sixty-three thousand.* [Margin: Kepler's slip.] This slip is manifest, but pardonable: he ought to have taken the diameter as 40,000 semidiameters of the earth, and, as 7 is to 22, so to make it to a circumference of about 126,000. From his own calculation, however, he gathers that in one hour a Fixed star must pass over

2625 terrestrial semidiameters, each of which contains 860 German miles. After this he repeats his own saying: *It is more credible that a subject be large without motion than that there be a large motion in a small subject*; and further below: *It is more difficult to intensify an accident beyond the measure of its subject than to have a subject without an accident* (and speed is an accident): *Copernicus therefore acts more plausibly, who enlarges the orb of the fixed stars without motion, than Ptolemy, who enlarges the motion of the fixed stars with an immense speed.* Throughout that whole discussion, however, he uses the proper motions of the Planets towards the East, showing that they are proportionally slower the farther they stand from the Earth; whereas, if the diurnal motion were attributed to the Fixed stars, the passage would run from Saturn, the slowest, to the Fixed stars, the swiftest. In this there is a foul — not to say a crafty — equivocation: for the Fixed stars and the Planets ought to be compared in the same genus of motion, not in a different one, as we shall teach below.

[Margin: Galileo's defence of Kepler.] III. Galileo, however, siding with Kepler in Dialogue 2 on the system of the World, page 198 of the Latin version, brings forward, intending to resolve it, an objection [instantiam] of Chiaramonti against Kepler, which runs as follows. Kepler is mistaken when he says that in the sphere of the Fixed stars the accident — that is, the speed — is increased beyond the measure of the subject; for in whatever proportion the circumference of the sphere is increased, in the same proportion the motion, or the space to be traversed by the moving body, is increased too. Galileo tries to resolve this by saying that Kepler was not so dull of wit as not to see it, but that by "the measure of the subject" he understood the norm and example of the other celestial bodies, which are slower the farther they are removed from the centre, as appears in the Planets and in the Medicean stars. But this resolution is frivolous, since the comparison is not made within the same species of motions, as will be said in the resolution of the second argument.

[Margin: Lansbergen's calculation for the speed of the Earth and of the Fixed stars.] IV. Longomontanus too, in Book 1 of the *Theorics*, chapter 1, calls the speed of the Fixed stars incredible. Lansbergen, for his part, in the 6th argument for the diurnal revolution of the Earth, says that any terrestrial point on the Equator accomplishes 225 German miles in one hour, and in one minute (that is, a second) the sixteenth part of a mile — which bears a fitting proportion to the motions we experience in nature, since a cannon ball traverses the sixteenth part of a German mile in one minute. But if the eighth sphere were moved, it would have to run through 643,848 miles in one minute [?]; and Saturn, if it were turned by the diurnal revolution, would complete 930 miles in one minute — which he thinks utterly absurd. [Margin: The speed of a cannon ball.] Lansbergen admits, however, on the strength of the Landgrave of Hesse's experiment, that a cannon ball runs through half a German mile in one minute of an hour before it strikes the ground; for Kepler affirms, at page 108 of the *Epitome*, that the Landgrave and Tycho tested this.

[Margin: Mulerius's calculation for the speed of the Fixed stars.] Nicolaus Mulerius, by contrast, at page 322 of the *Frisian Tables* [tabularum Friſicarum], supposing Tycho's distance of 14,000 semidiameters of the earth, or 12,040,000 miles, says that the great circle in the Firmament extends for 88,000 terrestrial semidiameters, or 75,680,000 miles, and that the hourly motion of a Fixed star on the Equator is therefore 3,153,333 miles. Yet from this speed he rightly rises to praise the power of God, exclaiming with the Psalmist, *The heavens tell the glory of God, etc.*, and His goodness, which for our sake moves the Firmament with so great a speed, repeating that verse of Psalm 8, *What is man, that you are mindful of him?* So far is he from gathering any absurdity from it.

[Margin: Gassendi's calculation for the speed of the Earth and of the Fixed stars.] V. Lastly, Gassendi, in Letter 2, *De motu impresso a motore translato*, page 111, rightly points out that there is no reason why it should be objected to the Copernicans as an absurdity that we, in some part of the earth — namely under the Equator — would be moved with so great a speed that a cannon ball would scarcely attain it. But he adds that the Copernicans can throw back at their opponents an incomparably more absurd speed of the Fixed stars. For a point of the Earth under the Equator, where the motion is swiftest, would run through about two hundred fathoms [Orgyas], or toises, in one second of an hour, that is, in the interval from one beat of the human artery to the next. *But since the circumference of the Firmament*, says Gassendi, *is, by the common opinion, more than fifty thousand times greater than the circumference of the Earth, a point on the circumference of the Firmament must in one second of an hour run through fifty thousand times as many fathoms.*

[Margin: Our calculation for the speed of the Fixed stars.] VI. So much for the measures of the Copernicans, if you except Mulerius. For these, however, the Reader may consult our Table of the speed of the Fixed stars, which we gave in Book 6, chapter 7, number 18. There we gathered that speed from other men's distances of the Fixed stars from the earth, and a much greater one from our own hypothesis. For in one second of an hour, or the interval of one pulse of the human artery, any Fixed star on the celestial Equator traverses, on the Ptolemaic reckoning, at most three semidiameters of the Earth; but on our hypothesis 152⅔ terrestrial semidiameters, that is, 629,128 Bolognese Italian miles, which are 157,282 German miles, according to what was said in Book 2, chapter 7, about our measures of the Terrestrial globe. So far, then, are we from wishing that speed diminished that, through our hypotheses, we rather make it — and admit it to be — about seventy times greater than it is in Tycho's hypothesis, and fifty times greater than in the Ptolemaic. And yet, this notwithstanding, we shall shortly show that the Achilles of the Copernicans has feet of clay, and weak ones. Let the argument first be put in form.

[Margin: Syllogistic form of the argument.] VII. *The diurnal motion is to be attributed rather to that body whose speed is more credible and more proportioned to the movable subject. But if the diurnal motion is attributed to the Earth, its speed is more credible, and more proportioned to the terrestrial mass, than if it is attributed to*

the sphere of the Fixed stars. Therefore the diurnal motion is to be attributed to the Earth rather than to the sphere of the Fixed stars. The MAJOR is evident of itself, and is clear also from the fact that Nature and God do what is easier in itself and more intelligible and credible to an intellectual creature. The MINOR is proved from the fact that the speed of the Earth turns out smaller by very many times than the speed of the Fixed stars, as was shown from number 1 to 6; and that it is more congruent with the measure of its subject, the mass of the Earth, than the speed of the Fixed stars is with the immensity of their sphere, as was shown in numbers 2 and 3.

[Margin: 1st Reply.] The reply is, first — the Major being granted, but not yet conceded (for God and Nature do not always do what is more credible to us because it is easier) — to deny the Minor as to both its parts. Thus the consequence of the argument adduced for the first part of the Minor is denied: for it does not follow that a speed is more credible precisely because it is smaller, and more incredible because it is in reality greater, unless the excess of the greater over the smaller is also contrary to sense, or out of proportion to the capacity of the subject and to its motive power, and the shortfall of the smaller is in conformity with sense. That is not what happens in our case. For the motion of the Fixed stars is indeed evident to sense, and their speed is very slight to sense, so much so that in one second of an hour — indeed in one minute of an hour — they scarcely seem to move. But the motion of the Earth is nothing whatever to sense; hence its speed is not a smaller speed but the utmost slowness — indeed no motion at all, if we stand by the physical evidence we have from sense — and so any speed of the Earth whatever is contrary to sense. If the comparison were made between two moving bodies of whose motion we had physical evidence, then indeed that speed would seem more credible which was smaller, or at least so great as not to offend sense, than one which offended sense by excessive rapidity, if the eye tried to follow it. For to the intellect no speed can be excessive, since the intellect comprehends a much greater one.

[Margin: The speed of the Fixed stars is proportioned to the subject.] As for the other part of the Minor, concerning speed proportioned to the subject, this too is denied, as I said, together with its proof. For if the comparison is made, as it must be, in the same genus or the same species of motion — namely in the diurnal motion — then however much the semidiameter of any sphere grows, the circumference, which is the space to be traversed by the diurnal motion, grows by just as much. Therefore, just as there would be nothing incongruous in the speed of the par- ts of the terrestrial surface, even if it were four thousand times greater than the speed of the parts that stand a single pace from the centre of the earth, so neither is the speed of the parts of the sphere of the Fixed stars incongruous, even if it is many thousands of times greater than the speed of the parts of the terrestrial surface. For it happens in this case just as if one pace of some giant were compared with one pace of an ant: each is proportioned to the legs of its own subject. Granted that a thousand paces of the ant are contained in a single pace of the giant, and that on account of this

number the pace which for the giant is a single and very easy one would seem excessively swift to the ant, through the multiplicity of its small parts. How sophistically, moreover, the comparison of the diurnal motion of the Fixed stars is transferred to the motion of the Planets towards the East will be clear from the resolution of the second argument, to be proposed shortly. So much for the comparison of the spheres as to their surfaces. For if they are compared as to their masses, the excess of the mass, or solidity, of the greater sphere over the smaller is greater than that of surface over surface, since the former is in the triplicate ratio of the diameters. But this will be clearer from what is to be said in chapter 30, number 8, where it is treated expressly.

[Margin: 2nd Reply.] The reply is, 2ndly, to concede the Major if that speed is more credible to the intellect with the evidence of the senses kept intact, and the authority that binds us; and to deny it if it is more credible to the intellect taken precisely — an intellect not only abstracting from sense and from binding authority, but even judging against both. With this distinction supposed, the Minor is then denied. For the Copernicans, against the evidence of sense, deny motion to the Fixed stars and grant it to the Earth[40], and are wholly bent on following mere intelligible reasons, with sense neglected or corrected, and with sacred authority dragged without necessity from the literal sense to a figurative and foreign one. We, indeed, are not yet disputing about Authority; yet we ought not always to forget it among our replies to their arguments. [Margin: A witty saying of Athanasius Kircher.] And not without wit did Athanasius Kircher say, in the *Magnes*, page 539: *God commends himself by the speed of the Sun, and you cannot believe it?* — namely in those words: *He has exulted like a giant to run his course.*

[Margin: 3rd Reply.] The reply is, 3rdly, to turn the argument back — not indeed against the Semi-Copernicans, who admit only the diurnal revolution of the Earth, but against the Copernicans, who add the annual one as well. For from the annual revolution there follows an immense distance of the Fixed stars, such that the diameter of the great orb becomes a point with respect to it, and indeed a most vast gap between Saturn and the Fixed stars, idle and destined for no stars. Just as they, then, to soften its incredibility, have recourse to the wonderfulness of the Power and Majesty of GOD the Maker, so let them allow the Omnipotence and Majesty of the same GOD to be commended by the remarkable speed of the Fixed stars — especially since the divine Power and Wisdom shine out much more in assigning to a sphere of moderate magnitude a remarkable speed, yet one serving some use, than in extending a mass into immensity without any motion or action equivalent to motion, and in such a way that it cannot appear to what use that inert mass, empty of sensible bodies, serves. To me, certainly, he would seem a man of greater genius and skill who built some great ship, full of sailors, soldiers and merchants, so that by the art of either sails or wheels it flew across a thousand miles of the Ocean in the space

[40]printed *Ter-tæ*

of one hour, than one who raised a crag right up beyond the clouds, but bare, and, its summit excepted, furnished with no grasses, plants, animals, gems or minerals.

II. Argumentum à Proportione motuum & Interuallorum, Subiectorumque Mobilium.

II. The Argument from the Proportion of the motions and of the Intervals, and of the Movable Subjects.

VIII. I would certainly be ashamed of this argument, since it is sophistical and rests on a manifest equivocation, if they did not press it so seriously on the occasion of the first argument related in this chapter — above all Kepler, in chapter 16 of *De stella nova* in Serpentarius, where he reckons up his reasons thus. [Margin: Kepler's calculation for the proportion of the celestial motions to their intervals.] *In the hypothesis of Copernicus*, he says, *the globe of Saturn passes over about 300 German miles in one hour; that of Jupiter 400; of Mars 600; of the Earth 740; of Venus 800; of Mercury 1000* — he is speaking of the proper motions towards the East — and he adds: *A beautiful proportion indeed, where the swifter is always the one nearer to the Sun, which is at rest and is the dispenser of all motion.* Then, having said that in Ptolemy's opinion everything is found more incredible, he adds that the Fixed stars, if they are moved, must pass over 2625 semidiameters of the earth in one hour, each of which contains 860 miles. *See here*, he says, *what an immense difference: Saturn, which in Ptolemy is next to the Fixed stars, so that it all but touches them, passes over 300 miles in one hour for Copernicus; for Ptolemy, 2,257,500 miles. It is therefore to be believed swifter in Ptolemy than in Copernicus by 7525 times. Whoever tries to grasp this incredible speed with his mind will be just as wearied — and even more severely — as one who tries to grasp the Copernican immensity. Meanwhile, Philosopher, weigh this: that a proportion of the accident to its subject is much more wanting here than anyone can rightly find wanting in Copernicus a proportion of one part of the World to another.*

[Margin: Galileo's discourse for the same proportion.] IX. On exactly the same reasoning Galileo, in Dialogue 2 on the system of the World, page 84 of the Latin, judges Ptolemy's hypothesis improbable, because, with all proportion removed, the order of motions manifest in nature is disturbed. *The order*, he says, *is this: the greater an orb is, the longer the time in which it finishes its revolution, and the smaller ones in a shorter. Thus Saturn, etc. No less perceptibly do we see in the Medicean stars that the one nearer to Jupiter completes its revolution in the shortest time, that is, in about forty-two hours; the next in three and a half days; the third in seven days; and the most remote in seventeen days. And this concordant tenor will not change at all, so long as we assign to the terrestrial globe a motion of 24 hours about itself. But if we establish the Earth as immobile, then it will be necessary to pass from the slowest sphere, Saturn's, to the incomparably greater sphere of the Fixed stars, and to attribute to it a revolution of 24 hours, etc. But if we assign mobility to the Earth, the order of the periods is perfectly consistent, and the passage*

runs from the most sluggish sphere, Saturn's, to the Fixed stars, wholly immobile. He repeats similar things in the same dialogue, page 199, where, refuting the replies of the *Antitycho* — that is, of Chiaramonti — on behalf of the Ptolemaic system, he says: *But this conflicts with the architectonic rules of nature herself, which observes this in the measure of the smaller spheres (as we see in the Planets, and most perceptibly in the Medicean stars): that she turns the smaller orbs round in smaller times too. Hence the time of Saturn's revolution is longer than all the times of the other, smaller spheres, being completed in 30 years. Now to pass from this sphere to another, very much greater one, and to fix its revolution at only 24 hours — this, one might not unreasonably say, is to wander outside the rules of measure.* [Margin: Lansbergen's similar discourse.] Here Galileo plainly Keplerizes, as does Lansbergen too in his commentaries on the diurnal and annual motion of the earth, who argues in the same way about the order already mentioned. But we shall soon uncover the equivocation, once we have bound the argument to the laws of the syllogism.

[Margin: Argument 2 reduced to Form.] X. *The diurnal motion is to be attributed rather to the sphere that is the smallest of all than to the one that is the greatest of all. But the sphere of the Earth is the smallest of all the spheres of the world, and the sphere of the Fixed stars the greatest. Therefore the diurnal motion is to be attributed to the sphere of the Earth rather than to the sphere of the Fixed stars.* The MINOR is called into doubt by no one. The MAJOR is proved by induction from the manifest motions of the spheres: for the greater each sphere is, whether of the Planets or of the satellites of Jupiter, the slower, or the longer in time, is its motion; and the smaller the sphere, the swifter, or the shorter in time, is its motion. On the other side, the shortest revolution among the manifest revolutions of the stars is that of 24 hours, and so it is the smallest.

[Margin: 1st Reply.] I reply, 1st, by denying the Major, and by distinguishing the first part of its proof. That part we grant rather than concede, if the discussion is about the proper motion of the Planets and of the Satellites of Jupiter towards the East — yet in such a way that not Saturn's sphere is admitted to be the most sluggish of all, but the sphere of the Fixed stars, since it cannot naturally complete its revolution towards the East except in about 26,000 years, or, according to Ptolemy, 36000. Nor is that induction to be conceded except of the celestial motions, as being manifest to sense, and so with the comparison made between those spheres of the world that are, beyond controversy, apparently moved — not, however, of the sphere of the elements, much less of the terrestrial one, whose immobility, rather than its motion, is manifest to sense. But that same first part of the proof we flatly deny, if the discussion is about the apparent motion common to all the stars, namely towards the West, which is called the motion of the primum mobile and could be called the motion of the common movable [communis mobilis], if not by being carried along, at least by imitation. For the greater the sphere, or the higher the star, that is moved by such a motion, the swifter is its diurnal revolution; and the smaller or lower, the slower — speaking here too of the spheres whose motion appears and is manifest to sense.

Hence the sphere of the Fixed stars revolves to the same Meridian in 24 hours, Saturn a very little more slowly, and so on for the rest, so that the Moon, the lowest of all, revolves towards the West from a Meridian back to the same Meridian only in 24 hours and about 48 minutes besides. The second part of the proof is perfectly true, namely that the revolution of 24 hours is the shortest of the manifest revolutions.

[Margin: 2nd Reply.] I reply, 2nd, by denying the Major, and by likewise denying the first part of its proof, without any distinction. For there are not in reality two motions in the Fixed stars or in the Planets, one towards the East and the other towards the West. Rather, as we laid down and set out, with many others, as the more probable view in Section 2, chapter 3, numbers 6, 7, 8 and 14, there is a single motion, along spiral or helicoid — or, as it were, screw-shaped — lines. Because it does not perfectly attain the idea of the primum mobile, but falls short of it in the time of revolution to the same Meridian by so much the more as it stands farther from it in place and nearer to the earth, it therefore seems, through that very slowness in attaining it, to be a motion towards the East. Nor, to save the appearance of this motion and to satisfy the senses themselves, is there any need to acknowledge that slowness as a distinct species of motion; it is enough to imagine a motion towards the West, slower and slower, so that, when the slownesses of many days are added together, the lower spheres, or the Planets, seem to be abandoned more and more by the higher ones, especially by the Fixed stars, and to be left behind towards the East. This common motion towards the West, moreover, is more manifest than its modification, or retardation, towards the East, since it is observable every day, whereas that retardation, if you except the Moon, requires several days to become manifest from observation. Therefore, in the order and proportion of motions, the induction must be made either solely, or at least preferably, according to this motion towards the Setting; and in it the motion is swifter in the greater spheres or the higher stars. With every right, then, is the first part of that proposition denied which was adduced for the proof of the Major.

[Margin: 3rd Reply.] I reply, therefore, 3rd, by turning the argument back thus. *The diurnal motion is to be attributed rather to the sphere which is the greatest of all and the most remote from the centre of the World than to the one which is the smallest and nearest the centre. But the sphere of the Fixed stars, or some sphere loftier than it, is the greatest and highest; the Earth, however, is the smallest and nearest the centre of the World. Therefore, etc.* The MINOR is evident. The MAJOR is proved both from the nature of the sphere and of the circle — in which, if there is a common motion of all the parts, those parts move most swiftly that are most remote from the centre — and chiefly by an induction made from the motions that are the most manifest of all in the stars. These are the daily motions towards the West and the revolutions to the same Meridian; for it is established that motions of this kind are more vigorous, and are completed in a shorter time, by the greater spheres or by the higher stars, as was said in the 2nd reply. Therefore, etc. And indeed, unless this is so, the manifest

order in the apparent motions of the bodies of the world is disturbed, and that most ancient Harmony of the heavens is taken away which, following Plato and Hesiod, Cicero, Macrobius, Ficinus, Glareanus, Zorlinus and very many of the Harmonists admired and received. For they assigned to the supreme sphere either the Mese or the Nete — that is, the highest-pitched of voices and strings — on account of its swiftest motion, and to the Moon the Hypate, the lowest-pitched, on account of its slowest motion. Granted, fewer others, looking to that slowness of the apparent revolution towards the East, attributed the Nete to the Moon and the Hypate to Saturn — namely Nicomachus and Boethius, as I said in Book 7, Section 1, chapter 1; but these had fewer followers among the Musicians. Yet if both opinions are to be received, and the one motion is to be distinguished into two, what more admirable order of divine Providence could shine out in these things than that a compensation should be made from the highest to the lowest and from the lowest to the highest, in running up and down through this harmonic system, and that the sphere whose motion towards the East was swifter should have the slower motion towards the West? This compensation, however, and this most beautiful antithesis, is taken away if the common motion, which evidently appears to sense in the stars, is attributed to the Earth, whose immobility is evident to sense.

Away with that sophism by which Kepler, Galileo and Lansbergen have tried to blind the eyes of the unskilled — considering only the appearance of the celestial motion towards the East, as though this were the single or chief motion among those manifest to sense, while meanwhile concealing the evidence of the common motion towards the West.

III. Argumentum à Repugnantia Motus proprij cum Motu Primi Mobilis in eodem ſubiecto.

III. The Argument from the Incompatibility of the Proper Motion with the Motion of the primum mobile in the same subject.

[Margin: Kepler's argumentation, ineffective.] XI. *If the first motion*, says Kepler in the *Epitome of Copernican Astronomy*, Book 1, page 104, *is in the celestial orbs, then two motions are in the same subject: one common to all the spheres, the other proper to each sphere. But it is much more probable that the first motion and the second motions are distinct in their subjects, so that the second motions, which are many, are each in its own sphere, while the first, which is single, is also in a single body, the Earth.* An ineffective argumentation indeed — as if the concept [ratio] of animal, because it is generic and common to every species of animate beings, had to exist separately, in subject and in reality, in a single Idea or in something else; or — to give an example in a sensible accident, of which kind apparent motion is — as if the common concept of colour had to be in a single subject, and whiteness, blackness and the other differences in the rest. But, you will say, if the two motions are in the same subject, they will fight each other. [Margin: Galileo's argumentation.] And so Galileo, in Dialogue 2 on the system of the

World, page 83 of the Latin, said: *If that great motion is attributed to the heaven, it must necessarily be made contrary to the particular motions of all the Planets, each of which, beyond controversy, has its own proper motion from West towards East, which we must then make to be carried off in the contrary direction, that is, from East to West, by that most rapid diurnal motion; whereas, if the rotation of the Earth about itself is asserted, the contrariety of motions is removed, and the single motion from West to East is accommodated to all the appearances and satisfies them all exactly.* [Margin: And Lansbergen's.] Lansbergen drives home the very same argument in his commentaries on the motion of the Earth, affirming that it is impossible for the eighth sphere to be moved by two contrary motions; and so he grants the proper motion towards the East to the Fixed stars (in which he differs from Copernicus), but attributes the common motion to the Earth.

[Margin: Gassendi's opinion.] XII. Gassendi strives to carry this point with much weightier formulas, in Letter 2, *De motu impresso a motore translato*, page 109, where he speaks thus of the motion of the primum mobile: *Although the matter might perhaps seem tolerable in some way, if that whole machine were carried round towards the Setting by a single and simple motion; yet since, on the other hand, so many Planets are also carried round towards the Rising, what could be more absurd than to feign, above the Planets and above all the Fixed stars and even the crystalline spheres, a most vast sphere of the primum mobile, which itself strains against the lower spheres as they strive towards the Rising with their own slow motions, and snatches them all away towards the Setting with incredible speed? Can anything be more violent, and yet be thought to be perpetual in the nature of things? Can anything be more tortuous, and yet be attributed to nature, which always proceeds to where it tends by the shortest and most level path?* And after inserting a few things in favour of the simplicity of the terrestrial motion, he teaches that the rapt motion of the primum mobile cannot be communicated to the lower orbs, which are not solid; and that even if they were solid it could not be, because they lack little handles by which they might be gripped by the higher orb. But this does not tell against the many others who, as I taught in Section 2, chapter 3, do not posit the primum mobile as distinct from the sphere of the Fixed stars and from the motions of the Planets, and yet attribute the diurnal motion to them. Let the argument now be put in form, as follows.

[Margin: 3rd Argument in form.] XIII. *It is impossible for the same movable body to be moved by two contrary motions; or, if they are not really contrary motions, *the appearance of contrariety is nevertheless to be avoided, as far as possible. But if the diurnal motion were attributed to the Fixed stars and the Planets rather than to the Earth, the same movable body would be moved by two contrary motions, or at least the appearance of contrariety would not be avoided as far as possible. Therefore the diurnal motion is not to be attributed to the Fixed stars and the Planets rather than to the Earth.* The MAJOR seems clear enough, and is to be denied by no one. The MINOR was proved in number 11: for one motion of the same movable body would either be, or would appear to take place, towards the East, the other towards the West; these are contrary termini, and therefore specify contrary

motions; and this appearance of contrariety would be very easily avoided by attributing the diurnal motion to the Earth.

[Margin: 1st Reply.] I reply, 1st, granting the Major, by denying the Minor and both parts of its proof. For there is no apparent contrariety in the motions already mentioned, except in the imagination of those who distinguish this motion, in reality, into two motions towards contrary quarters. Those, by contrast, who conceive it without that fiction — as a single motion towards the West, distinguished only by slowness or speed from another motion made towards the same quarter — remove from motion of this kind not only real but even apparent contrariety. If you nevertheless press that, by the very slowness by which they are left behind by the swifter movable, they seem to recede towards the East, and that the appearance of contrariety cannot be removed altogether, I reply that not even by granting the diurnal motion to the Earth is that appearance avoided; for the same things would appear as now. Therefore, if some cannot correct their fancy [phantasiam] so as not to see two contrary motions, they will not overcome it in this way either, if they choose to cling to the appearance. But what deception, I beg you, or what perversion is this: that of two movables running round in a circle towards the same part, the one that moves more slowly should be said, or seen, to run towards the opposite part? Read again, I beg you, what we have said about this apparent contrariety in Section 2, chapter 3, from number 6 to 8 and from 14, and in the scholia of the same chapter.

[Margin: 2nd Reply.] I reply, 2nd, by turning the argument back against the contrariety which, in Copernicus's hypothesis, has to be posited among the motions of heavy bodies as they are carried downwards, if they have been thrown obliquely towards the West, and in many other movables of this kind. If that contrariety is not absurd, neither will the apparent contrariety in the motions of the stars be absurd.

IV. Argumentum à Simplicitate Motuum.

IV. The Argument from the Simplicity of Motions.

XIV. But, they say, it cannot be denied that the simplicity of motions is greater if a single motion towards the East is attributed to the Planets, or even to the Fixed stars, without any admixture of a diurnal motion to be represented towards the West by spirals or in some other way, and if the appearance of the other motion is transferred to a single motion of the Earth. [Margin: Copernicus's opinion in favour of economy of motions.] Hence that saying of Copernicus in Book 1, chapter 10: *But the sagacity of nature is rather to be followed, which, just as it has most of all taken care not to produce anything superfluous or useless, so has rather often endowed one thing with many effects.* This, moreover, is the third reason by which Galileo, in Dialogue 2 on the system of the World, page 84, confirmed the diurnal rotation [volutationem] of the Earth. For he grants that whether the celestial motions towards the East and the West are contrary

or not is a dispute about words; but he adds: *I know that in reality it is much simpler and more agreeable to nature if we can save everything by one single motion than if we introduce two motions, which, if you do not want to call them contrary, you may call opposite. Nor do I condemn that introduction of opposite motions as impossible; nor do I affirm that a necessary demonstration is constructed from its negation, but only that something at least of weight is added towards probability.* [Margin: Gassendi's opinion in favour of the same economy.] With this agree those words of Gassendi in Letter 2, *De motu impresso a motore translato*: *With the Earth indeed turned towards the Rising — and nothing is more economical than this — their own slow motions towards the Rising will be left to the Planets themselves; and the motion which appears to be in them, as well as in the Fixed stars, towards the Setting will appear from the single turning of the Earth towards the Rising; so that this sole and simple turning is equivalent to that primum mobile, and meanwhile frees the lower orbs from that so great rapidity, violence and entanglement.* But, to say no more of these things, let the argument be framed in the following way.

[Margin: 4th Argument [?], enclosed in its form [?].] XV. *Of two motions, that one is to be chosen which is simpler and single, rather than the one which is multiple and composite. But the diurnal motion of the Earth is simpler and single, that of the Fixed stars and the Planets multiple and composite. Therefore the diurnal motion of the Earth is to be chosen rather than the diurnal motion of the Fixed stars and the Planets.* The MAJOR rests on that most widely received axiom of the Peripatetics: *What can be done by fewer things is done in vain by more.* Galileo, in Dialogue 2 on the system of the World, page 88, with excessive subtlety denies that the limitation "equally well" is to be understood in this axiom, because what is not done well, or not with full goodness, is not the same; whereas the axiom supposes that what is done by more things or by fewer is the same. The MINOR is easily proved: for once the diurnal motion of 24 hours is assigned to the Earth, there is no need to compound another motion towards the West with the proper motions of the Fixed stars and the Planets; and so the single and simple motion of the Earth will represent the appearance of all the diurnal motions.

[Margin: 1st Reply.] Someone might reply, 1st, by distinguishing the Major: granting it if other things stand equally on both sides — or if evidence gained through the senses, or even authority, which is superior to all reason, is equally satisfied — but otherwise denying it. In the case proposed, however, there stand against it both the Authority of Sacred Scripture, which attributes the diurnal motion to the stars and immobility to the Earth, and (what belongs to this place) the evidence of the senses concerning the diurnal revolution of the stars and the rest of the Earth.

[Margin: 2nd Reply.] I reply, however, 2nd, granting the Major, by denying the Minor. For more motions, both in number and in species, are multiplied in Copernicus's hypothesis, with the diurnal motion attributed to the Earth, than if it is attributed to the heaven and the stars — provided that all the conditions of motions which the diurnal motion given to the Earth necessarily draws with it

are considered, and that, on the other side, that hypothesis of the resting Earth is chosen which, by a single spiral line, represents all the varieties of motions in each of the Planets and in the sphere of the Fixed stars, according to what we have said so often, but above all in Section 2 of this Book, chapter 3, from number 14. For in this hypothesis there is a single motion of the Eighth sphere towards the West, but one that falls short little by little of the most perfect Idea of the first motion, which shines in the mind of the Intelligence or Intelligences that move that sphere along a spiral line; and this motion, perhaps, on the first day or the first three days before the Sun and the stars were made, was completed by a most perfect revolution of the light to the same Meridian. In the seven Planets, likewise, there is a single motion, also towards the West, but slower in the lower ones, and carried out by the Intelligences obliquely along spirals, looser in some cases and tighter in others. And so in all there are eight motions, with the little appendages of motions by which the satellites revolve about Saturn and Jupiter, which are not under discussion in this place; in the motion of heavy and light bodies, moreover, a simple motion along the shortest and simplest straight line suffices. But in Copernicus's hypothesis, besides the motions of the Seven Planets and the eighth — which he attributes to the terrestrial axis, slowly inclining itself against the order of the signs, while the semi-Copernicans attribute it to the Fixed stars — it is necessary to posit a ninth motion, really distinct, and to attribute it to the earth. [Margin: How mixed the motion of Heavy and Light bodies is, if the Earth is moved.] Once this is posited, in order that the countless experiments of the motions by which both inanimate and animate things are moved on the Earth, in the Water, and in the Air nearer to the lands may be saved, it is necessary — besides the straight motion of heavy and light bodies and the peculiar motions of animals, winds, clouds, etc. — to posit a circular motion included in those motions, though unknown to us or not seen by us. From these there arises a motion mixed of straight and circular: whether it be parabolic, according to what was said in the scholia of chapter 4 — which is certainly not the shortest, but must be completed along a longer path — or of some other figure, on which matter see below, chapter 17. Nor is this the end of the perplexities. For one must imagine that a clod of earth, torn from the earth's surface near the Poles and thrown up there along the perpendicular, moves with that slowness with which the circles of the earth that are parallel to the terrestrial Equator, but near its poles, are moved; but that, if the same clod is carried by someone in a box to another parallel, or is thrown upwards from the North towards the South with an oblique cast, it ascends and descends with a continually changing proportion of speed, so as to move more swiftly over the parallels nearer the Equator; and this although it is not joined to the Earth in the way that the Fixed stars are joined to the eighth sphere; and so that it changes innumerably its property of speed, and that line of its motion turns out to be composite in many ways. But if this is not a real composition, but a diverse affection and modification of a

single motion, it is much truer that in each Planet there is no real composition of motions, but only diverse affections of one motion.

[Margin: 3rd Reply.] I reply, therefore, 3rd, by turning the argument back thus: *Of two motions, that one is to be chosen which is simpler and single, rather than the one which is multiple and composite. But the diurnal motion attributed to the Fixed stars and the Planets, together with rectilinear motion for heavy and light bodies, is simple and single in each of the simple bodies; it is not such, however, if the proper motions are attributed to the Fixed stars and the Planets and the diurnal motion to the Earth. Therefore, etc.* On the MAJOR we both agree. The MINOR has already been set out and proved in the 2nd reply: for in place of eight motions in the heaven, and two in the Elements — one upwards, the other downwards — a ninth, of the Earth, is posited; to the rectilinear motion of the elements a mixture of curvilinear motion is added; and their ascent and descent takes place along a longer path than if they were carried by their own nature along a rectilinear and perpendicular course. The Copernicans, therefore, ought to have looked round at these things more attentively, or else not to have dissembled the multiplicity of motions, and of accidents in motions, which lies hidden in their own hypothesis.

V. Argumentum ab Inæquali participatione Motus Diurni, ſeu ab Inæquali Velocitate eorum, quæ motu diurno mouentur.

V. The Argument from the Unequal Participation in the Diurnal Motion, or from the Unequal Speed of the Things that are Moved by the Diurnal Motion.

XVI. Self-love [Philautia] is, to be sure, a flattering thing: each of us has long been affected by it towards his own opinion, and has grown so used to it that he does not recognize in his own hypothesis the very same spots or blemishes by which he thinks the hypotheses of others disfigured. Look, indeed, at Galileo in Dialogue 2 on the system of the World, page 85 of the Latin version, speaking thus against the common hypothesis, which grants the diurnal revolution to the Fixed stars: *The fourth difficulty is the immense disparity between the motions of the same stars, of which some will be moved most swiftly, in the vastest circles, and others most slowly, in the smallest circles, according as these or those are nearer to the poles or less near. This is certainly very inconvenient: both because we see that those whose motion is not doubted all move in the greatest circles, and also because it seems absurd to place bodies that move circularly at immense distances from the centre and to attribute to their motions the smallest circles.* [Margin: Galileo's discourse, but an utterly fallacious one.] These are the very words of Galileo, uttered in earnest, as appears; [Margin: Refutation of the Galilean Argument.] and yet for these words, I well know, any little beginner lightly grounded in the elements of the doctrine of the sphere would get a sound beating from Galileo himself. So there is no need to frame the argument in order to reject its fallacy. For it is no inconvenience that, in the same sphere turned about its own poles by a single rotation, the parts that lie on the circumference of great circles should move

more swiftly than those on the circumference of smaller circles, nearer the poles; rather, it is required by Geometrical necessity, since in the same time the former run through greater arcs and the latter lesser ones, whether that sphere then be large or small. Otherwise, if it were an inconvenience, it would be no less one in the diurnal revolution of the Earth, whose parts placed on the Equator would certainly have to move much more swiftly than the parts in the polar circles or situated near the poles. It is false, moreover, that the stars of whose motion we have no doubt at all all move in the greatest circles. For neither do the Planets, in their proper motion, always run in the Ecliptic — having acquired from it a latitude of several degrees, they describe smaller circles, especially if they are then also at perigee or perihelion — nor does their common motion, which is no less evident to sense in them than in the Fixed stars, since it is both daily and observable every day, take place along the greatest circles, but along circles parallel to the Equator, one after another. Lastly, the circles that are called smallest in the heaven, because they are nearest the Poles, are not called smallest in comparison with the circles of the Earth, but in comparison with the greatest circles of the same heaven or sphere; and in the respect in which they are, and are called, smallest, they are not the swiftest but the slowest — namely in comparison with the motion that takes place in the same time along the greatest circles. There is nothing absurd, then, if, at whatever distance from the earth they stand, they nevertheless describe circles which are the smallest in comparison with the greatest circles of the same sphere, and are not the smallest in comparison with the circles of the Earth. Indeed, if this were something absurd, it would be multiplied more by moving the Earth: for there would be an appearance of unequal speed in the heaven, and a real inequality in the parts of the Earth more or less remote from the poles.

VI. Argumentum ab Inconſtanti Declinatione, ac Velocitate Fixarum.

VI. The Argument from the Inconstant Declination and Speed of the Fixed Stars.

[Margin: Galileo's other argumentation, but an ineffective one.] XVII. Galileo sets out, but gets nowhere. In the same Dialogue 2 on the system of the World, and on the same page 85, he passes to another inconvenience, as he himself calls it, which follows from the diurnal motion attributed to the Fixed stars. *For*, to use his own words, *the stars themselves will vary their circles and their speed (which is the fifth inconvenience): since those which two thousand years ago were on the Equinoctial, and consequently described the greatest circles by their motion, decline in our time many degrees from the Equinoctial, it is necessary that they too have become slower in motion, and have been reduced to describing smaller circles. And it is not far from possible that a time should come in which one of them, always moved before, on being united with the Pole, should stand still, deprived of all motion, and after a rest of some time should begin to move again; whereas the other stars, which without doubt are moved, all describe, as has been said, the greatest*

circle of their orb and turn in it without variation. Are these your inconveniences, Galileo? And are these things said by you in earnest, or in pretence? But let the argument be framed, though there is scarcely need.

[Margin: Form of the 6th Argument.] XVIII. *If the Fixed stars are moved by a diurnal motion, it is necessary that the same Fixed stars at one time describe the greatest circles and be the swiftest, and at another describe smaller and the smallest circles, or even none, and so turn out less swift or least swift, or even not to be moved at all. But this is an inconvenience. Therefore the Fixed stars are not moved by a diurnal motion.* It remains, therefore, that such a motion belongs to the Earth.

[Margin: 1st Reply.] I reply, 1st, granting the Major if a proper motion in longitude is granted besides the diurnal motion of the Fixed stars, but denying the Minor. For this is no more an inconvenience than that the Planets at different times vary either their declinations or their latitudes, and are now swifter, now slower. Or, to draw an example from Copernicus's own storehouse, this is no more an inconvenience than that, in Copernicus's hypothesis, men, fish and birds — who daily, by walking, sailing, swimming and flying, straight or obliquely from the South towards the North or conversely from the North towards the South, vary their declination and their parallels of the Equator — should be moved now more slowly, now more swiftly, with the Earth on which they stand or whose diurnal motion they follow; indeed, that those who live under the poles of the terrestrial Equator should be moved by this motion not at all, or almost not at all. And yet variation of this kind is far more frequent, is entangled in very many perplexities of animate motions, and — what is the chief point — is feigned against all the evidence of the senses; whereas that variation in the Fixed stars as to declination and speed has been confirmed through many centuries by the evident experience of observations, and from it follow many things most worth knowing, and theorems and problems that lead us by the hand to the Glory of GOD the Creator. Of these we have brought forth some that are new and hitherto unheard of, in Book 6, chapter 11, but above all in chapter 19, where in problem 5 we taught the conditions required for a star to be able to reach the poles of the world, and that the star we now call the Polar star never has been, nor will be, exactly at the very Pole of the World; and in Problems 10 and 11, that there are some Fixed stars whose Right Ascension, although their Longitude increases, nevertheless increases in some centuries or periods and decreases in others, by a certain retrograde motion of declination, and that 94 such stars are found in the heaven among those hitherto counted with the naked eye; teaching, moreover, the way of discerning Geometrically the situation of these stars, and of determining the times in which their Right Ascension must increase and in which it must decrease. If Galileo had known this, how specious an inconvenience would he have brought forward against the hypothesis of the diurnal motion of the Fixed stars?

[Margin: 2nd Reply.] I reply, 2nd, by turning the argument back, and by throwing the inconvenience already mentioned back upon the Copernican hypothesis — not absolutely but ad hominem, as they say — in this way: *If*

the Earth were moved by a diurnal motion, it would be necessary that very many animals, following the common motion of the Earth, should very frequently vary their declination and their speed in this motion. But this, by your own account, is an inconvenience. Therefore, etc. The MAJOR has already been shown, from the change of the parallels through which animals pass. Moreover, it would be necessary for the axis of the Earth to nod and swing this way and that with so great an inequality and anomaly that the appearance of the declination of the Fixed stars might be saved through it; but this inconstancy is no less an inconvenience than the variation of declination in the Fixed stars. Therefore not on this account either is the diurnal motion to be attributed to the Earth.

VII. Argumentum ab Inæqualitate Dierum Naturalium, orta ex motuum Diurnorum Inæqualitate.

VII. The Argument from the Inequality of the Natural Days, Arising from the Inequality of the Diurnal Motions.

XIX. Kepler hones a subtler argument in the *Epitome of Copernican Astronomy*, page 108, which I once pointed out in Book 3, chapter 32, numbers 2 and 3. In it, it is supposed — as in fact appears — that the individual diurnal motions are indeed equal to sense among themselves and in their parts, but, compared with other diurnal motions, are unequal: slower, namely, when the Sun is at apogee, and swifter when it is at perigee. With this supposed, Kepler argues thus: [Margin: Kepler's argument, acute but weak.] *If, with the Earth alone excepted, the whole remaining machine of the World sustained its own motion, no cause could be devised why the laws of this inequality, tempered to the motion of the single Solar sphere alone, should overflow into the whole machine. But if, with the machine of the world at rest, the earth rotates, the cause of this inequality is easily given: from the change of the interval between the Sun and the Earth in the same proportion, since the Sun is the minister and helper of all motion.* He points to the same cause at page 550 of the same *Epitome*. But we deny that no cause of the effect already mentioned can be given. For the cause is that Solar days are the measure commonly used in counting the motions of the other Planets, and therefore their inequality overflows into the motions of the others. And if the cause of the inequality already mentioned is the change of the interval, or distance, between the Sun and the Earth, it makes no difference in this respect whether the Earth itself is moved, approaching and receding towards the Sun — even if it is said to be stirred up by the Sun magnetically, or by a force spread through its light, when it is nearer, and not so stirred up when it is farther away — or whether the Sun approaches and recedes towards the Earth, and in approaching is objectively [obiectiuè] drawn by the Earth, for whose sake it is moved, so that it is then somewhat swifter, while in receding it is not so drawn.

CAPVT VII.

Chapter VII.

Proponuntur, & Diſſoluuntur Tria reliqua Argumenta pro Motu Diurno Terræ.

The Three Remaining Arguments for the Diurnal Motion of the Earth are Proposed and Resolved.

I. Argumentum à Cometis.

I. The Argument from Comets.

I. Seneca once raised the doubt, in Book 7 of the *Natural Questions*, chapter 2, whether Comets were carried along by the diurnal turning of the heaven and yet were not dissolved; or whether, rather, they were not dispersed so quickly for this reason, that it was not the heaven but the Earth that revolved by a diurnal rotation. [Margin: Seneca's uncertainty about the diurnal motion of Comets.] Let us repeat his words from there: *It will be useful to inquire whether Comets are of the same condition as the higher bodies. For they seem to have certain things in common with them: risings and settings, and even their very appearance, though they spread out and extend farther; for they are equally fiery and bright. Therefore, if all the stars are earthy, the same lot will be theirs too. But if they are nothing else than pure fire, and last for six months at a time, and neither the turning of the world nor its speed dissolves them, these too can consist even of thin matter, and not be shattered on that account by the constant circling of the heaven. To this question it will also belong to have examined whether, so that we may know it, the world goes round while the earth stands still, or the earth is turned while the world stands still. For there have been those who said that it is we whom the nature of things carries along without our knowing it, and that risings and settings come about not by the motion of the heaven, but that we ourselves rise and set. The matter is worthy of contemplation, so that we may know in what state of things we are: whether we have been allotted the most sluggish seat or the swiftest; whether God drives everything round us, or drives us.* So far that noble Philosopher. But it was long ago laid down by Aristotle and the other Peripatetics that the diurnal motion of Comets is to be attributed to the turning of the fire, or of the highest region of the air, carried off towards the West by the heaven. [Margin: Copernicus's opinion on the diurnal motion of Comets.] Copernicus, by contrast, in Book 1, chapter 8, ascribes to the Earth their apparent motion, by which they are seen after 24 hours to revolve to almost the same place; yet he denies that the air in which Comets are generated is carried along by the Earth's rotation. For let us repeat his words too: *Conversely, they say with no less wonder that the highest region of the air follows the celestial motion — the Peripatetics, that is — as those sudden stars indicate, the Comets, I mean, and those called Pogoniae [bearded stars] by the Greeks, for whose generation they assign this very place, and which, like the other stars too, rise and set.* So much from the opinion of others; then he adds from his own: *We can say that, because of its great distance from the earth, that part of the air is deprived of that terrestrial motion. Hence the air which is nearest the earth will appear tranquil,*

as will the things suspended in it, unless they are tossed to and fro, as happens, by wind or some other impulse.

[Margin: Gassendi's opinion on the diurnal motion of Comets, before he had heeded the sacred edicts.] II. From this, then, Gassendi hammered out an argument for the diurnal rotation of the Earth in Letter 2, *De motu impresso a motore translato*, judging it much more probable that Comets have no motion other than their own proper one, and that a wandering one, while the diurnal motion which appears in them comes from the turning of the earth. For he argues thus there, at page 110: *I note meanwhile, on account of the Comets: since, besides their proper trajections [traiectiones], which are now to the north, now to the south, now elsewhere, they also appear to be carried by the diurnal turning from rising to setting, what could be thought more probable than that they are moved by a single motion, that is, by their proper trajection, and that that carrying-round towards the setting is only apparent, from the diurnal turning of the Earth towards the rising? This turning, certainly, is of such a kind that, whatever is above or beyond the Earth — whether it exists, or is born, or passes through the spaces of the world — it ascribes to it, as also appears, a turning towards the Setting.* The whole argument of Gassendi, therefore, consists in greater verisimilitude, as he himself judges, and so it can be gathered into form.

[Margin: The argument reduced to form.] III. *If Comets have in reality no motion other than their proper trajection, the diurnal Motion which appears in them besides is to be attributed to the Earth. But it is more probable that Comets have in reality no motion other than their proper trajection. Therefore the diurnal motion which appears in them besides is to be attributed to the Earth.* The MAJOR is proved because that diurnal motion can no longer be attributed to the turning of the fire or of the air, since the heavens of the Planets are not solid, and therefore the sphere of fire, still less that of the air, cannot be carried round by the concave of the Moon. The MINOR is proved because there is no small difficulty in assigning the cause of so wandering a trajection; therefore we ought not to increase it by adding another real motion, which would render the agitation of Comets more entangled and of more uncertain cause.

[Margin: Reply to the 1st Argument.] The reply, however, is to grant the Major and deny the Minor and the consequence of its proof. For that is not more probable which is against the physical evidence acquired through the senses — of which kind is the diurnal motion of the Comets, just as of the other stars; and the cause that moves the Comets by the trajectory motion can at the same time move them by the diurnal motion, especially since it is most probably some Intelligence, as I taught in Book 8, Section 1, chapter 6, number 12. Just as, therefore, we do not take the diurnal motion away from the Planets, although they have a proper motion in longitude, latitude and altitude so varied and anomalous, because Intelligences lead them round towards the West along a spiral line, so neither ought we to withdraw it from the Comets; for in this respect everything appears in Comets just as in the other stars, as we saw a little earlier rightly asserted by Seneca. Nor do I see why an argument for the

motion of the Earth should be taken from the Comets more than from the Planets; for the greater difficulty in determining the moving cause of Comets arises not from the diurnal motion towards the Setting, but from the admirable variety of their proper trajection, and whatever cause of it is assigned, that same cause will be able, much more easily, to move them by the common, that is, the diurnal, motion.

II. Argumentum ab Auræ perpetuis intra Tropicos verſùs Occidentem flabris.

II. The Argument from the Perpetual Blasts of the Breeze within the Tropics towards the West.

IV. It is reported by ship-masters — as the Dutch relate, and Ramusius [Giovanni Battista Ramusio] in his history of voyages, but far more eloquently our own Iosephus Acosta [José de Acosta] in Book 2 of *De natura novi orbis*, chapter 10 and chapters 13 to 16 — that the Torrid Zone is highly habitable. This is not only because of the vast quantity of sea water, which does not reflect the Sun's rays as the land does from its plains, valleys and hills; nor only because of the shortness of the summer days and of the winter nights; but also, since God provides so gently, because of the frequency of summer vapours and rains, and above all because of the singular benefit of a most gentle breeze, whose coolness is so pleasant that some, with Ludovicus Vives [Juan Luis Vives] on Book 13 of *De civitate Dei*, chapter 21, have not unfittingly placed the earthly Paradise, or the land of Eden, under the Equinoctial. [Margin: For what reasons is the Torrid Zone habitable [?]] I shall note here the choicer points, so that the force of the argument proposed, and its solution, may shine out more clearly. In chapter 13, then, Father Acosta relates that in those regions within the Torrid Zone which are blown upon by a sea wind rather than a land wind, there is in a manner a perpetual spring, especially on the Peruvian sea: [Margin: The variety of the winds within the Tropics, and their admirable effects.] *on which we remember being cold when we first sailed it, and that at the time when the Sun bore down most directly, that is, near the Equinoctial, in the month of March,* says the same Author. Yet he admits that on the plains of great Ethiopia, of Brazil, of Paytiti and of Paraguay the winds are so hot that you would think them lit furnaces, and that certain seas within the Tropics are also oppressive with heat — namely the sea of Hormuz, that of Mozambique, the Brazilian and the Panamanian — but that in the same Clime many other seas have a most temperate air. So from the abundance and variety of these winds he accounts for certain admirable effects in that tract of the world: why the summer Sun, even at midday, is kept off there better by the lightest shade — a mat, say, or straw — than in Spain by tiled roofs; why the summer nights there are not hot; and why in the province of Collao there is cold even under a thin shade, although those living in the Sun close by suffer an intolerable heat. The Peruvian region, though full of sand and gravel, is nevertheless wonderfully temperate; again, the city of La Plata is

most temperate, most pleasant and extremely fruitful, whereas that of Potosí, although it too is mountainous, lies in the same climate and stands a very short distance away, is nevertheless squalid, very cold and barren. *All these varieties, therefore, are produced chiefly by the nature of the wind,* says Father José; *for where the supply of the gentler breeze is withdrawn, the heat of the Sun is so great that it burns amid the snows; where it is restored, all heat easily departs; and where this cold wind is familiar and, as it were, a resident, it in no way allows earthy exhalations to gather as from burnt matter — the one cause which in Europe makes the summer nights almost more oppressive than the days themselves, because the earth, scorched by the force of the Sun, gives off thick and smoky breaths, as if coming out of a furnace.* He adds that in Europe the pleasantest time in summer is the morning, and the most oppressive the afternoon; whereas in the Torrid Zone, especially in the Barlovento Islands, the chief heat is felt from earliest morning until about the tenth hour, sometimes to the point of sweating; then, around midday and afterwards, with the sea breathing on them, the rest of the day passes pleasantly, and towards midday the Euroaquilo, called there the Brisa, cools the sailors and the inhabitants.

[Margin: Iosephus Acosta's praise of the temperateness of the Torrid Zone.] V. Acosta goes on, in chapter 14, about the temperateness of the air found here and there within the Torrid Zone, and concludes: *As I contemplate this kindliness of what is, as it were, a perpetual spring — since neither does winter press with cold nor summer bake with heat, so that all harms are kept off well enough by a little turf, and there is scarcely any need to change one's clothes — it has truly often come to my mind that, if men were freed from the chains of greed and of perverse opinions, they would easily have lived a pleasant and blessed life here. For what the Poet either invents or relates of the Elysian Fields, what of Tempe, and what Plato of that Atlantis of his, they would certainly have found in these regions, had they resolved, with a free-born liberty, to rule rather than to be slaves to money.* Next, in chapter 15, he digresses into the causes of the winds; and although he touches on them from the teachings of Peripatetic philosophy, he nevertheless refers the chief one to God, who, as we have it from Psalm 134, brings forth the winds out of his treasuries, so that the Truth spoke most truly in John 3: *you hear its voice* — that is, of the wind and of the spirit — *and you do not know where it comes from, or where it goes.* For it is hard to explain why along the whole sea-coast of Peru, over very long stretches, only one wind blows; and why the same South wind, which is most pleasant with them on this side of the Equator, becomes heavy and murky as soon as the Equator is crossed; why the North wind there gathers clouds and wrings them out into rain, and is held to be sluggish; why the Barlovento islands are cooled by perpetual North winds that bring abundant rain, while the South wind or the Africus can scarcely gain access there; why the region of Brazil before the promontory of St Augustine is perpetually beset by land winds, while that of Peru, in the same climate, is always blown upon by sea winds, and most pleasant ones. At the end of the chapter he notes what might be the cause of these varieties: namely that the torrid Zone is either full

of very high mountains, or for the most part interspersed with or surrounded by the Ocean, from which the winds are somewhat cold and rather subtle.

VI. Finally, in chapter 16, from the record of nautical observation, he affirms that within the Tropics, on either side, and especially on the high Ocean, winds blowing from the East and North prevail perpetually, while those from the West and South are rare and almost none; from which he concludes, rightly and no less elegantly, that this is the cause of so different a navigation. *For it is not the case,* says Acosta, *that, as the road from Thebes to Athens and from Athens to Thebes is the same, so is that from Spain to the Indies and from the Indies to Spain. The coming is indeed downhill, and — if I may play the poet — easy is the descent to the Indies; but to retrace one's step and escape back to the old world, that is no easy labour.* The cause, he says, is that fleets sailing from Spain to the West Indies enjoy almost perpetual favourable Euro-Aquilo winds, but those returning from there have the same winds against them; to escape these, they sail out beyond the Tropics to the degrees of a higher heaven, so as to find, on the way back, South or South-west winds that serve them — but by a longer course than before. [Margin: Routes to the Indies and from the Indies.] For the usual route to the West Indies and New Spain from the Fortunate Isles is almost straight; but the return is from New Carthage by way of Havana, the port of Cuba, and from there to within sight of Florida, past the ill-fortune of Bermuda, Terceira, and near the sacred promontory of St Vincent. Likewise, from New Spain and Peru across the Pacific to the Solomon islands the passage is easy and the return difficult, unless a West wind is sought beyond the Equinoctial and the Tropic of Cancer towards the shores of New Spain, or unless, once the Tropic of Capricorn is passed, you turn towards the region of Chile. In the same way, from Mexico to China and the Philippine islands the voyage is short and quick, and the return voyage slow and arduous. He admits, however, that this general law has its exceptions in places; for in the maritime region of the Southern Ocean, although it lies within the Tropics, the South wind prevails for almost the whole year. [Margin: Robert Dudley's testimony on the Winds within the Tropics.] Robert Dudley, Duke of Northumberland, says no differently in his *Arcana maritima*, recently published in Italian: for in Book 2, chapter 20, he says that within the Tropics there are fixed, that is, perpetual, winds from the East — as much from Africa towards the Americas, and from the Americas towards the Moluccas and the Philippines, as from there towards Africa — and that they usually blow with a uniform tenor and are healthy; so much so that, on the return from the East Indies towards the island of St Helena, the return is almost twice as short as the voyage from there to those Indies had been; and finally that it is a sure rule that those who sail according to the diurnal motion mostly enjoy favourable, healthy and fair winds, etc. These things have perhaps been told at too great length; but they were told so that, from the very narrative of so religious and experienced a man as we know Acosta to have been, the fiction of Galileo and Gassendi may at once collapse.

[Margin: Galileo's opinion on the apparent motion of the air towards the West.] VII. For Galileo, in Dialogue 4 on the System of the World, page 327 of the Latin edition, saw it to follow that within the Tropics, and on the open plains of the Ocean, where there is a smaller supply of thicker vapours, the air would not obey so readily the carrying-off by the terrestrial rotation, and therefore, by resisting that rotation as it revolves towards the East, would make a perpetual wind towards the West, or the appearance of a wind, which would be more perceptible where the rotation of the terrestrial globe is swifter, namely around the Equator. Seeing this, he does not hesitate to confirm the diurnal motion of the Earth from the perpetual winds which those sailing from the Mexican port across the Pacific to the East Indies, etc., experience. To this experiment Sagredo subscribes in the same place, affirming that in the Mediterranean too, unless accidental and transverse winds stand in the way, one sails back from Syria to Italy more quickly than from here to Syria — indeed almost four times as quickly. Salviati, however, not undeservedly refers this also to the waters running towards the Strait of Hercules, granted that in the Strait of Sicily the water runs eastward along one shore and westward along the other. [Margin: Gassendi's support for the same motion.] Gassendi too, in Letter 2, *De motu impresso*, page 92, having asserted that the air near the earth is carried along by the diurnal rolling of the Earth, nevertheless added that, because of its fluidity, it does not follow the earth so closely as not to be retarded somewhat towards the western parts: *They say,* he states there, *that this is evident not so much in valleys, within which the air is confined on either side and is not free, as on plains and open fields, where little vanes are observed, whenever calm prevails, to be turned towards the West; but that it is evident most of all at sea, and above all under the Equator itself, where the sails of ships are filled steadily and uniformly from the East; and that for this reason sailors find that they cover the same course both far more easily and in a shorter time towards the West than towards the East.* From this, then, Galileo and Gassendi confirm the rotation of the Earth, because, once it is asserted, a readier cause is to hand for that perpetual and uniform wind within the Tropics; and from these points one may argue thus.

[Margin: Argument 2 in Form.] VIII. *If a perpetual and uniform Wind blew towards the West within the Tropics, it would be a very probable sign of the diurnal revolution by which the Earth was turned towards the East. But it is established by experience that a Wind of this kind blows within the Tropics. Therefore it is a sign of the diurnal revolution by which the Earth is turned towards the East.* The MINOR seems already proved from the historical testimony of the ship-masters. The MAJOR, too, is firmly enough established by Galileo and Gassendi; for no other, more probable, cause can be adduced why such a wind should be felt perpetually within the Tropics rather than elsewhere, and towards the West rather than in another direction, except that the air in that open tract, being very little entangled with watery and earthy vapours, neither moves of itself with the motion of the earth and the water, since it is not of their nature, nor is carried at all towards the East by their rotation, because its thinness and fluidity

make it unfit to take on so great an impetus; and therefore, by forsaking, or not following, that motion, it behaves just as if it were moved towards the West.

[Margin: 1st Reply.] The reply, first, is to deny the Major. For it would not be a convertible sign of such a motion — granted that, if such a motion of the Earth were posited, it could very probably be adduced as at least a partial cause of such a wind, provided the wind were perceptible universally within the Tropics, and in the neighbouring Climes as well, where plains and seas spread out more widely. For it is no more a sign of the Earth going towards the East than of the Sun, which by its diurnal motion, with the whole chorus of the stars, towards the West, leads round with itself the vapours and exhalations it has raised, or successively raises one after another towards the quarter into which it is carried; or, again, of the sea waters, which are known to run towards the West, as a cause assisting the generation and motion of that breeze. For it is evident that all the waters of rivers, torrents and canals draw with them some breeze or other, a little wind, in the direction in which they themselves run down. And so the ship-masters, as we saw from Dudley, credit the benefit of that wind to the diurnal motion of the Sun. And it is certainly admitted among the Meteorologists that winds are raised mostly, and stronger, when the Sun is rising or about to rise, and more often from the Eastern quarter than from the Western; and that on the broad plains of the Ocean they are more uniform, for this reason: that there is no inequality there of mountains, valleys, woods and cities, which usually supplies the matter of unequal winds — as Descartes in particular teaches, briefly but lucidly, in his *Meteors*, chapter 4, marginal numbers 3, 4, 12 and 13.

[Margin: 2nd Reply.] I reply, second, by denying the Minor taken universally, or with those conditions which are required for such a wind to be an effect and sign of the terrestrial rotation. For neither does a wind of this kind blow in all the seas or plains within the Torrid Zone, however widely open, nor, where it does blow, does it blow directly from the eastern quarter, but mostly from a lateral quarter lying between the Solanus and the Aquilo, or else between the Solanus and the Auster; and the Euroaquilos are the more frequent; nor do they keep the same tenor all day, but vary perceptibly with the rising and the afternoon Sun, as we have already seen from Father Acosta's history.

III. Argumentum à Terræ Chymicæ & Terrellæ Magneticæ ſimilitudine. Vbi obiter quædam inſignia experimenta magnetica ope Terrellæ facta.

III. The Argument from the Likeness of the Chymical Earth and the Magnetic Terrella; where, in passing, certain notable magnetic experiments made with the help of the Terrella.

[Margin: The Chymical Earth.] IX. Iacobus Lansbergius [Jacob van Lansbergen], in the *Apologia* for Philips van Lansbergen on the motion of the Earth, chapter 5, adduces this argument as his eighth, and says: "The Physical Earth

of the Chymists (which is not a magnet, as Froidmont thought in his *Vesta*) is moved from West to East; therefore so too is the whole Earth, of which it is the image." Georgius Polaccus replies in his *Anticopernicus*, assertion 176, that this Hermetic Earth is to be left to the Paracelsians and the Fluddists, and that from its motion the motion of the whole Earth is not adequately argued. For my part, I have not yet been able to see this experiment. But granting it, we deny the consequence, in the same way as from the rectilinear downward motion of a ball of clay, or of a clod of earth let fall, one may not infer the downward motion of the whole Earth. Setting this aside, therefore, let us come to the argument taken from the Magnetic Terrella.

[Margin: What a Terrella is.] X. A Terrella — that is, a Magnetic one — is nothing other than a small sphere fashioned on the lathe from the Magnet stone; or it is a globular Magnet, customarily formed so by art, because this figure is the fittest of all for undertaking various magnetic experiments. So teach William Gilbert, in Book 1 of *De magnete*, chapter 3, and Book 6, chapter 1 — he gives experiments of this kind in Book 1, chapter 4; Book 2, chapter 27; Book 3, chapters 4, 7, 8, 9, 17; Book 4, chapter 2; Book 6, chapter 4 — and Father Niccolò Cabeo, in the *Philosophia Magnetica*, Book 1, chapters 5, 17, 18, 22, 24; Book 2, chapters 10, 11, 15; Book 3, chapters 4, 12, 16, 17, 19, 21, 34, 37; and Book 4, chapters 9, 11, 17, 36, 37, 39, 40, 41, 45. For in all these places experiments made with the help of the Terrella are explained. From them we shall select three or four, so that the reasoning of this argument may become clearer, first setting out the following diagram, in which let AZBN be the Meridian, and in it A the South Pole of the World and B the North, Z the Zenith and N the Nadir. Then let there be made, from the best Magnet obtainable — an Arabian one, say — a sphere as round as possible, CbDa, which from now on is to be called the Terrella.

Diagram. A large circle, the meridian, encloses a smaller hatched circle, the Terrella, whose centre lies a little below that of the large circle. A thread hangs from the top of the large circle to the top of the Terrella. Small arrows, each marked with a cross and a dot, stand at various points between the two circles and at the top and foot of the Terrella. Inside the Terrella a dotted vertical line carries R above and P below, and a dotted horizontal line runs from a to the point opposite it.

- [?] (head of the thread, top of the large circle): a curled sort, unread
- A (left, outside the large circle): South Pole of the World
- B (right, outside the large circle): North Pole of the World
- N (foot of the large circle): Nadir
- E (upper left, between the circles)
- F (upper right, between the circles)
- K (left, between the circles)
- M (left, between the circles)
- I (lower left, between the circles)
- H (foot left, between the circles)

- G (lower right, between the circles)
- S (right, between the circles)
- c or e [?] (top of the Terrella)
- R (inside the Terrella, upper)
- P (inside the Terrella, lower)
- D (foot of the Terrella)
- a (left of the Terrella)
- b or 6 [?] (right of the Terrella)

[Margin: Investigation of the Poles of the Terrella.] Since every Magnet has two faces, one southern and the other northern, one must first investigate in this Terrella each of these faces, that is, its poles. This is not done by suspending it from the thread ZC and noting which part it turns, by its own turning, towards the South and which towards the North, as if the points a and b were to be taken for the Poles of the Terrella. [Margin: 1st Experiment.] For, as Cabeo observes in Book 5, chapter 5, from this one concludes only that the south pole of the Terrella is in the hemisphere CaD, and the north pole in CbD; and it can happen that the former is at F or at G, and the latter at H or at E, because the point C, from which the Terrella was suspended, is not a full quadrant distant from its Poles, but less than a quadrant — 45 degrees, say. [Margin: 2nd Experiment.] A surer method, therefore, is if small bits of a rather fine iron wire, scarcely longer than a barley grain, you bring them up to various points of the Terrella. For where they adhere to the Terrella most straightly and perpendicularly, know that its poles are there; and where they touch the Terrella with equal balance and inclination on both sides, those points will be a full quadrant of a circle distant from the poles. [Margin: 3rd Experiment.] Another method, which Cabeo suggests in the same chapter 5, is of this kind. Apply a versorium, that is, a magnetic needle, on a pivot that can be carried round over the Terrella, to different parts of the Terrella's surface, until at some point it obtains a most exact equilibrium, as at C — that is, it inclines towards the Terrella no more with its point than with its little cross, but makes equal angles on both sides with its periphery. By the same device search out several other points, say R, P, D; for when a circumference is drawn through them, you will have the Equator of the Terrella, which is equidistant from either Pole. So, with one leg of a pair of compasses fixed at any one point of the circle CRPD, you will be able to describe with the other leg, bent, some meridian of the Terrella — say aCbD; for in it the points a and b, marked off at a quadrant's distance from the Equator, will be the Poles of the Terrella. Then, if you suspend the Terrella from C, a point of the Equator, by a thread twisted as little as possible, it will turn itself towards the poles of the World in such a way that with its north pole b it faces the North pole of the World, B, and with its south pole a it looks towards the South Pole of the World, A; and the axis of magnetic direction will be ba — keeping, however, as to its situation with respect to the Meridian, the declination from the Meridian which the place where you live requires, and which magnetic needles keep in any case.

And so, if the experiment is made at Bologna, the axis ba of the Terrella will decline towards the East by 3½°, and elsewhere otherwise, according to what was said in Book 2, chapter 18. When versoria, or needles, are applied to other points, say to E, F, G, H, you will see them incline more towards the Terrella with the point or with the little cross, as the magnetic face and the poles of the Terrella require; and at I and K the points will converge towards the pole a, while the little crosses, turning away from each other, will diverge. [Margin: 4th Experiment.] But what bears most on our subject is this: if you enclose the Terrella in a wooden box or a little cork net, and set the box on the water of a broad vessel so that it can float and turn freely; and close the room or chamber so that no wind can get in, and keep iron tools far away; you will see, not very long afterwards, the Terrella, by its own turning, come to rest at last in the situation befitting it, so that it faces with the pole b the North pole B, and with its pole a the South pole A, and rests there, with the axis ab raised towards the pole visible to you by about as much as the altitude of your pole requires. If you lived under the Equator, however, that axis would be parallel to the horizontal plane AB.

From this, then, Gilbert concludes in Book 6 of *De magnete*, chapter 4, that just as the Terrella has a natural faculty for circular motion about its own centre, by which it turns itself in the plane of the horizon with its poles to the poles of the World, so the whole earth, which in the same book he contends is a great Magnet, has a natural power for circular motion about its own centre; so much so that if it were pulled away from its situation, and its north pole were twisted elsewhere by some force, it would run back to its former situation by a natural rotation. He adds in chapter 6 that all terrestrial things, although separated from the earth, are nevertheless drawn round by it through magnetic effluvia, just as he thinks that the parts of each primary globe — the Sun, say, the Moon and the other Planets — would be drawn by them if they were separated from them. [Margin: The argument in form.] With these things posited, he seems to argue in this form: *The whole Earth stands with regard to the motion of rotation about its own centre as the Terrella stands with regard to the motion of rotation about its own centre. But the Terrella is moved circularly about its own centre; therefore the Earth too is moved about its own centre; therefore also by the diurnal motion.*

Someone might reply by denying the Major, on the ground that the Earth is not (as Gilbert contends it is, in Book 6 and elsewhere) a great magnet, or of the same lowest species as the magnet. For our Cabeo refuted this excellently in Book 1 of the *Philosophia Magnetica*, chapter 19, with many arguments indeed, but above all with this one: that if the Earth were a perfect magnet, it would snatch iron to itself from a far greater distance, in proportion to its bulk, than the tiny magnetic Terrella snatches a needle. But let us grant the Major for the time being.

[Margin: 1st Reply.] The reply, however, first, is this: granting the Major, we distinguish the Minor and the first Consequent, conceding the Minor and the Consequence if the Terrella and the Earth are moved out of their situation,

and denying them if they remain in their natural situation, which the axis requires; but we deny the second Consequence, for more is inferred than can be inferred from the premised propositions. For the Terrella has no rotation at all about its poles towards the East, even if it is suspended on its poles in the Meridian, whatever Petrus Peregrinus [Pierre de Maricourt] may have invented — whom Gilbert himself, in Book 6, chapter 4, not to mention Cabeo in Book 3, chapter 4, rejects, as we shall shortly see. Nor could it be proved to Father Athanasius Kircher or to Father Nicolaus Zucchius [Niccolò Zucchi], most learned writers on the Magnet, since they rather confirm the immobility of the Earth from the Earth's magnetism.

[Margin: 2nd Reply.] The reply, second, therefore, is to retort the argument: *The whole Earth stands with regard to motion and rest as the Terrella does. But the Terrella, as long as it is in its natural situation, is not moved; and when it is in an unnatural situation, it is not moved towards the East about its axis, but by another motion, one that turns the axis to the poles of the world. Therefore the whole Earth too, as long as it is in its natural situation, is not moved; and if it were in an unnatural situation, it would not be moved towards the East, but by another motion, etc.* Now it is established from the tradition of all the centuries in which observations of polar altitudes have been held that the Earth has been in its natural situation, and has always faced the poles of the world directly with the axis of its Equator. Therefore the Earth has always rested immobile, as it rests now too. The Major is already assumed by Gilbert, and urged by certain experiments in Book 1, the last chapter: namely, that the Earth has a magnetic virtue, by force of which it directs itself to the poles of the World, or keeps that direction acquired once from the beginning of the world. [Margin: Niccolò Cabeo's and Zucchi's arguments for the magnetic force of the Earth.] And it is further proved by Cabeo, in Book 1 of the *Philosophia Magnetica*, chapters 17 and 18, and by Father Niccolò Zucchi in his *Nova de machinis philosophia*, part 5, section 3. First, because it has been observed that the veins of earth and of stone which are seen on the sides of mountains after floods run out parallel to the axis of the world — which Kepler testifies was observed in Germany too — and meet the horizon, to sense, at an angle as great as the altitude of the pole. Next, the Earth communicates magnetic force to iron tools, as Gilbert tries to show in Book 3, chapter 12, but Cabeo shows by firmer experiments in Book 1, chapter 17. Now no one gives what he does not have; therefore the Earth has a magnetic virtue, which it communicates to iron tools — so much so that the bars of iron gratings drawn out of very old windows attract with their upper part the north point of a versorium, and with their lower part the southern little cross, in our regions, where the North pole is elevated; and they attract from a distance of four ells and more, which no magnet, however strong, can achieve. Again, if you bring a dagger or a sword, held by the hilt perpendicular to the horizon, up to a versorium or magnetic needle, the part that hangs over the versorium attracts the southern part of the versorium; and if you bring the same sword up to it from below, under the versorium, in a perpendicular ascent, the point of

the sword attracts the northern part of the versorium. Then, in chapter 18, he teaches that this magnetic force was given to the whole terrestrial globe so that it should keep itself in its situation towards the poles of the world, and could not be moved about its centre either by the force of winds or by a change of its centre of gravity. From this, too, the immobility of the Earth is confirmed.

[Margin: Petrus Peregrinus's fiction about the diurnal rotation of the Terrella.] XI. But since Petrus Peregrinus, as Gilbert reports in Book 6, chapter 4, steadfastly affirms that the Terrella, suspended on its poles in the Meridian, is moved circularly in a complete revolution of 24 hours, let us hear what those most experienced in magnetic matters think of this. And first, Gilbert adds in the same place: *This, however, it has not yet been our lot to see; and we doubt this motion too, on account of the weight of the stone itself; and also because the whole earth, as it is moved by itself, so is it also moved on by the other stars — which does not happen proportionally in any part, as in the Terrella. The earth is moved by its own primary form and by natural desire, for the conservation, perfection and adornment of its parts.*

[Margin: Cabeo's teaching on the motion of the Terrella and of the Magnet.] But Cabeo, in Book 3, chapter 4, teaches that a magnet, and therefore a Terrella, has no power of directing itself to any parts other than the polar ones, and has no eastern or western face; and this both a posteriori and a priori. A posteriori, indeed: because if you set a magnetic globe, exquisitely round, on its poles, found as described above, so that it can be turned very easily, and place its axis parallel to the axis of the earth; or insert it in two circles, in almost the same way as a nautical compass box is usually enclosed in bronze circles, so that, whatever the motion of the ship, the box stays parallel to its plane of the horizon; and set it, so inserted, magnetically, that is, by directing its axis to the poles of the Earth, and parallel to the axis of the Earth, it will never be moved towards any other quarter of the sky, except as far as the magnetic declination in that place requires; which is a sign that the Terrella neither regards nor loves any but the polar points. [Margin: The magnet regards not the heavens but the poles of the Earth.] A priori, moreover: because the Magnet does not, properly speaking, regard the heavens or points of the heavens — neither Ursa Minor, as Marsilius Ficinus thought; nor other stars, as Paracelsus did; nor the rising of a star in the tail of Ursa Major, as Gauricus [Luca Gaurico] and Cardano did; nor the Pole of the Zodiac, as Bessardus the Frenchman [Toussaint de Bessard] did; nor a point near the pole of the world, as the Conimbricenses and Martinus Cortesius [Martín Cortés] did — but the poles of the Earth, as Robert Norman, a most skilled sailor and an ingenious craftsman, first observed. Cabeo, too, in Book 1, chapter 15, Zucchi in the place cited above, and Athanasius Kircher in Book 1 of his *Magnes* confirm this by experiments. For if you hang by an untwisted silk thread a very thin little plate of steel, perfectly straight, eight or ten fingers in length and pierced in the middle, and excite it magnetically — that is, touch one end of the little plate with one face of a magnet and the other end with the other — you will see that the part which faces the northern hemisphere (if

you live in some northern climate) is not raised upwards so as to regard the North pole, or any part near this pole, but is depressed downwards towards the earth, and the more so the higher the pole stands in that climate; and that the other end is raised, so that it cuts the axis of the world crosswise. Lest you think that this comes from a less than exact equilibrium, destroy the magnetic virtue by a contrary touch — that is, touch with the north face the end of the little plate that you had touched with the south face, etc. — and you will see the end which was depressed before raised, and the other, which was raised, depressed. The same is proved by another experiment, from Gilbert's Book 5, chapter 9, and Cabeo's Book 3, chapter 4: namely, if you pass a straight iron wire through a little cork sphere, equally on either side, and set it on still water, sheltered from every breath of air, so that it sinks below the surface of the water but not to the bottom, and can turn itself freely — but before you put the wire in the water, its ends must be rubbed with a magnet. When this is done, you will see the wire decline towards the earth below the plane of the horizon with its north end, and indeed by almost as much as the altitude of the Pole is in that place. Again, magnetic needles brought up to a Terrella direct themselves to the poles of the Terrella; therefore they do not look to the poles of the world, or to the stars. Lastly, see the instrument which, invented by Gilbert in Book 5, Cabeo perfected in Book 1, chapter 20, and Kircher reported in Book 1 of the *Magnes*: for it teaches a way of suspending a very long magnetic needle in most exact equilibrium, so that, inside a vessel covered with a glass hemisphere, one may observe its motion, and by how many degrees, marked on the semicircle of the bowl, or lower hemisphere, it descends with its north point below the horizon. Granted that the measure of these inclinations which Gilbert assessed does not answer to the observations made by experts beyond the Equator, as Kircher testifies in his *Magnes*, Book 1, part 2, and Zucchi in part 5 of the *philosophia de machinis*, section 8. Since these things are so, and it is sufficiently plain from this that magnetic bodies do not regard or love the poles of the heavens of themselves and immediately, but rather the poles of the Earth, while the Earth itself so regards the poles of the world that, being spherical and homogeneous, it has no part of itself which is absolutely eastern or western — for the same part, say the land of Rome, which is eastern to the Mexicans, is nevertheless western to the people of Goa (which cannot be said of parts situated under the same Meridian, for some of them are absolutely northern and on this side of the Equator) — it follows, says Cabeo in Book 3, chapter 4, that the whole earth has no power of directing or moving itself to other points of the heavens than to the poles of the world.

[Margin: Athanasius Kircher's opinion on the Earth's motion impeded by magnetism.] XII. Further, Athanasius Kircher too, in Book 1 of his *Magnes*, part 2, from page 53, teaches that circular motion is more repugnant to the Earth than straight motion; for gravity alone impedes straight motion upwards or downwards, but by magnetism the Earth is directed along the axis of the world — so much so that even if there were a mountain as high as the Earth's

diameter, it still could not be moved from its situation by a driving wind. And in Book 2, part 5, he teaches that the itch to establish the Copernican motion is intolerable, for by force of it occasions for urging that motion are begged from every quarter out of uncertain and slippery experiments. However, Father Niccolò Zucchi, [Margin: Zucchi's opinion on the magnetism of the Earth.] in his *Nova de machinis philosophia*, part 5, section 10, does indeed reject the motion of the Earth, but nevertheless asserts that the magnetic force in the globe of the Earth is not there to impede the diurnal rotation about its axis, because the direction of the axis to the poles of the world can stand and that motion nevertheless be carried out. Next he mentions a certain new experiment, made by some investigator of nature or other, by which it is proved that a Magnet turns and settles itself, according to its own determinate plane, in the Meridian of any region whatever, if it is set up through its axis in a vertical line so that the one pole of the magnet which usually turns to the North is raised upwards; for then certainly those parts of it turn to the West which, when that same pole was turned downwards, always stood towards the East. He gives the reason for this there and in section 6: from the refraction of the magnetic rays diffused from the poles of the Earth to the mass from which the Magnet was formed — a refraction that was then made in the plane of the stone congruent with the meridian of the Earth, precisely along up and down, and not of itself from the magnetic force. But consult the Author yourself. Meanwhile it is sufficiently clear that this very motion, too, is not made from West to East upon the axis of the Equator, in the Equator of the Magnet itself. Therefore the diurnal conversion of the earth has not yet been proved by any magnetic experiments.

XIII. So much for the arguments which it seems can be devised for the diurnal revolution of the Earth about its axis and centre. For what Galileo sought out from the flux and reflux of the sea pertains not only to establishing the diurnal motion but to establishing other motions of the Earth as well, and will therefore have to be examined below in a separate chapter.

CAPVT VIII.

Chapter 8.

Propon[?]ntur & Diſſoluuntur Argumenta Decem pro Tellure extra centrum Mundi per Annuum motum collocanda, ex Conditionibus varijs Telluris & Planetarum, motum non inuoluentibus.

Ten Arguments for placing the Earth outside the centre of the World by an Annual motion, taken from various Conditions of the Earth and the Planets that do not involve motion, are proposed [?] and resolved.

[Margin: The order of examining the arguments for the annual motion of the Earth.] I. All the arguments which have been devised with most subtle

inquiry by the Philolaics and the Copernicans for removing the Earth, if it could be done, from the centre of the universe, and for carrying it about that centre in an annual orb, seem reducible to four general heads: namely, either to certain conditions of the Earth compared with the conditions of the Planets, but not yet involving motion; or to the motion of the Planets itself; or to other motions observed in the heavens; or, finally, to motions or changes observed in the sphere of the elements. We too, therefore, shall keep this order in weighing them.

I. Argumentum à Nobilitate Solis maiori quàm Telluris.

1. The argument from the nobility of the Sun, greater than that of the Earth.

II. There seems to be no doubt that the centre of the Universe is the noblest place in the world, since it is equally distant on every side from the extremes and holds the middle situation. Hence it came about that certain Pythagoreans, as Aristotle reports in *De caelo* 2, texts 72 and 73, placed in the middle of the Universe not the Earth but Fire, in order to assign the most honourable seat to the most worthy of bodies; and this Fire they called the guard, or prison, of Jupiter. That the chief author of this opinion and argument was Philolaus we have already learned from Plutarch, *De placitis* Book 3, chapters 11 and 13, and we have already reported his words in chapter 3 of this section, where, from number 3 on, we also treated of Vesta, placed by the ancients in the centre of the World as a terrestrial Fire. [Margin: The argument of Philolaus and Kepler.] This Fire, however, the Copernicans assert to be the Sun — above all Kepler, in Book 4 of the *Epitome of Copernican Astronomy*, page

444: for, they say, the Pythagoreans were accustomed in this way to conceal their doctrines under other words, and by Fire to have meant the Sun, as the most excellent of all bodies and the one to which the most fitting place is owed for guarding and preserving it; and this place, they say, is the centre of the Universe. Aristotle had tried to blunt this argument of the Pythagoreans, saying that the middle of magnitude and the middle of the nature of the thing are not the same in a cosmic body — just as in animals the principle of life, which is the heart, is not precisely in the middle of the animate body, if you look to the middle of magnitude, but in another, more fitting place — and that one must therefore seek elsewhere than from the centre of the bulk of the universe itself which place is more fitting for that principle on which the chief operations of the universe depend. To this Kepler says, in that place, that the case of animals, whose bodies are not round, is unlike that of the World, which is spherical and needs no operation outside itself; so that there is no reason why its heart should not be in the centre of the universe. He adds that Aristotle, in looking for baseness in the centre, does not do rightly, since the centre is the principle of a likeness that foreshadows the mystery of the Trinity: for by the centre the first person, the origin of the others, is designated. Oh, how many mysteries to

dress up this most impoverished argument! Reduced to the form of a syllogism, it is as follows.

[Margin: 1st Argument in form.] III. *To the most excellent of the cosmic bodies the most excellent place is owed. But the Sun, and not the Earth, is the most excellent body of the world, and the most excellent place of the Universe is the centre; therefore the centre of the Universe is owed to the Sun, not to the Earth.*

[Margin: Reply.] The reply is made by conceding the Major, of a place most excellent not by mere Geometric excellence but by the physical end and good which such a body ought to receive from others, or to communicate to others. But in this sense the latter part of the minor proposition is conceded, with regard to the natural end, of which we are speaking here; but the former part is denied. For the Earth ought not to be taken barely as a mere element, one of four or of three elements, but together with the living plants and the animals, and above all with men, for whose sake all the stars were made and are moved, as God attests in Deuteronomy; and taken thus it is the most excellent of all the bodies of the world, if, as is fitting, we value the greatness of its virtue and the dignity of its end rather than the greatness of its bulk. I said "speaking of the natural order and end": for if we speak of the supernatural, the centre of the Earth is the lowest and most wretched place, and the place of the prison of Hell, which is no longer the guard of Jupiter, nor of a saving Fire, but of the Fire destined for the eternal burning of the damned; whereas, on the contrary, the Empyrean — that is, the earth translated into heaven, or the Land of the living — is the most excellent place.

II. Argumentum à Centro Syſtematis Planetarij.

2. The argument from the centre of the Planetary System.

[Margin: 1st Reason of Copernicus for the centre of the Planetary System.] IV. The Copernicans have affirmed, for two causes chiefly, that the centre of the system of the Planets is not the Earth but the Sun. The first Copernicus touched on in Book 1, chapter 5, in these words: *For if anyone should deny that the earth holds the middle or centre of the world, and yet not admit that the distance is so great as to be comparable to the sphere of the non-wandering stars, but notable and evident with respect to the orbs of the Sun and the other stars; and should think that for this reason their motion appears varied, as though they were regulated about another centre than the centre of the earth — he could perhaps offer a not inept reason for the varied apparent motion. For the fact that the wandering stars are seen nearer to the earth, and the same ones farther away, necessarily argues that the centre of the earth is not the centre of their circles. Still less is it established whether the earth nods towards them and away from them, or they towards the earth and away from it.* Hence Galileo, in Dialogue 3 of the *System of the World*, page 241 of the Latin, when Simplicio asks how it is established that the Sun is in the centre of the revolution of the Planets, answers in the person of Salviati that this is made out by most evident and necessary observations. The first of these is that all the

Planets are found now nearer to the earth, now farther from it, by differences so enormous that Venus, at its most remote in its apogee, is found to be six times farther from us than when it is nearest and perigee; and Mars, when apogee, has a distance from the earth eight times greater than when perigee. This argument, however, he says, does not hold of the Moon, because it is established on other grounds that the Moon cannot be separated from the earth as the centre of its motion.

V. The same Copernicus brought forward the second reason in Book 1, chapter 10: namely, that the five lesser Planets complete their circuits about the Sun. Let us hear him, so that we may draw more clearly from the very source of this doctrine. [Margin: 2nd Reason of Copernicus.] *Therefore,* he says, *I think that what Martianus Capella, who wrote an Encyclopaedia, and certain other Latins knew well is by no means to be despised. For they think that Venus and Mercury run round the Sun, which exists in the middle, etc.* And shortly after: *What else, then, do they mean to signify than that the centre of those orbs is about the Sun? Thus indeed the orb of Mercury will be enclosed within that of Venus, which must be twice as large and more, and will obtain within that amplitude a place sufficient for itself. If anyone, taking occasion from this, should refer Saturn too, and Jupiter and Mars, to that very centre — provided he understands the size of their orbs to be so great that, together with them, it contains and surrounds even the earth abiding within — he will not err, as the canonical reckoning of their motions declares.* And he at once confirms this, saying: *For it is established that they are always nearer to the earth about their evening rising, that is, when they are opposed to the Sun, with the earth between them and the Sun; but most remote from the earth at their evening setting, when they are hidden about the Sun, namely when we have the Sun between them and the earth. These things indicate sufficiently that their centre belongs rather to the Sun, and is the same as that to which Venus and Mercury too refer their revolutions.* Galileo pursues exactly the same reasoning in Dialogue 3 of the *System of the World*, likewise page 241, and Kepler in Book 4 of the *Epitome of Copernican Astronomy*, page 536. But what Copernicus had assumed about Venus and Mercury on the mere authority of Capella and of certain Latins, Galileo himself affirms much more certainly by the experiment of the Telescope, by which it is now established that these Planets are illuminated by the Sun just as Moons going round it are. By these conjectures, then, partly, and partly by certain observations, both these men and the other Copernicans — above all Rheticus in his *Narratio prima*, and Kepler in the introduction to the *Commentaries on Mars* and in the *Epitome of Astronomy*, page 450 (who had nevertheless rightly advised, on page 449, that Copernicus's hypothesis is not disturbed if the Sun, rather than the centre of the great orb, is placed as the centre of the Universe) — try to persuade, and as it were to demonstrate, that the Sun is in the centre of the world; that it was therefore deservedly called by the Ancients [Greek: χορηγὸν (chorēgon, "leader of the chorus")], that is, the Choragus of the Planets and the moderator of Nature; and that those praises of the Sun are no more Poetic than Physical. Now, then, to the argument.

[Margin: 2nd Argument in Form.] VI. *That body ought to be in the centre of the Universe which is the centre of the System of the Planets; but the centre of the Planetary System is not the Earth but the Sun: therefore not the Earth but the Sun ought to be in the centre of the Universe.* The MAJOR is not indeed proved by the Copernicans, but rather supposed, as though it were certain that the other Planets are moved about the centre of the world, on the ground that the system of the Planets seems the chief part of the system of the world. The MINOR has already been proved at numbers 4 and 5, from the notable variety in the distance of the lesser Planets from the Earth, and from the circuit of Venus and Mercury about the Sun, from which the same becomes very probable of the three remaining Planets.

[Margin: 1st Reply.] I reply by distinguishing the Major, and denying it if that body is not the centre of the whole Planetary System taken adequately, nor of the Fixed stars, nor of the new Phenomena, nor of the elementary motions and of the animals living in them; for all these, just as they are to be considered for the integrity of the Universe, so too are they to be considered for constituting its centre, inasmuch as the centre includes a relation to all, and not only to some, of the great parts of the world. But if it is such a body, I concede the Major; and in this sense I deny the Minor. For granted that it is now certain, against Ptolemy, that the Sun is the centre about which Venus and Mercury revolve, and that, according to Tycho, the Sun is the Choragus of the five lesser Planets, which describe their orbs around it; it is nevertheless not the centre of the Lunar motion, nor of the motion of the Fixed stars, nor of the new stars, nor of the Comets, nor of the Elementary motions. Indeed, according to our system, which can probably be maintained with the phenomena saved, it is the centre only of the circulations of Mercury, Venus and Mars, as of its satellites; for the reasons indica- ted in Section 3, chapter 9. Indeed, if we wish to pursue every nicety, not even in the hypothesis of Kepler and Boulliau is the Sun the centre of the Planetary orbit, since they determine that orbit to be not a circle but an Ellipse, and place the Sun not in the centre of the Ellipse but only in one of the umbilici, or foci, of the Ellipse. But we do not lean on this last subtlety, because in every hypothesis of a Planetary orbit, on account of the Eccentricity required to excuse the anomaly, its centre is distant from the centre of the Universe — except the orbit of the Earth, whose centre, in the opinion of Copernicus, is in the very centre of the Universe, and is distant from the Sun only by as much as the Eccentricity of the Solar orb is in the hypothesis of the others.

[Margin: 2nd Reply.] I reply, secondly, by retorting the argument thus: *That body ought to be set in the centre of the Universe which is the centre of the motion of both the non-wandering and the wandering stars, of both the old and the new phenomena, and of both the elementary, or subcelestial, and the celestial bodies. But such a body is not the Sun but the Earth. Therefore not the Sun but the Earth ought to be set in the centre of the Universe.* The MAJOR certainly carries far greater probability than if the centre of the Universe is referred only to the

circulations of some Planets, all the other parts of the World being neglected. The MINOR has no difficulty except as regards the Planets, for it seems that not the Earth but the Sun is the centre of the Planetary system. But by the very fact that the Earth is the centre of the motion of the great Luminaries, namely the Moon and the Sun, it is also, through them, the centre of the other Planets, if these are determined to be carried about the Sun, as Tycho will have it. In our system, however, the difficulty is less: for the Sun is the centre only of Mercury, Venus and Mars, these being the satellites of the Sun and belonging to the same heaven, while the Earth is the centre of the orbs of Jupiter and Saturn and, through them, of the Jovian and Saturnian satellites.

III. Argumentum à Fonte Luminis & Caloris.

3. The argument from the source of Light and Heat.

[Margin: Kepler's opinion on the source and place of light.] VII. This argument seemed splendid indeed to Kepler, in the *Astronomiae Pars Optica*, chapter 1, page 7. There, having brought forward many praises of light — as the most excellent of visible things in the world, the matrix of all the faculties of animals, and the bond of the corporeal and the spiritual world, as he himself thinks, and therefore created by God on the very first day of the world — he added: *The Sun, then, is a certain body; in it is this faculty of communicating itself to all things, which we call light; to which, even for this reason alone, the middle place in the whole world is owed, so that it might diffuse itself equably and perpetually into the whole orb.* [Margin: Praises and place of the Sun, from Kepler.] But in the same work, chapter 6, from page 221 to 226, he pours himself out wholly in praises of the Sun, and attributes to it a density and quantity of matter as great as there is in the whole aethereal air, and yet such diaphaneity that our eye sees its depth and centre; and a soul, or vital faculty; and many other things. But to our purpose he says *that the office of the Sun in the world is, by the admission of all, that of the Heart in an animal, and that the motions of the Planets are dispensed from the Sun, etc.* Then in the *Epitome of Copernican Astronomy*, Book 4, page 448, he says that if the whole world, which is spherical, needs the light and heat of the Sun equally, the Sun is best placed in the middle, from where these may be distributed equally to all quarters of the world; that this happens more equably and more rightly if it rests in the centre of the World than if it goes round about the centre and, by receding from some and approaching others, illuminates and heats these more and those less; and that the comparison of a lantern, in whose middle we place the light, is not to be laughed at. But quite new are the things he adds on this subject in the same place, saying: *Of light, moreover, a particular demonstration is woven, supposing fitness, not necessity. Imagine the sphere of the Fixed stars to be a concave mirror: it is known that an eye placed in the centre of such a mirror sees itself on every side; and that if a light is in the centre, it is reflected on every side from the concave surface at right angles, and the reflected rays meet again in the centre. But this can happen at no other point of the*

concave except the centre. Therefore, since the Sun is the source of light, the eye of the world, the centre will be owed to it, so that (being itself, in the divine symbolism, the Father) it may contemplate itself in the whole concave surface (which bears the symbol of the Son of God), [Margin: Kepler's symbol of the Most Holy Trinity.] and may be well pleased with its own image in it, and by illuminating may make itself illustrious, and by heating may kindle itself.

VIII. But before Kepler, Copernicus, in Book 1, chapter 10, using another comparison, had assigned this very seat to the Sun in these words: [Margin: The praises and place of the Sun, from Copernicus.] *In the middle of all, moreover, resides the Sun. For who in this most beautiful temple would place this lamp in another or a better place than that from which it can illuminate the whole at once? For not ineptly do some call it the lantern of the world, others its mind, others its ruler; Trimegistus [Hermes Trismegistus] calls it the visible God, the Electra of Sophocles the all-seeing. Thus indeed the Sun, as though residing on a royal throne, governs the family of the stars that circles about it.* [Margin: And Pliny the Elder's.] To this may be drawn what Pliny the Elder utters most magnificently about the Sun in Book 2, chapter 6, and what we have recited from him in Book 3, chapter 1. From this, then, the following argument is built.

[Margin: 3rd Argument in Form.] IX. *That body ought to be set in the centre of the Universe which is the cause and source of the light and heat diffused through the whole world. But such is the Sun; therefore the Sun ought to be set in the centre of the universe.* The MINOR is certain with everyone. The MAJOR is proved both from the equal communication of heat and light, which ought to happen and cannot unless the source of light and heat is equally distant from all parts of the world; and from the comparison of the mirror, the lamp, etc., of which at numbers 7 and 8.

The reply is made by distinguishing the Major: denying it if the body is not the universal cause of light, and the very things which receive light from it do not receive light equally; but conceding, or granting, it if the body is the universal cause and illuminates all things in the same way. But in this sense the Minor is denied. For the Sun neither is the cause of light in the Fixed stars, as is plain from what was said in Book 6, chapter 2, even with Kepler himself agreeing; nor does it illuminate the Earth and the Planets equally — both on account of its unequal and from time to time variable distance from the Earth, and that of the Planets from it, and on account of its manner of illuminating them. For we discern some phases in the Moon; others in Mercury and Venus, which are sometimes seen sickle-shaped; others in Mars, which sometimes appears gibbous but never sickle-shaped; others in Jupiter and Saturn, which to sense always appear round — granted that these too receive their primary light from the Sun. That equality, therefore, is feigned, and put forward with little consideration. Nor is the comparison from the mirror valid either: since the sphere of the Fixed stars is not a mirror of the Sun, for otherwise the whole of it would shine together; nor are the Fixed stars images of the Sun, for otherwise they would not have their light from themselves, and all those equally distant

from the centre of the world would appear of the same magnitude, and at any point whatever of the celestial concavity from which rays could reach our eyes by reflection. It suffices, then, if the Sun is in such a place that it can illuminate the Earth and the Planets all round — but in that manner and measure which the end of divine Providence requires.

IV. Argumentum à Fonte Motus.

4. The argument from the source of Motion.

X. We have already heard this argument too hinted at by Copernicus in Book 1, chapter 10, when he calls the Sun the ruler and governor of the Planets driven round it. But Rheticus added force to it in his *Narratio prima*. [Margin: Rheticus's opinion on the source of motion and on the place of this source.] For when he had said: *In the common principles of Astronomy one could indeed see that all the celestial appearances direct themselves to the mean motion of the Sun, and that the whole harmony of the celestial motions is constituted and preserved by its governance. Hence the Sun was also called by the ancients* [Greek: χορηγὸς (chorēgos, "leader of the chorus")]*, governor of nature, and King. But how it should carry on this administration — whether in the way that God governs this whole universe, as Aristotle most beautifully depicts in* [Greek: περὶ κόσμου (peri kosmou, "On the World")]*, or whether it would act as God's administrator in nature by itself traversing the whole heaven and resting in no place — does not yet seem to be wholly explained and settled.* Having set these things down beforehand, I say, he adds shortly after: *The former mode of governance has been rejected, the latter received. But my Lord Doctor and Teacher* — he means Copernicus — *has decided that the condemned account of the governance of the Sun in the nature of things is to be recalled, yet so that the one received and approved too may keep its place. For he saw that in human affairs, too, there is no need for the Emperor himself to run [?] through the cities one by one in order to discharge, in short, the office laid on him by God; nor for the heart to migrate into the head, or the feet, and the other parts of the body for the conservation of the living creature, but for it to preside over its office through other* [Greek: ὄργανα (organa, "organs" or "instruments")] *destined by God for this.* After this he says, lest the mean motion of the Sun in the other planets should serve in imagination alone rather than have a true efficient cause, this was brought about by the annual motion of the Earth in the great orb; for from this the cause is ready to hand why the mean motion of the Sun flows into the theory of all the planets.

[Margin: Kepler's teaching on the source of motion and the place it holds.] XI. But Kepler strives to advance this very doctrine with other reasons, in the introduction to the *Commentaries on Mars*, page 4. There, from the fact that the Planets are spurred on by their approach to the Sun and checked, or slowed, by their recession from it, and that this same thing happens to the Earth if the Earth moves annually, he gathers by a physical conjecture that the Sun is the source of the motion of the Planets and of the Earth, and says: *It is therefore very*

likely that the source of the Earth's motion is where the source of the motion of the other five Planets is: namely, likewise in the Sun. It is therefore likely that the Earth moves, since a likely cause of its motion appears. So, with no delay interposed, he argues conversely thus: *On the contrary, that the Sun stays in its own place in the centre of the world is likely both for other reasons and above all for this one: that in it lies the source of motion of at least five Planets. For whether you follow Copernicus or Brahe, for both of them the source of the motion of the five Planets is in the Sun; in Copernicus also of a sixth, namely the Earth. But it is more likely that the source of all motion stays in its own place than that it moves.* But because he saw that the phenomena of the Sun are saved in the Tychonic hypothesis — that the Sun is slow in its recession from the Earth and swift in its approach, and that the Sun can be the source of light and yet move about the Earth — a little later he added these words: *Upon this most certain conclusion, then, by the physical conjecture used above, this Physical philosopheme would have to be built: that the SUN, together with that whole very great burden of the five Eccentrics (to speak crudely), is moved by the Earth; or that the source of the motion of the Sun and of the five Eccentrics attached to the Sun lies in the Earth. But let the two bodies, of the Sun and of the Earth, be inspected, and let judgement be made of both: to which of them does the source of the motion of the other body more fittingly belong? Does the Sun, which moves the other Planets, move the earth; or does the Earth move the Sun, the mover of the others, so many times larger than itself? Therefore, so that we are not compelled to concede that the Sun is moved by the Earth, which is absurd, immobility must be conceded to the Sun and motion to the Earth.* Kepler has, moreover, another reason peculiar to this hypothesis: that, according to his own fictions, the Sun moves the Planets by a magnetic force diffused by means of light, by which it seizes them and leads them round, as I have already explained in Book 3, chapter 2, number 7. Gathering this argumentation into a few words, then, one may reason thus for the Copernicans.

[Margin: 4th Argument in form.] XII. *That body ought to be at rest in the centre of the Universe which is the source of the motion of the Planets. But the Sun, and not the Earth, is the source of the motion of the Planets; therefore the Sun, and not the Earth, ought to be at rest in the centre of the Universe.* The MAJOR rests on likelihood, which could be strengthened from the analogy of a spring: for a spring does not move, but the river or stream flowing from the spring does; and in mechanics the movers usually stand in a fixed place, so that from there they may move other bodies more firmly. The MINOR is proved, first, from the fact that the motion of the Planets in their second anomaly is adjusted to the mean motion of the Sun — or, as the more recent writers will have it, to its true motion; next, from the magnetic faculty of the Sun, by which it leads the Planets round; and finally because it is more likely that the Sun is the source of the motion both of the Planets and of the Earth than that the Earth is the source of the motion of the Sun and, by means of the Sun, of all the Planets.

The reply, nevertheless, is made by distinguishing the Major. It is denied if that body is not the universal source of motions — that is, of all the Planets,

the Fixed stars, the new Phenomena, and the Elements and elementary bodies — or if it is not a source but an objective exemplar or rule of motions. It is conceded, or granted, if the body is of this kind; and in that sense the Minor is denied. For the Sun is the source neither of the motion of the Elements or of the elementary bodies, nor of the Fixed stars, nor of the satellites of Jupiter and Saturn. Nor is it even the source — that is, the efficient cause — of the motion of the Planets, as Kepler gratuitously feigns, but only an exemplar, which they in part follow or imitate by their motion, as a standard-bearer moves a column of soldiers, and a chorus-leader a chorus of dancers. Therefore the burden of carrying the Eccentrics of the Planets does not fall on the Sun, as though it were a porter, and Kepler's comparison is too crude, as he himself admits. Nor does the Earth move the Sun effectively, or by sustaining it, but objectively and finally: inasmuch as the Sun is moved about the Earth, and for the sake of those who dwell on it, by its own Intelligence — and in a metaphorical motion and mode of moving of this kind we deny that there is any absurdity. Indeed, taking the occasion of the question raised by Rheticus, it is likely that among the other ends intended by God this was one: that it should be evident, from the Sun's very agitation and restless course, that the Sun is not God but the minister of God, ordered to rise upon the good and the bad, and to carry the torch before all the inhabitants of the Earth. For I remember having read in the history of East India that the King of Peru, called Iinga, a worshipper of the Sun even on this very account — that the Sun runs round with such diligence as to help everyone — was refuted by a Spaniard: from this, he said, it should rather be gathered that the Sun is not God, since immobility befits God. What Kepler added about the magnitude of the Sun with respect to the Earth will be dissolved in the following argument.

V. Argumentum à Mole Solis ac Telluris.

5. The argument from the Bulk of the Sun and of the Earth.

[Margin: Kepler's argument for the annual motion of the Earth.] XIII. What is our fifth argument is Kepler's sixth, in Book 4 of the *Epitome of Copernican Astronomy*, page 544, beginning from these words: *For it is more credible that the body around which smaller ones go round is large.* He supposes it certain that Saturn, Jupiter, Mars, Venus and Mercury are smaller than the Sun, and likewise that the Moon is smaller than the Earth, which it goes round, and the Jovian satellites smaller than Jupiter. Then he concludes: *Now if the Sun moves, the Sun, the greatest body, and the three superior planets, each of them larger than the earth, will go round the smaller earth. It is therefore more credible that the Earth, a small body, goes round the great body of the Sun.*

[Margin: Reply.] The reply, however, is that this is not true unless other things are equal. For if what is lesser in bulk is greater in power and in the excellence of its end — and of this kind is the Earth, taken not bare but together with its inhabitants — it is more credible that it rests, and that the other bodies,

which are to serve it by their motion, move about it. Besides, the sphere of the elements, about which the Sun moves, is greater in bulk than the Sun; and yet the Copernicans move it, together with the whole Lunar heaven, about the Sun, which is so much smaller. So the argument, if it were valid, could be turned back against them.

VI. Argumentum ab Indigentia, & à Fine Motus.

6. The argument from Need, and from the End of Motion.

[Margin: Another argument of Kepler's for the annual motion of the Earth.] XIV. The Sun in no way needs the Earth, but the Earth needs the Sun and the other stars: it is fitting, therefore, that the Earth itself should move, and by its motion seek for itself the things it needs. But this argument has already been answered in chapter 5, numbers 31 and 32. As for the end of motion, Kepler, in the *Epitome of Copernican Astronomy*, Book 4, page 549, philosophizes thus. The Earth, he says, in almost these very words, is the dwelling of the contemplative creature; and it was not fitting that man, the inhabitant and observer of this world, should reside in one place of it as though in a closed chamber, for in that way he would never have arrived at the measurement and contemplation of stars so remote. It was necessary, therefore, that just as surveyors usually take different stations, so man, making use of the annual translation of the Earth, should walk around as though by navigation, so that he might more correctly view and measure the several members of this great house. [Margin: Reply to the argument.] But Kepler does not see that this was not necessary either. For it is abundantly sufficient for a man to come out into the open and contemplate the stars; or, if some motion is needed, to walk about the resting earth himself. Nor does the motion of the Earth contribute anything to this for him, since through it he comes no nearer to the Planets than in the hypothesis of a resting Earth; and to the fixed stars he is brought by no sensible approach through the motion of the Earth, since the whole annual orb is like a point with respect to the sphere of the Fixed stars, in the opinion of Copernicus. Conversely, if approach to the stars had been needed in order to measure the motions, diameters and intervals of the Planets and the Fixed stars — as though one had to measure them with ten-foot rods or ropes — this argument would prove too much: namely, that it would also have been needed for man to approach as near as possible to each of the stars, which is plainly quite false. Let Kepler cease, then, to assail the rest of the Earth with such light arguments, or to try with these little machines to move it from its seat; and let him remember that men need the stars not as masters, but as servants serving at God's command.

VII. Argumentum ab Analogia Microcoſmi.

7. The argument from the Analogy of the Microcosm.

[Margin: Another, very light argument, and its solution.] XV. Just as in the Microcosm, that is, the small world — namely man — the feet are moved with a progressive motion but the head is not, so in the Macrocosm, or great world, the Earth has the role of the feet, and accordingly it, rather than the Sun, ought to be moved. But both sides of the parity are denied. For the Earth is not the foot of the world but rather, according to the sacred Scriptures, the immobile footstool of the feet of God; nor, according to the Copernicans themselves, is it the lowest part. And even if it were, it would not have to be moved with that progressive motion with which the feet of an animal are moved, or for the same end, nor carry the head round with it; otherwise the Sun, or the whole heaven, as the head, would also be moved along with its motion. And so this argument too would prove too much, if it carried any weight amid so great a lightness of reasoning.

VIII. Argumentum à Congruenti Craſſitie Cælorum.

8. The argument from the Fitting Thickness of the Heavens.

XVI. Among the other things that seem to favour the Copernican system is, above all, the distinction of the heavens, on account of which no Planet enters the domain of another, and the fitting filling of the space set between them. [Margin: Copernicus's reason for placing the Earth between Mars and Venus.] Copernicus pointed to this in Book 1, chapter 10, when he said: *But with all these resting on one middle, that is, on the Sun, it is necessary that the space left between the convex orb of Venus and the concave of Mars be distinguished as an orb, or sphere, too, homocentric with them in both its surfaces, which may receive the Earth with its attendant Moon and whatever is contained beneath the Lunar globe. For we can in no way separate the Moon from the Earth, etc., especially since in that space we find a place for it that is fitting and amply sufficient.* [Margin: And Baranzano's.] Taking occasion from this, Dom Redento Baranzano, in Part 1 of the *Uranoscopia*, question 3, doubt 10, member 2, argues thus for Copernicus from the thickness of the spheres. Since the thickness of the Lunar heaven is twenty-one terrestrial semidiameters, the thickness of the heaven of Mercury 103, of Venus 933, of the Sun 44 and of Mars 7640, it would seem unfitting and far from all proportion that the Sun, the chief among the stars and of such great power, should have so tiny a heaven unless it were in the centre of the world, while Venus, which is smaller than it, and Mars had so great a depth in their heavens. This disproportion is certainly removed if the Sun is placed in the centre of the World, and the Earth with the Lunar heaven between Mars and Venus; for in this way the thicknesses of the spheres increase step by step: the sphere of Mercury comes out larger than the Sun, the sphere of Venus larger than Mercury's, and the thickness of the elementary sphere together with the heaven of the Moon larger than the sphere of Venus. One could also reason thus against the old hypotheses with the *Philolaus* published at Paris, chapter 7. The concave of the Sun and the convex of Venus are distant from

the centre of the earth by 1070 terrestrial semidiameters, according to certain Alphonsines; the concave of Venus and the convex of Mercury by 162⅔; and the concave of Mercury by 50⅔ semidiameters; but the Moon at the apogee of its Eccentric and Epicycle is distant 64 semidiameters 10′. There are lacking, therefore, 13 semidiameters of the earth and 46′ in the space assigned below the concave of the Sun, for it to be able to contain the whole orbs of Venus, Mercury and the Moon. This absurdity, however, is not found on this head in the Ptolemaic hypothesis, which assigns to the concave of the Sun a distance of 1146 semidiameters of the earth, as Chiaramonti noted in his *Antiphilolaus*, Part 1, chapter 7. Setting this aside, then, there remains the former argument of Copernicus and Baranzano, reduced to the following formula.

[Margin: 7th Argument in form.] XVII. *Unless the Sun is set in the centre of the Universe, and the Earth, with the Elements and the Lunar heaven, between the convex of Venus and the concave of Mars, the due proportion between the thickness of one sphere assigned to the Planets and that of another is not preserved. But it is absurd that the said proportion should not be preserved. Therefore the Sun must be set in the centre of the Universe, and the Earth, with the Elements and the heaven of the Moon, between the convex of Venus and the concave of Mars.* The MINOR seems certain from the orderly manner of the supreme Maker in determining the thickness of the heavens. The MAJOR has been proved, because to the Sun, the greatest of the planets, the smallest heaven, or the least thick possible [?], would belong, while to Venus and Mars, which are far smaller Planets, a far greater heaven would have been given, and the space between the convex of the Sun and the concave of Mars would be excessive and idle.

[Margin: 1st Reply.] The reply is made by denying the Major: first, because it would be a greater disproportion and absurdity for the Sun, which is the greatest of the Planets, to have no heaven than to have a small one, and for the Earth with the other elements — which are commonly reckoned subcelestial bodies, and of the most diverse properties — to be placed in the heaven. Moreover, for the Sun set immovably in the centre of the universe there would be no heaven at all; the whole space between it and Mercury would belong to the heaven of Mercury, since a heaven is ascribed to mobile Planets so that they may go round through it. Next, if Mercury and Venus are assigned to the Sun as satellites, there is no longer any reason why a distinct heaven should be ascribed to them, just as none is assigned to the companions of Jupiter and Saturn. Hence by the heaven of the Sun must be understood that whole heaven in which Venus and Mercury too move; and so it will be a very thick heaven. It will be far ampler still if, according to our system, Mars too belongs to the heaven of the Sun as a Satellite; for in this way a heaven of very great thickness will befit the greatest of the Planets, attended by the greatest satellites. On this thickness see what was said in Section 3, at the end of chapter 9. The remaining objections brought against Ptolemy and Alfonso, as men who always place Venus and Mercury below the Sun, are not valid against the Tychonic system or ours.

IX. Argumentum à Diſtinctione Cælorum.

9. The argument from the Distinction of the Heavens.

XVIII. Now, on the testimony of the Telescope, we are compelled to admit that Venus and Mercury move now below and now above the Sun; and the observations of Mars and of the Sun, and of the parallaxes owed to them, in such a way that fitting equations of the motions follow from them, prove well enough that Mars in perigee comes nearer to the Earth than the Sun. On this see what we said in Book 7, Section 2, chapter 3, scholium 4, and Section 6, chapter 4, scholia 3 and 4, and chapter 10, scholium 1. Now if we attribute to the Sun motion, and a place among the Planets already mentioned, it follows that those Planets, or at least Mars, penetrate the heaven of the Sun — which was objected as an absurdity against the Tychonic system by Rothmann, Hérigone, Tanner, Malapert, Amico and Argoli, as we said in Section 3, chapter 4, number 5, and chapter 8, number 5. [Margin: Kepler's argument against Tycho's system as regards the place of the Sun.] Indeed Kepler himself, in the *Epitome of Copernican Astronomy*, Book 4, page 544, puts it thus: *If Brahe's account holds, so that the orbit of Mars is one and a half times the orbit of the Sun, the body of Mars will at certain times move into that point of the world's space in which at other times the Sun was — which is quite incredible of primary Planets — and so their regions, which they pass through, are confounded; whereas in Copernicus they are not only distinct but separated by very wide empty intervals.* Anyone who wants a specimen of this difference should consult the figures of the systems set out by us: the Tychonic and ours in Section 3, chapters 8 and 9, and the Copernican in this Section 4, chapter 4, number 15. For in the Tychonic system and in ours the circle of Mars intersects the circle of the Sun's orbit when Mars approaches perigee; but in the Copernican the whole circle of Mars stays apart from the Sun among the orbits of the other planets, and does not intersect the great orb of the Earth; and the great orb itself performs what would otherwise be performed in Ptolemy by the Epicycle of Mars, and in Tycho by the orb of the Sun; and it is the Earth that approaches Mars when Mars stands opposite the Sun, and that is why Mars then appears so much larger than when it is far from perigee, and why, for the same reason, it undergoes a greater parallax than the Sun. This objection, moreover, has greater force with those who retain solid orbs; for they will not admit this penetration of Mars into the heaven of the Sun, for two reasons: namely on account of solidity, and on account of the distinction of the heavens. [Margin: Galileo's words on the same argument.] And so Galileo too, in Dialogue 3 on the system of the world, page 253, says: *Would you not call it, Simplicio, a very great absurdity if in the system of Ptolemy Mars should lower itself so far that, having broken through the orbit of the Sun, it descended below it and came nearer to the Earth than the solar body itself, and a little later was raised above that same body by an enormous interval?* Now to the form of the argument.

[Margin: 9th Argument in form.] XIX. *It is absurd that the distinction of the heavens should not be preserved, and that the heaven of one primary Planet should be per- meated by another primary. But unless the Sun rests in the centre of the world, and the Earth in its place performs an annual motion through the great orb, Mars, which is a primary Planet, sometimes penetrates the heaven of the Sun, which is itself also a primary Planet. Therefore, unless the Sun rests, etc., and the Earth moves, etc., an absurdity follows.* The MAJOR seems evident from the order owed to the more important parts of the world, such as the elements, which God set apart, and the heavens — especially since these are a kind of image of that hierarchical order which is found in the intelligible world, that is, among the nine choirs of Angels. The MINOR is proved because Mars, when opposite the Sun, appears at either of its perigees larger than itself at apogee: sixty times larger as regards the disc, and seven or eight times as regards the diameter, if it is viewed through a Telescope. Indeed, from our observations, its diameter near apogee ought to appear of only 10″ 6‴, but at either perigee of 92″ — that is, a diameter nine times larger; on this we said more in Book 7, Section 6, chapter 10, scholium 1. Moreover, if the apparent place of Mars, often observed in the acronychal position — that is, when it rises in the evening and is opposite the Sun — is to be reconciled by correct prosthaphaereses with the mean place of the tables, one must apply greater parallaxes to Mars than to the Sun, that is, a smaller distance of Mars from the earth in that position than of the Sun, as was said in Book 7, Section 2, chapter 3, scholium 4, and Section 6, chapter 4, scholia 3 and 4, and chapter 7, number 3. But these appearances cannot be saved, and brought into agreement with the due measure of the orbs, unless Mars comes very near the Earth and passes from a greater distance than the distance of the Sun to a smaller one, through the middle, or equal, distance; and unless, being sometimes without latitude at the moment when it is as far away as the Sun, it passes through that point of the Ecliptic through which the Sun passed that year or is about to pass, if the Sun is supposed to move through its annual orb. So it comes about that the Sun invades the heaven of Mars, and Mars the heaven of the Sun, in turn, with their rights and domains thrown into confusion.

[Margin: 1st Reply, but of the unskilled.] Someone might perhaps reply, first, by denying the Minor and its proofs, calling into suspicion of fallacy the observations of Tycho and others — as I regret has been done by some, whom I named in Book 7, Section 6, chapter 4, scholium 4. But in this matter Kepler, Maginus, Boulliau, Lansbergen and all the most skilled practitioners of the more recent Astronomy accepted those observations as valid. And that appearance of Mars as sometimes larger than Jupiter appears, of which Copernicus speaks in Book 1, chapter 10, and other similar ones reported by us in Book 7, Section 6, chapter 10, scholium 1, cannot be reconciled while preserving the commensuration of the orbs of Mars and the Sun deduced from the motions of both, unless Mars can sometimes come nearer to the Earth than the Sun does. Therefore the proof of the Minor, as regards this part, can be denied only by those less skilled in Astronomical subtleties.

[Margin: 2nd Reply, but a forced one.] Others perhaps might reply, second, by likewise denying the Minor and its proof. They would say that the heaven of the Sun is not an entire sphere but only a segment, round in the manner of a wheel, occupying as much aethereal space as the body of the Sun takes up when carried by its centre along the Ecliptic; that the heaven of Mars is likewise a round segment in the manner of a kind of wheel, occupying as much space as the bulk of Mars itself and, besides, as much as both its greatest elevation upward and its declination in latitude require; and that it can happen that the smaller wheel of the Sun is inserted so obliquely into the wheel of Mars that Mars at perigee is nearer to the earth than the Sun and yet never passes through the wheel of the Sun, the latitude of Mars so requiring. But these things are hard to maintain, and they would be said with little consistency, considering all the cases which the Theory of the Sun and of Mars admits by its nature, if the brief duration of the world does not by accident extend to these cases. Nor is there any need, for the solution of the argument proposed, of fictions of this kind, violently forced into the hypothesis of these Planets.

[Margin: 3rd Reply.] The reply, therefore, is made, third, by distinguishing the Major: denying it if this absurdity cannot be avoided without a greater absurdity; conceding it if it can. But in this sense I deny the Minor — that is, that with the Sun placed in the centre of the World and the Earth moved through the annual orb, the distinction of the heavens is preserved in such a way that a greater absurdity is avoided. For two far greater inconveniences are incurred. One is that the Sun is thrust down from the heaven into the centre of the world, so that in fact it has no heaven of its own, which is worse than sometimes admitting the path of another Planet into its own heaven. The other is that the Earth, with the whole elementary sphere, is transferred into the heaven, against common sense and against the order owed to the World, which requires rather that the Heavens be distinguished from the Elements by separate regions than that the Heavens be distinguished among themselves, or the Elements among themselves. But if the Copernicans have scorned this common sense of very many wise men, they cannot fairly take it ill if someone says, against their sense, that it is not absurd for the heaven of one Planet to be mixed, or interwoven, with the heaven of another.

[Margin: 4th Reply.] I reply, fourth: granting the Major, and conceding that part of the Minor in which it is said that Mars penetrates the heaven of the Sun, I deny that part in which Mars and the Sun are said each to be a primary Planet. For among the Copernicans the Sun is not even a Planet, since it is in no way moved by a motion of translation, much less by an errant and wandering motion. Among the others it is indeed a Primary Planet; but Mars, in our system, is not primary if compared with the Sun, for it is the Sun's largest satellite, and stands to the Sun as the outermost Satellite of Jupiter stands to Jupiter. Accordingly it is no wonder if, together with Venus and Mercury, it has been admitted within the same heaven of the Sun, as into the very spacious hall of its King. But if this likewise seems absurd to the Copernicans — namely

that Mars, one of the three superior Planets, is made by us from a primary into a secondary Planet and a satellite of Jupiter [?] — we say that it is much more absurd to make the Sun from a Planet into a non-Planet, to make the Earth with the sphere of the elements from a non-Planet into a Planet, and to make the Moon, which is one of the great luminaries, a secondary Planet and companion of the Earth. Nor will this dispute be ended unless one party gratuitously grants the other what that party supposes, although it is the very point in question.

[Margin: 5th Reply.] A fifth reply could be made by denying the Major. For since it is established that the heaven of the Planets is fluid, and that the Planets complete their courses freely in the liquid aether, there is no greater need to assign them distinct regions one by one than there is to assign distinct regions to the birds of the air and the fishes of the ocean; and a single Heaven suffices for all the Planets. If, however, someone still holds fast to the distinction of the heavens, at least by designation, let him use the 3rd or the 4th reply.

X. Argumentum ab Interuallis, & Numero Planetarum, ex quinque Corporum Regularium dimenſione deſumptis, ſeu ex Kepleri Myſterio Coſmographico.

10. The argument from the Intervals and the Number of the Planets, taken from the dimensions of the five Regular Bodies, or from Kepler's Mysterium Cosmographicum.

XX. This is that offspring of Kepler's genius, conceived by him not long after the year 1589, first published in the year 1596, and finally polished and reprinted in the year 1621. He was so pleased with it that he applied almost all the machinery of Astronomy to preserving its structure, and from it ordered almost the whole economy of this Art. It is, in short, the thing for love of which, above all, he adhered to the sect of the Copernicans, and he never ceased to establish it with all his effort. Here, then, the points necessary for grasping the force of the argument are to be gathered into a few words, reserving more for another place. [Margin: Kepler's discovery and the *Mysterium Cosmographicum*.] While he was inquiring more deeply into the proportion of the celestial orbs and into the causes of the number of the heavens, Kepler recognized that, if the Earth were received into the heaven between Mars and Venus and the Sun rested in the centre of the Universe, while the Copernican intervals of the Planets, and so also of the earth, were corrected somewhat, those intervals could be distributed according to the proportion that the five Regular bodies — otherwise called Platonic — have when inscribed in order one within another, with orbs between them. Since these bodies are only five, and there cannot be more or fewer, six Planets are required so that their five intervals may be filled. From this he judged that a necessary cause could be given for the number six of the primary Planets; for in place of the Sun he counts the Earth, together with the Moon as a kind of secondary Planet. [Margin: What are the Regular Bodies?] Now the Regular bodies are *Solid figures which are contained by planes*

that are equilateral and equiangular and equal among themselves. Of this kind is the *Cube*, or *Hexahedron*, that is, a figure bounded by six equal square faces; with 12 sides, and with angles solid, 8 in number. Next the *Tetrahedron*, or equilateral Pyramid, bounded by four equal equilateral triangles, with six sides and 4 angles; the *Octahedron*, bounded by eight equal equilateral triangles, with 12 sides and 6 angles; the *Dodecahedron*, bounded by twelve equal Pentagons, with 30 sides and 20 angles; and finally the *Icosahedron*, bounded by twenty equilateral and equal triangles, with 30 sides and 12 angles. That besides these five there can be no other bodies contained or bounded by plane faces equal among themselves and equilateral is demonstrated by the interpreters of Euclid — especially Clavius, in Book 13 of the *Elements*, in the scholia to proposition 18 — and by Kepler himself in Book 4 of the *Epitome of Copernican Astronomy*, p. 467. And in Book 2 of the *Harmonics* [Kepler's *Harmonice Mundi*], proposition 25, he rightly notes that the Cube, the Tetrahedron and the Dodecahedron are simple, and therefore primary, while the rest, the Octahedron and the Icosahedron, are secondary, as being composite. For the three former have the simplest angle, that is, a trilinear one, and a plane face of their own, distinct from the others; whereas the rest have an angle comprehended by more lines than three, and share their plane faces with the Tetrahedron.

XXI. Moreover, Kepler himself hands down this whole doctrine, compressed as it were into a compendium, in the preface of the *Mysterium Cosmographicum* and in chapters 2 and 14; in the preface of the *Harmonics*, and in Book 2 from proposition 25, and Book 5, chapter 9; and in Book 4 of the *Epitome of Copernican Astronomy* from p. 455. First, then, it is to be noted, on the authority of Aristotle and Plutarch, that the five Regular bodies were long ago fitted by the Platonists and Pythagoreans to the bodies of the world. Proclus did the same, on Book 13 of Euclid, asserting that Euclid set the five Regular bodies before himself as his ultimate end, and wrote everything he handed down in the *Elements* for their sake, except what leads to perfect Number. Petrus Ramus [Pierre de la Ramée], by contrast, contends in his *Scholae Mathematicae* that these five bodies should be removed from the end of Euclid's *Elements*, and Lazarus Schonerus [Lazarus Schöner] thought them of no use; against these, see Kepler in the preface of the *Harmonics*. Indeed, I read the following in Plutarch, Book 2 of the *De placitis*, chapter 6: *Since there are five solid figures, which are called mathematical, Pythagoras said that the Earth was made from the cubic one; Fire from the cone, or Pyramid; Air from the Octahedron, that is, the body of eight seats; Water from the Icosahedron, that is, the body of twenty seats; and the globe of the universe from the Dodecahedron, that is, the body of twelve seats. Plato Pythagorizes in all these things.* Kepler investigates the correspondences of this distribution, without any mention of Plutarch, in Book 2 of the *Harmonics*, prop. 25, and in the *Mysterium*, chapter 2. But there, and in that preface, he suspects that the Pythagoreans symbolically hid the names of the Planets under the names of the Elements: under the name of Earth, Saturn, nearest to immobility through its slowness; under the name of Water, Venus, who is feigned to have been

born from the foam of the Sea on account of the humours subject to her, and is therefore called Αφροδίτη [Greek: Aphroditē, the foam-born]; under the name of Air, Mercury, for the mobility of his speed; under the name of Fire, Mars, who is for that reason called Pyrois, from fire. But Proclus too said that, among other things, this is the end of Geometry: to teach how the heaven received figures fitting its several parts — namely from that great Demiurge who disposed all things in number, weight and measure. Kepler therefore judged more truly that the five intervals of the celestial orbs enclosing one another arose from those five figures; and so, if these are five, the primary Planets had to be six, just as five fingers are required to bound four intervals on one hand. The order and distribution of these bodies among the heavens of the Planets is handed down by Kepler, in the form in which he first conceived it, in this formula in the preface of the *Mysterium*: *The Earth is the circle that is the measure of all. Around it circumscribe a Dodecahedron; the circle comprehending this will be Mars. Around Mars circumscribe a Tetrahedron; the circle comprehending this will be Jupiter. Around Jupiter circumscribe a Cube; the circle comprehending this will be Saturn. Now inscribe an Icosahedron in the Earth; the circle inscribed in it will be Venus. Inscribe an Octahedron in Venus; the circle inscribed in it will be Mercury. There you have the reason for the number of the Planets.* Accordingly he counts the Moon as a secondary Planet and Companion of the Earth; the Sun, however, he does not reckon among the Planets, but places it in the centre of the Planetary system, as the source of light, heat and motion. Having examined the intervals at which the Planets stand from the Sun according to the Copernican measures — though somewhat emended by himself and by Mästlin — he concludes that those intervals are capable of the order and distribution already mentioned, as he teaches from chapter 2 of the *Mysterium Cosmographicum* to chapter 20, and in the *Epitome* from p. 468. Kepler grants, however, that the Copernican intervals come so near the proportions of those figures that they fall short only in some very small degree; but he says that this arises because the archetype of this mobile world consists not only of the beauty of the regular bodies but also of the Harmonic proportions and the concord of six voices, to whose Idea the fastest and the slowest motions of the Planets had to be tempered; and this tempering could not have been achieved unless the Harmost had varied those figural intervals a little.

XXII. Someone might perhaps wish us to represent this order and symmetry here in some diagram. But we cannot do so exactly, since those solid figures cannot be drawn in a plane in such a way as to keep the number of all their sides, planes and angles together with their magnitude; and if we used plane figures in their place, we would give the Reader occasion for manifold error. Let the diagram below suffice him, then. In it, from A — the centre of the annual orb, near the Sun according to Copernicus, but the Sun itself according to Kepler — let there be described, each within two circles, the orb of Saturn ♄ with its thickness, that of Jupiter ♃ with its own, and that of Mars ♂ with its own; and the Great Orb of the Earth, with the sphere of the Elements and the patio [?] of

the Moon's excursion, the whole of which we have also marked off above and below with a small black globe. Then, likewise within two circles, let there be described from the same centre A the orb of Venus ♀ with its thickness and the orb of Mercury ☿ with its own. This done, between the orbs of Saturn and Jupiter let the letter C be inscribed on either side, C, C, signifying the Cube to be inscribed in the Orb of Saturn but circumscribed about the orb of Jupiter. Between the orbs of Jupiter and Mars let the letters T, T be inscribed, indicating the Tetrahedron to be inscribed in the orb of Jupiter but circumscribed about the orb of Mars. In the third space, that is, between the orb of Mars and the annual orb of the Earth, let D, D be marked, to signify that in that space the Dodecahedron is to be inscribed in the orb of Mars but circumscribed about the annual orb of the Earth. In the fourth interval, namely between the annual orb and the orb of Venus, let the letter I be set in twice, indicating the Icosahedron to be inscribed in the annual orb but circumscribed about the orb of Venus. Finally, in the fifth space, that is, between the orbs of Venus and Mercury, let the letter O be inscribed twice, indicating the Octahedron to be inscribed in the orb of Venus but circumscribed about the orb of Mercury. Or else let the names be written out in full: in the first interval, of the Cube; in the second, of the Tetrahedron; in the 3rd, of the Dodecahedron; in the 4th, of the Icosahedron; in the 5th, of the Octahedron. And to aid the memory, the following distich will not be useless:

Cappa surrounds Jupiter; Tau, Mars; Delta, the Elements; Iota surrounds Venus; and Omicron, Mercury.

Diagram. In the right column, within the sentence that introduces it: Kepler's scheme of the planetary orbs and the five regular solids. A rayed disc at the centre carries the letter A; around it stand seven pairs of concentric circles, the orbs with their thicknesses. The planetary signs stand on the vertical axis above the centre, and the letters of the solids along the horizontal axis on either side, as the text prescribes; the names of the solids stand on the vertical axis below the centre.

- A (centre, in the rayed disc): the centre of the annual orb
- ♄, ♃, ♂ (upper axis, outermost first): Saturn, Jupiter, Mars
- ● (upper axis, between the circles of Mars and Venus): the small black globe marking the Great Orb of the Earth
- ♀, ☿ (upper axis, next to the centre): Venus, Mercury
- C, T, D, I, O (horizontal axis left of the centre, outermost first) and O, I, D, T, C (right of the centre, innermost first): Cube, Tetrahedron, Dodecahedron, Icosahedron, Octahedron
- oct. (lower axis, innermost): Octahedron
- icof. (lower axis): Icosahedron
- ● (lower axis, below "icof."): the small black globe marking the Great Orb of the Earth
- Dode[[c/i]]. (lower axis): Dodecahedron [?]
- Tetraëdr. (lower axis): Tetrahedron

• Cubus. (lower axis, outermost): Cube provided you remember that *Cappa*, that is C, signifies the Cube; *Tau*, that is T, the Tetrahedron; *Delta*, that is D, the Dodecahedron; *Iota*, namely I, the Icosahedron; and *Omicron*, that is O, the Octahedron.

XXIII. Now Kepler supposes in the *Epitome*, p. 455, on the strength of Astronomical observations and the demonstrations of Copernicus, that, relative to the distance of the Earth from the Sun, or to the semidiameter of the great orb, the distance of Saturn is about tenfold; that of Jupiter fivefold; that of Mars one and a half times; that of Venus subsesquitertial [that is, three-quarters]; and that of Mercury about one-third. Thus the diameter of the orb of Saturn is less than double that of its neighbour, the orb of Jupiter; Jupiter's is triple that of Mars; and Mars's is one and a half times that of the terrestrial orb described about the Sun. The terrestrial orb, in turn, is more than four-thirds of Venus's; and Venus's is five-thirds, or eight-fifths, of Mercury's — though he adds that the proportions of the distances are not the same in every part of the orbit but differ from part to part, especially in Mars and in Mercury. From p. 468 of the same *Epitome*, together with chapter 14 of the *Mysterium Cosmographicum*, the following numbers are gathered. The former signify the proportion of the semidiameter of the orb inscribed in a given Regular body, the semidiameter of the orb circumscribed about the same Regular body being set at 100,000 parts; the latter signify the proportion of the same semidiameters as they come out of the Copernican hypothesis. So from setting them side by side, or comparing them, it may appear how nearly the Copernican measures approach the measures of the intervals required for the regular bodies to be inscribed, in the order already mentioned, in the concave of the orb of the higher Planet, or circumscribed about the convex of the lower.

Of which parts the semidiameter of the circumscribed Orb is 100000, of such parts the semidiameter of the Orb inscribed in the	ought to be	Of which parts the semidiameter of the Concave is	Of such parts the semidiameter of the Convex is, by Copernicus	From Copernicus, Book 5, chapter
Cube	57735	♄ 100000	♃ 63500	9
Tetrahedron	33333	♃ 100000	♂ 33333	14
Dodecahedron	79465	♂ 100000	Earth 75700	19
Icosahedron	79465	Earth 100000	♀ 79500	21 22
Octahedron	57735	♀ 100000	☿ 72300	27
Square in the Octahedron	70711			

I explain the small table. If a circle, or rather an orb, is made whose semidiameter is 100,000 parts, and a Cube is inscribed in it, and in turn another orb is inscribed in this cube, the semidiameter of this orb will be 57,735 of those parts. Again, if the semidiameter of this second orb is divided into 100,000 equal parts, and a Tetrahedron is inscribed in it, and a third orb is inscribed in this Tetrahedron, the semidiameter of this orb will be 33,333 of those parts; and so for the rest.

[Margin: Kepler's philosopheme on the intervals of the Planets and the Regular bodies.] XXIV. With these things premised, Kepler philosophizes as follows. In the Ptolemaic hypothesis the distances of the Planets from the centre of the Earth and of the universe are so arranged that nothing lies between the lowest, or least, distance of Saturn and the highest, or greatest, of Jupiter; rather, the concavity of the heaven of Saturn touches the convex surface of the heaven of Jupiter immediately, and so for the rest. This is surely for no other reason than that there may be no void between the heavens that does not belong to the dominion and jurisdiction of some Planet, being occupied at least by its Epicycle, if not by the body of the star itself; but no Geometrical beauty shines out in this, to which God might be said to have looked. In the hypothesis of Copernicus, by contrast, between the concave of the higher Planet and the convex of the lower there lies a space that is not necessarily occupied by the body of the Planet, nor by any Epicycle of it, nor by any other orb. And these spaces are so interposed that three simple, or primary, Regular bodies can be inscribed between the heavens of the three superior Planets — namely the Cube in the concave of Saturn, the Tetrahedron in the concave of Jupiter, and the Dodecahedron in the concave of Mars — while the two remaining, secondary, figures can be inscribed: the Icosahedron in the concave of the Annual orb, and in the concave of Venus the Octahedron, which can be circumscribed about the convex of Mercury. These things, I say, can be done exactly as regards Mars and Venus, and almost exactly as regards the Earth: for the number required is 79,465, and Copernicus has 79,500. Nor is Mercury enormously out, if in the middle of the Octahedron you inscribe a square formed by its four middle sides: the circle inscribed in this square will have a semidiameter of 70,711 parts, of which the radius of the orb inscribed in the Octahedron is 100,000, while the Copernican measures supply 72,300 parts. Jupiter alone departs much from what is required: for the radius of the orb inscribed in the cube ought to be 57,735, but from Copernicus it is 63,500. Yet although it departs, it is nearer to the measure of this body than to that of any other. Such great analogy and nearness of the numbers, therefore, cannot be said to have been fortuitous in the mind and Idea of God the Creator; and if those numbers are corrected somewhat according to these ideal and archetypal ratios (preserving, however, the ratios which the harmonic proportions of the motions require according to the six musical voices), the most beautiful analogies arise, and a reason is given a priori why six primary Planets were created by God, why there is so great an interval between the concave of the higher heaven and the convex of the lower, and why the three primary Regular bodies correspond in order to the three superior Planets. But such analogies and causes cannot be given a priori in any hypothesis of the Earth at rest in the middle of the universe, and much less in the Ptolemaic. Therefore the Copernican hypothesis is to be preferred (although Copernicus was unaware of his own riches and did not see these analogies); and accordingly the Sun is to be placed in the centre of the Universe, never moved from it, and the Earth, mobile yearly, between Mars

and Venus. And here now is the argument coming into its proper form of its own accord, which I am pleased to set out again distinctly.

[Margin: Argument 10 reduced to Form.] XXV. *That Hypothesis is to be preferred to the others in which alone, or most of all, a reason is given a priori, through Geometrical and Harmonic proportions — and those the most beautiful — both of the number of the Planets and of the interval between the Planetary heavens. But such is the Hypothesis of Copernicus, and it requires the Sun to be immobile near the centre of the world, and the Earth to be mobile with an annual motion between the orbs of Mars and Venus. Therefore the Hypothesis of Copernicus is to be preferred to the others, and the Sun must be set immobile near the centre of the world, and the Earth, mobile with an annual motion, between the orbs of Mars and Venus.* The MAJOR does not seem open to doubt, except from someone who would deny what very many wise men have confessed — that God, in the structure of this visible world, looked to the most excellent Ideas of the intelligible world, which He had from eternity in His divine intellect and expressed by speaking His Word, according to that line of Boethius:

…. He, most beautiful himself, bearing the beautiful World in his mind, and forming it in a like image:

or who would deny what was said by Plato in the *Timaeus*, in the *Epinomis* and in the books of the *Republic*, and indeed before him by Pythagoras, and received with such applause by all the centuries — namely, that God, in founding and preserving the World, was a Geometer and a Harmost; or who would dare to deny what the sacred scriptures testify of God, Wisdom 11: *You have disposed all things in measure, and number, and weight*. As for the concord and harmony of the heavens, that will be clear from the same divine scriptures, Job 38, and from what is to be said below in its proper places. The MINOR seems to have been sufficiently proved by Kepler from what was said from number 20 to 25.

[Margin: 1st Reply.] I reply, however, 1. by distinguishing the Major and denying it: if the number of the Planets commonly received by the wise, and evident to sense itself, is not retained; if those proportions do not agree, again and again, with certain observations of the celestial motions; if they are not suited to the end and effects which Divine providence set before itself in the structure and administration of the World; and finally if, in such a hypothesis, not even those proportions are adequately fo- und. I concede the Major, however, if the four conditions already mentioned are found in that hypothesis; but in that sense I deny the Minor. For, *first*, in the Copernican hypothesis the Sun — which was reckoned by all the wise (apart from a few followers of the Copernican opinion) to hold the chief place among the Planets and to govern the rest by its motion — is thrown down from the heaven into the centre of the Universe: it has no heaven at all, and is no longer a Planet, but stands outside the number of the Planets. The Moon, too, which was likewise always held to be among the primary Planets, is not counted among the primary Planets in this hypothesis, but is the Earth's attendant; while the Earth itself — indeed the whole sphere of the elements — is carried up into the heaven by a

truly monstrous Uranomorphosis, and becomes a primary Planet. So it comes about that the two great Luminaries are not counted in the number of the Planets, whose cause is being sought here; and so the two Lights of the world are plucked out of that number like a pair of eyes; and that most celebrated septenary of the Planets and of the Strings, made illustrious by so many other analogies and conditions, as I indicated in Book 7, Section 1, chapter 1, perishes in our hands. So if Kepler had so robust a stomach that he could digest the striking of the Moon and the Sun from the roll of the seven Planets, let him not take it ill if someone says that the analogy of a few regular bodies with the intervals of some of the Planets was neglected, in the structure of the world, by the primary order of the divine Ideas. For it is much more evident that the Moon and the Sun are primary Planets, both in the measuring of Times and in the effects of nature, and that the Earth does not move, is not a Planet, and deserves the name neither of a star nor of a celestial body, than that the intervals of the Planetary heavens are taken from the regular bodies.

[Margin: 2nd Reply.] *Secondly*: neither the Prutenic tables, built on the Copernican hypothesis, nor the Copernico-Tychonic Rudolphine tables are such as to agree perpetually with the celestial observations; on the contrary, they stray from them again and again, and in the chief Phenomena at that, namely Eclipses, as is clear from what was said in Book 5 and is by now well established among the Astronomers of this age. And as for what concerns the apparent magnitude of Mars and the proportions between its bulk and its intervals, we showed sufficiently in Book 7, Section 6, chapter 10, scholia 1 and 3 taken together, that Kepler erred and conflicts with manifest observations of the diameter of Mars.

[Margin: 3rd Reply.] *Thirdly*: those purely Geometrical proportions derived from the five regular bodies do not seem of themselves suited to the ends and effects which God willed, in nature, to depend on the intervals and motions of the Planets; and I say the same of the Harmonic ones. For the excellence of the regular bodies does not consist in the proportions of the diameters of the inscribed or circumscribed circle, but in the very character of bodies bounded by such faces. The heavens of the Planets, however, do not act on these lower things by reason of their corpulence so bounded — especially since, once the fluidity of the heavens is granted, the heaven of the Planets is in fact a single one, and so that real distinction of heavens and of regular bodies perishes — but by means of the bodies of the Planets, their light, and the qualities flowing from that light. These bodies are contained within the Zodiac; they do not act on the celestial spheres, which we mark off by reason alone, nor are they acted upon by them, nor, insofar as they are bodies, do they receive from them their force or the governance of their power — much less from bodies that can be inscribed between those spheres. And it is far more probable that the Geometry and Harmony of Divine wisdom in the structure of the World was much higher and nobler than to have followed that material beauty of dimensions, and of a harmony accommodated to our ears. But just as we say metaphorically that a

Prince geometrizes well, or that a Commonwealth is administered Musically, if he chooses and applies means suited to the end of public happiness, distributes offices, rewards, punishments and burdens according to the endowments and merits of each, and so tempers himself to the characters and customs of his subjects as to preserve peace and concord among them and with himself, as well as the due subordination of the lower to the higher: so too, and far more worthily, must we think of God in the government of this world, even as regards natural effects. [Margin: How the Geometry of God is to be understood.] Thus in Wisdom 11, where the discourse concerned the governance by which God had so inflicted punishments on certain impious men that by the very things by which one had sinned he was punished, and so they were corrected — when otherwise He could have exterminated them at once in many ways by exercising His Omnipotence, as anyone who reads that chapter will see — for that reason, after the words *But you have disposed all things in measure, and number, and weight*, there follows at once: *For great power always remains with you alone, and who will resist the strength of your arm? For as the small weight that tips the balance, so is the world before you, and as a drop of the morning dew that comes down upon the earth. But you have mercy on all, O Lord, etc.* So too in chapter 32 of Ecclesiasticus it is said, *They have made you ruler*, and shortly after, *do not hinder the music*; and what music the discourse there concerns is made plain, namely the prudent and fitting government of subjects. But if it nonetheless pleases anyone to bind God to the compass and square of material Geometry, I should gladly ask Kepler why He did not keep the laws of any regular figures in the distribution of the Fixed stars, in the spots of the Moon, and in the surfaces of the Seas and of the great continents? Why, in organizing the body of an animal — especially of man, in whom we so greatly admire the depth of divine Wisdom — did He not conform the magnitudes, figures and intervals of the brain, the heart, the liver and the other parts to the properties of the regular bodies? Is it because these are not spherical bodies, nor destined for circular motion? But neither are the orbits or paths of the Planets spheres, or a great part of spheres, except among those who have introduced solid orbs (which Kepler rejects) without any necessity, and indeed against the protests of the observers of the heavens. It will doubtless be answered more truly that figures of this kind are not of themselves suited to the functions and effects which God and nature preordained in these works.

[Margin: 4th Reply.] *Fourthly* and finally: the proportions taken from the Regular bodies are not found adequately in the Copernican or the Keplerian hypothesis. For neither the size of the interval between Saturn and the Fixed stars, nor that between Mercury and the Sun, nor the thickness of the heaven of Saturn, is determined from them; and of the remaining five intervals there are only two that come very near, or near, to the proportions owed to the bodies to be inscribed, namely the intervals of Mars and of Venus. The rest differ greatly — not only between Jupiter and Saturn, and between Venus and Mercury, as Kepler admits in the places cited, granted that he begs a remedy for them from

far off, but also that of the Earth, if the space of the Lunar heaven carried round with it must be confined within the orbit of the Earth. And so in the *Mysterium Cosmographicum*, chapter 16, he grants that the little orb of the Moon stands out above the orb of the Earth like a gem above a ring, or like the orbs of the Satellites of Jupiter above Jupiter's orbit, and is not hindered by the spaces of the regular bodies, because the heavens are not adamantine or solid. Of Mercury I have already said above that, if one is to come near the measures of the Copernican hypothesis, its interval must be determined not by the Octahedron but by the square inscribed in that octahedron. Therefore, unless corrections of the measures are scraped together by a violent search through various windings, the analogy of the Planetary intervals with the capacity of the regular bodies shines out only in two, or at most in three, intervals.

[Margin: 2nd Reply.] XXVI. I reply, therefore, 2. by granting the Major and denying the Minor as to both its parts. That the proportions of the said bodies are not found exactly and adequately in the Copernican hypothesis, and that no reason for the true number of the Planets is given in it, is clear from what was said in the first reply, in the paragraphs *First* and *Fourthly*. And Kepler admitted, in Book 5 of the *Harmonics*, chapter 3, that the Harmonic proportions can be found in the Tychonic hypothesis too, or in others like it, and in the same place that the Tychonic observations conflict with that exact configuration of the regular bodies. For when he had said *that the Earth is one of the Planets and is carried among the stars around an immobile Sun*, he nevertheless at once added: *Let those, therefore, who are offended by the novelty of this science know that these harmonic speculations hold their place in the hypotheses of Tycho Brahe as well, because that Author has in common with Copernicus everything else that concerns the disposition of the bodies and the tempering of the motions.* And on the following page: *As regards the proportion of the Planetary orbits, it is indeed always such between each two neighbouring orbits that it readily appears that each of them approaches the single proportion of the orbs of one of the five solid figures, namely of the circumscribed orb of the figure to the inscribed orb; and yet it is not wholly equal, as I once ventured, concerning a finally perfected Astrono- my, to promise. For after completing the demonstration of the intervals from Brahe's observations, I found this, etc.* He then goes on to explain at greater length the shortfall or excess of the intervals that come out of the Tychonic observations, below or above the measures owed to the inscription of the regular bodies, and concludes: *In short, the Cube and the Octahedron, a pair, penetrate their planetary orbs somewhat; the Dodecahedron and the Icosahedron, a pair, do not quite reach theirs. The Tetrahedron touches both precisely: there it is less, there more, here equal, in the intervals of the Planets. From this it is clear that the very proportions of the intervals of the Planets from the Sun are not taken from the regular figures alone.* Read the rest in his own text. In the same Book 5 of the *Harmonics*, chapter 9, proposition 49, he bursts out into this exclamation: *It was good that the solid figures should yield, in the generation of the intervals, to the Harmonic ratios.* Since, therefore, in neither hypothesis — that of Copernicus, namely, or that of Tycho — are the intervals

of the Planets taken from the regular bodies taken exactly; and since it is the Harmonic proportions that should chiefly be considered (as Kepler at any rate holds), and these find a place in the Tychonic hypothesis as well (and, I add, in ours too, which in these respects is sufficiently equivalent to the Tychonic): we are not compelled by these proportions to prefer the annual motion of the Earth to the annual motion of the Sun, or the rest of the Sun to the immobility of the Earth.

CAPVT IX.

Chapter IX.

Proponuntur, & Diſſoluuntur Quinque Argumenta pro Annuo Terræ Motu, ex Planetarum Motibus & inſtrumentis motuum deſumpta.

Five Arguments for the Annual Motion of the Earth, taken from the Motions of the Planets and from the instruments of their motions, are Proposed and Resolved.

I. Although in the preceding Chapter mention was made of the motion of the Planets in certain arguments, chiefly the 2nd and the 4th, the arguments there were nevertheless not drawn from their motion itself, taken immediately, as will be done in this chapter. Let this be said to keep the titles sufficiently distinct.

I. Argumentum à Superfluitate motuum trium Superiorum Planetarum per Epicyclos, & duum Inferiorum per proprios Eccentricos, Sublata per vnicum ac ſimplicem Telluris Motum Annuum.

I. The Argument from the Superfluity of the motions — of the three Superior Planets through Epicycles, and of the two Inferior ones through their own Eccentrics — a superfluity removed by a single and simple Annual Motion of the Earth.

II. Here surely, if anywhere, the Copernicans seem with good reason to triumph, and with an irresistible battering-ram to shake the Ptolemaic system, or others akin to it, and all but bring it down. And to this point likewise tend those words of Copernicus in Book 1, chapter 10. For after he had said, *Whatever appears concerning the motion of the Sun is verified rather by the mobility of the earth*, he added shortly afterwards: *Which I think easier to concede than to have the understanding distracted into an almost infinite multitude of orbs, as those who have kept the earth in the middle of the world have been forced to do. But the sagacity of nature is rather to be followed, which, just as it has taken the greatest care not to have produced anything superfluous or useless, so has rather often endowed one thing with many effects.* [Margin: The annual orb of the Earth commended, from Copernicus.] Adhering to this, Rheticus in his *Narratio prima* warns

Astronomers that, just as Galen insists in Book 10 of *De usu partium* [*On the Usefulness of the Parts*] — namely that nature does nothing superfluous, and does not trouble to search out through many means what it can obtain by one or two — so they too, in framing hypotheses, should avoid superfluities. [Margin: And from Rheticus.] Then he infers: *Therefore, since we saw that by this single motion of the earth almost infinite appearances are satisfied, should we not attribute to God, the founder of nature, that skill which we see ordinary clockmakers possess? For they take the greatest care not to insert into the instrument any little wheel that is either superfluous or whose function another could supply more conveniently with its position slightly changed.* And explaining in particular the advantages that arise from the single motion of the Earth through its annual orb, he says: *To this is added that the motion of the earth in its orb produces the arguments of all the Planets except the Moon — that is, the Anomaly of the orb, or second inequality, which the Alphonsines call the Argument — and that it alone seems to be the cause of all the variation of motion, which appears, namely, in the three superior ones from the Sun, but in Venus and Mercury around the Sun.* And again he says that from this motion of the earth it follows *that all the variation of the apparent motion of the Planets, which seems to occur in them* [Greek: παρὰ τοὺς πρὸς τὸν ἥλιον σχηματισμοὺς (para tous pros ton hēlion schēmatismous, "according to their configurations with respect to the Sun")], *comes about through the annual motion of the earth in the great orb; and that the Planets in truth proceed with only the one remaining inequality, which is observed with respect to the parts of the Zodiac.* Ptolemy, then, and almost all the others down to Tycho, set out the first inequality of the motions in the Zodiac, in the five lesser Planets, by means of Eccentrics, and the second — which arises from their varying recession, or approach, and configuration with respect to the Sun — by Epicycles, or by orbs equivalent to Epicycles, but multiplied. Copernicus, by contrast, sets it out and saves it by a single annual orb of the Earth approaching the Planets and receding from them, and so achieves what in the Ptolemaic system three Epicycles of the superior Planets and two distinct Eccentrics of the Inferior Planets must achieve.

III. This, moreover, is what Kepler so insistently urges: first in the *Mysterium Cosmographicum*, chapter 1, where he says: [Margin: The same orb and motion commended, from Kepler.] *This orb and motion of the Earth, then, provides these advantages: that we do not need three eccentrics in the customary hypotheses, namely those of the Sun, of Venus and of Mercury. For because the Earth is carried round about these three Planets, the Earth-dwellers think that those three are carried round about themselves, who are immobile. And if there were more stars within the orb of the Earth, they would ascribe this motion to more as well. With this orb posited, the three great epicycles of Saturn, Jupiter and Mars also fall, together with their motions.* And then more explicitly in the *Epitome of Copernican Astronomy*, Book 4, page 542, where he admits indeed that those great Ptolemaic Epicycles were removed by Tycho too, yet says that Tycho left in the world the same thing that was effected by them: *namely, that any Planet, besides the motion that is truly to be granted to it, is still moved in addition by the very motion of the Sun, mixing the two into one; from*

which measure, since there are no solid orbs, most intricate spirals are produced in the space of the world. (Of this intricacy I displayed a diagram and a specimen, from Kepler himself, in Book 7, Section 1, at the end of the last chapter.) *Copernicus, by contrast, entirely strips the five planets of this extraneous motion of the Sun by a single simple motion of the centre of the earth, and brings it about that the centres of the six primary planets — of the Earth, namely, and of the other five — each describe in the space of the world a single orbit, simple and perpetually like itself, or a line very close to a circle.* So he says on page 543, alluding to the Elliptical orbit he himself introduced into Astronomy. Further, Lansbergen, in tract 4 of the *Apologia* for the motion of the earth, considering the five already-mentioned extraneous motions of the Planets removed by the annual motion of the Earth, and the eight diurnal motions of the eight spheres erased by the diurnal motion of the Earth, says: *By the Earth's motion is done what would have had to be accomplished by thirteen motions of the stars.* And he presses those physical axioms: *Nature proceeds in order, abhors superfluities, does nothing in vain.*

IV. But since Kepler knew that the already-mentioned motions of the Planets, which seem to us multiple, could be attributed to Intelligences leading the Planets round along a single spiral line, [Margin: A reply anticipated, from Kepler.] he met this reply in Book 4 of the *Epitome of Copernican Astronomy*, page 546, he said that the condition of the moving souls would be very hard, and harder still that of the Intelligences, when they are ordered to attend to very many things, so as to carry the planet in order with two motions distinct in every respect and mixed with each other; but if the Sun rests and the earth moves, the motion of each Planet is single, and it can be effected by corporeal magnetic powers, by a single revolution of the body of the Sun about its own centre, *and there is no need at all, anywhere, of the safeguard of a mind*, he says. And he refers the Reader to the *Commentaries on Mars*, where he teaches by what means the Sun, through a magnetic power diffused and emitted from itself through its light in every direction, grasps the Planets and whirls them round in a circle. But let us now come to the formula of the argument.

V. [Margin: The argument in form.] *That hypothesis is to be preferred to the others which accomplishes with fewer and simpler motions what the others cannot accomplish except with more, and more composite, motions. But the Hypothesis in which the Earth is moved through an annual orb is of this kind. Therefore it is to be preferred to the others.* The MAJOR is clear from the axioms already adduced so many times; for it is most widely accepted that God and Nature, and indeed art too, are not accustomed to bring about through more what can be done through fewer, and that means and instruments — indeed, generally, any entities at all — are not to be multiplied without necessity, or without greater utility. The MINOR has already been proved, since it has already been shown that from the annual motion of the Earth there follows that apparent second motion in the lesser Planets which represents the second inequality, called the annual, or the one tempered to the apparent motion of the Sun; and so that

what would otherwise have to be done by Epicycles, or by distinct Eccentrics, is done by a single annual orb.

[Margin: 1st Reply.] I reply, 1.: if it accomplishes the phenomena that are already evident to sense, and in a way no more absurd than is the composition of motions, I concede the Major; if it does otherwise, I deny the Major, and accordingly I deny the Minor. For the hypothesis in which the Earth is moved through an annual orb does not accomplish the phenomena evident to sense. Rather, it destroys and inverts those that are evident to common sense — such as the motion of the Sun, and the harmony of the Planets tempered to the Sun — and destroys them, moreover, without any necessity, and introduces a motion from which the intellect, relying on sense (as is fitting in Physics), recoils more than from a multiplicity of motions. [Margin: How far the fallibility of the senses is to be admitted.] Nor is there any reason to thrust at us that oft-repeated refrain, that the senses are deceptive and that this dispute is not to be decided from their estimation. For the answer is that they are deceptive neither always nor for the most part, and that their deception is detected when reasoning is applied — but reasoning that itself relies on more certain sensations. Otherwise, for as long as they are not caught erring in this way in some particular object, we must abide by them, and their estimation stands in possession as regards what our assent requires. For because some eyes are dim-sighted, or ours sometimes run with rheum, or an animal is sometimes sick, must we say that all eyes are dim-sighted? or that ours always suffer from rheum, or that an animal is never healthy? Moreover, does not the intellect itself err in many matters that do not depend immediately on sense, in such a way that the error cannot be attributed to the deception of the senses? You will certainly say so; for about the same sensible thing, and the same experience had through the senses — about the Rainbow, say, or the tide of the Sea — different people hold different and contradictory opinions, some one of which must be false. Is the intellect, then, not to be trusted either? Let those who are of this kind see to it, then, that they do not undermine the foundations of all the sciences.

To the proof of the Major I reply that those axioms are not to be taken absolutely, or in a purely arithmetical sense — as though God and Nature, or even Art, always aimed at unity, or at the number that comes as close as possible to unity — but relatively to the end set before them, and taken not only as regards the substance of the thing to be made, but also as regards the accidents befitting it for its being well, or better, in its own order. Nature could indeed have made and preserved Plants and Animals with fewer fibres, little veins, little nerves, little skins, little membranes, hairs, leaves, little roots, etc., but not so well and so fittingly. God too could have filled this world with fewer stars, with narrower tracts of Seas and Lands, and with a smaller number of insects, reptiles, fishes, birds and quadrupeds; but he would not have attained the end he attains as things are, nor in the way he attains it. And since Rheticus chose the comparison of Clocks: if someone were to add more wheels to some clock, so that the same hour was struck not once but twice, or so that, with

two distinct bells, the hours were struck on the larger and more sonorous one and the quarters of the hours on the smaller, he would be using wheels that, considering his end, are not superfluous but necessary. So in the case proposed: if God willed to display not the mere appearance of the motions of the Sun, and of the Planets that look to the Sun in their motion, but the real motion itself of the Sun and of the Planets — that motion now so quickened that they become ever more easterly, now slow, so that they seem neither to advance nor to go back, now finally retrograde against the order of the signs — and willed a variety of many effects to depend on this real variety, he is not to be thought to have introduced superfluous motions. I will give another example. A musical concert could certainly be so arranged that, with fewer voices and instruments but with a polyphonous Echo applied, there would seem to be more voices and more instruments; but if someone sets before himself not this mere appearance but a real multiplicity of voices and instruments, so as to produce the concert in that way, he will in no way be blameworthy, even if he could have used that Echo with equal ease.

[Margin: 2nd Reply.] I reply, 2.: if that hypothesis multiplies, in another kind, more motions, and more composite ones, than the other hypotheses do, I deny the Major; if it does not multiply them, let the Major pass. But in this sense the Minor is denied. For although the hypothesis that moves the Earth with an annual motion seems not to multiply motions, inasmuch as by this single motion it accomplishes five motions of the lesser Planets, yet in truth, looking more deeply, it multiplies other motions no less — indeed, more composite ones. For it multiplies the motion of the Moon: it makes the Moon, besides its monthly motion around the Earth, also move with an annual motion together with the Earth's centre, so that in this respect the Moon must perform not only the Moon's office but the Sun's. Next, it multiplies the same annual motion in the Earth, in the Water, and in the whole Elementary sphere; so that if the elements are four, the motions of these and of the Moon are five, and distinct, indeed, with the same distinction as the mobile bodies themselves. Besides, since not only the animals standing on the Earth but also the birds flying in the air, and all the meteorological bodies that hang or move in the air or in the fire (if there is such a thing), must follow the annual motion of the Earth, or of the Earth's centre, this number of motions is multiplied as many times as there are subjects moved by such a motion. Finally, since it is certain that the physical and astronomical phenomena cannot be saved unless a diurnal motion is added to the annual motion of the Earth — as the Copernicans freely admit — it is necessary to add the diurnal motion not only to the Earth but to all terrestrial and watery bodies, however far separated from the water and the earth, and, besides the rectilinear motion of the Elementary bodies, to introduce a curvilinear one made along a longer path. [Margin: Note the true economy of motions in the hypothesis of the Earth at rest.] All things considered, therefore, this annual motion of the Earth brings with it far more motions, both in number and in kind, than that hypothesis in which, by a wonderful economy of nature,

the phenomena and the real effects of these vicissitudes are saved: through the immobility of the Earth and of the Elements as regards their whole bodies, and a most simple rectilinear motion of the parts — and that not perpetual, but only in the cases in which the parts of the Elements are outside their natural place; and in the heaven through a single spiral line in each Planet, always towards the West, but with spirals now higher, now lower, now widened out, now narrower, led round by the Intelligences sometimes faster, sometimes slower.

[Margin: 3rd Reply.] One could therefore reply, 3., by turning back the argument drawn from the multiplicity of motions; it is enough to have pointed this out. I am pleased to transcribe here the words of Tycho from volume 1 of the *Progymnasmata*, page 661, where he says: *I admit indeed that the circuits of the five Planets which the ancients attributed to Epicycles are in this way dispatched very neatly, and with less trouble, in the Earth alone; that many mathematical absurdities committed by the Ancients, and an enormous incoherence, are guarded against by Copernicus; and that the celestial appearances are satisfied somewhat more accurately. Nevertheless, since this can also be accomplished in another way, as we have done in our hypothesis, equally well, if not more correctly, to what end is there need to fashion without good cause, out of the Earth, an opaque, gross and sluggish body, a kind of Star revolved even more multiply than the others — subject, that is, to a triple motion — not only against all Physical truth, but also with the authority of Sacred scripture opposing it, which ought to be paramount?*

II. Argumentum ab Imperfectione motuum cæleſtium, ſi reipſa tales ſint, quales apparent, Sublata, & meræ apparentiæ attributa, Redditaque à priori cauſa per annuum motum Terræ.

II. The Argument from the Imperfection of the celestial motions, if they are in reality such as they appear — an imperfection removed and attributed to mere appearance, and its cause given a priori through the annual motion of the Earth.

VI. The greater the variety and inconstancy in the celestial motions, the greater the imperfection they seem to suffer from. Now in the five lesser Planets there appears a manifold variety and inconstancy of motions. For, *first*, it is established that they sometimes cling to the same place of the sphere of the Fixed stars in such a way that they seem to stand still, their course checked; and sometimes, as if led by repentance of their direct motion, to Recede against the order of the signs and, like Penelope's web unwoven, to cancel or obliterate the motion by which they had previously advanced in the order of the signs. But Copernicus removed all this imperfection in Book 5, chapters 3, 35 and 36. For once an annual motion of the Earth is posited below the orbs of Saturn, Jupiter and Mars but above the orbs of Venus and Mercury, and in such a way that in their periodic motion beneath the Zodiac the three superior Planets are slower than the Earth, while Venus and Mercury are swifter than the Earth, the Earth must so approach these planets and recede from them that they seem

sometimes to advance, sometimes to stand still, and sometimes to go backward. The cause of these imperfections, therefore, is not physically in their motion — for they always advance — but is a mere appearance, and a purely optical cause, owing to the motion of commutation by which the Earth is carried round in a circle every year. For where the additive [adiectiuus] motion of the Planet is equal to the subtractive [ablatiuus] motion of commutation, the Planet will seem to stand still; where the subtractive motion of the Planet is greater than the additive motion of commutation, it will seem to go back; and where, finally, the subtractive motion of the Planet is less than the motion of commutation, it will seem to advance directly. We too explained this in Book 7, Section 5, chapter 4, with diagrams appended. [Margin: Kepler's doctrine of the Retrogradation of the Planets.] Comparing this hypothesis with the Ptolemaic, Kepler says in chapter 1 of the *Mysterium Cosmographicum*: *For it could have been asked of Ptolemy why the five Planets become Retrograde, but not the Luminaries? The answer, first concerning the Sun, is: because it is at rest; from which it comes about that the motion of the Earth, which is always direct, seems to be in the Sun itself, purely and undisturbed, only through the opposite part of the heaven. Concerning the Moon: because the annual motion of the Earth is truly common to its heaven together with the Earth; and two things that have the same motion in every respect seem to be at rest relative to each other. Hence the motion of the Earth is not perceived in the Moon, as it is in the other Planets. Concerning the Superior ones, Saturn, Jupiter and Mars, the answer is: because they themselves are slower than the Earth, and because that circle and motion of the earth is thought to be in them. Therefore, just as to those who looked out from the globe of Saturn the Earth would seem sometimes to advance, while it went through the half of the circle above the Sun; sometimes to go back, while it went through the other half, nearly; and to stand still at two points, namely those that bound the Direct and the Retrograde course: so it is necessary that to us, looking out from the Earth, Saturn should seem to be rolled towards the opposite parts, and so to go back at the time when, to one watching from Saturn, the earth would seem to go back; and Saturn to advance when the Earth advances, etc.* And he continues, saying: *The Inferior ones, Venus and Mercury, seem to go back for this reason, that they are swifter; so that, just as if the Earth stood unmoved, Venus, running in the more remote part of its circle, describes a path entirely contrary to the one it completes in the part of its circle near the Earth.* [Margin: Galileo's opinion on the cause of Retrogradations.] To this is added Salviati, or rather Galileo, who in dialogue 3 on the System of the World, page 252 of the Latin version, after saying, *In the Ptolemaic system there are diseases, and in the Copernican the remedies*, added a little later: *But what shall we say of the apparent motions of the Planets, so unequal that not only are they now swift and presently slower, but sometimes they even become entirely stationary, and even retrograde over a long space? To save this appearance Ptolemy introduced very great Epicycles, fitted to the individual Planets, with some rules of anomalies, or of incongruous motions, all of which are removed by a single, most simple motion of the earth.* Then, after some intervening words, Sagredo replies in the same place that these retrograde

and stationary motions have always seemed improbable to him, and that he therefore wishes it to be explained how the system of Copernicus excuses them; which Salviati shortly does, and so do we, as I said, in Book 7, Section 5, chapter 4, number 3. [Margin: Gassendi's concurrence.] The same cause — why the Luminaries do not seem to go back, while the other Planets do — is elegantly pursued by Gassendi in Letter 2, *De motu impresso*, page 145.

VII. [Margin: The 2nd imperfection removed by the annual motion of the Earth.] The *second* imperfection, or inequality, which seems to be in the motion of the five lesser Planets, and which is removed by transferring the true cause of such a phenomenon to the annual motion of the Earth, is the one Copernicus hinted at towards the end of Book 1, chapter 10, thus: *For from this one who contemplates not idly may notice why a greater progression and a lesser regression appears in Jupiter than in Saturn, and a lesser one than in Mars; and again a greater in Venus than in Mercury. And why such a reciprocation appears more frequently in Saturn than in Jupiter; more rarely still in Mars and in Venus than in Mercury.* For we have already shown in Book 7, Section 5, chapter 2, that the arc of direction of Saturn is less than that of Jupiter, and Jupiter's less than that of Mars, and greater in Venus than in Mercury, adding a twin table of this diversity; and in the same place, number 5, proposition 2, we added the cause why the Stations and Retrogradations of Saturn recur more often than those of Jupiter, and Jupiter's than those of Mars, and Mercury's than those of Venus. Now since Ptolemy tried to set these out by assigning a greater Epicycle to Mars than to Jupiter, to Jupiter than to Saturn, and to Venus than to Mercury, he seems to have multiplied motions and instruments, and yet not to have given the true cause of these inequalities: for the greater Eccentric of Saturn would seem to demand a greater Epicycle too. [Margin: The 3rd imperfection removed by the annual motion.] From this arises the *Third* imperfection in the Ptolemaic hypothesis, one removed by Copernicus. Hence that reproach of Kepler's in chapter 1 of the *Mysterium*: *So it could have been asked (but with Ptolemy answering nothing) why in great orbs there are such small Epicycles, and in small orbs such huge ones: that is, why the* [Greek: προσθαφαίρεσις (prosthaphairesis, "prosthaphaeresis", the equation)] *of Mars is greater than Jupiter's, and Jupiter's greater than Saturn's? And why does Mercury not also have a greater one than Venus, since it is lower than Venus, given that of the other four the lower always has the greater? Here the answer is easy*: namely, in the hypothesis of Copernicus, from which he gives the cause of these vicissitudes. [Margin: Kepler's second commendation of the annual motion of the Earth.] For, of course, as each of the Superior planets is nearer to the annual orb of the Earth, so the annual orb has a greater proportion to it, and appears greater. Mars, therefore, as nearest to the Earth's orb, has in its Radius more parts — of which the Radius of the annual orb is 100,000 — than Jupiter has, and Jupiter more than Saturn; and therefore the prosthaphaeresis arising from this is greatest in Mars, moderate in Jupiter, least in Saturn. Moreover, what the ancients thought were Epicycles in Mercury and Venus are in truth, in the hypothesis of Copernicus, Eccentric Orbs; and to Mercury, as the swiftest,

belongs the smallest orb, smaller than Venus's. So he says. [Margin: The 4th imperfection removed by the motion of the Earth.] And he soon adds a *Fourth* imperfection, or necessity, in these Retrogradations, whose true cause only the hypothesis of Copernicus seems to provide. *Likewise*, he says, *the ancients wondered, not without reason, why the three superior ones are always lowest in their Epicycle at opposition with the Sun* (understand: and Retrograde) *and highest at conjunction: so that, if the Earth and the Sun and Mars are in the same line, why Mars cannot then be in any other place of its Epicycle than at the Perigee. In Copernicus the cause is easily given. For it is not Mars in an Epicycle but the Earth in its orb that causes this variation, etc.* [Margin: Kepler's 3rd commendation of the annual motion.] For Mars could have been moved in its Epicycle against the order of the signs, and so have turned out direct at opposition and retrograde at conjunction with the Sun; nor can the cause why this motion was not made in that way be given through the Epicycle: one merely falls back on the effect and on experience, a posteriori. But since Gassendi treated these arguments not inelegantly, and it is useful to press this argument home in various ways so that its force may be set out more clearly, I am pleased to repeat from him, in other words, what has been said so far.

VIII. [Margin: Gassendi's confirmation of the causes already mentioned.] And so Gassendi, in Letter 2 of *De motu impresso a motore translato*, page 145, argues thus for the annual motion of the Earth: *Next, to speak also of the three more remote ones, Mars, Jupiter and Saturn: what is the reason that they never appear retrograde except when they have the Earth interposed between themselves and the Sun? or why are they always retrograde when they have it interposed? Why is the Epicycle of Mars greater than the Epicycle of Jupiter, and this one greater than the Epicycle of Saturn?* And a little later: *Why is Mars so much swifter than Jupiter on its Eccentric, and yet so much slower on its Epicycle, and Jupiter, in the same proportion, than Saturn, and so on for the rest?* And he answers at once that this must necessarily appear so, as the Earth proceeds between the Sun and them; for although both they and the Earth always advance towards the East, *it nevertheless comes about that, because the Earth moves faster than they do, when, approaching from far off, it is about to pass close by them, or to interpose itself between them and the Sun, they appear now to proceed more slowly than before; and when it approaches as if in a straight line, they appear as if to stand still; and thereafter also to go backward, since the Earth, pressing on faster, gradually leaves them behind, so that the retrogression appears greatest when the Earth is nearest and has them directly opposite; and afterwards it appears gradually to decrease, until, as the Earth departs from them as if along a straight line, they seem once more as if to stand still. After the second station, however, they appear to proceed directly and ever more swiftly, because the Earth thereafter, as it is about to pass beyond the Sun, observes them advancing according to the series of the Signs — they who, in the opposite position, seemed to go against that same series. Hence, then, it is that they cannot appear retrograde except in opposition with the Sun, etc. Hence the reason why the Epicycle of Mars appears greater than the Epicycle of Jupiter: because, namely, on account of its greater nearness,*

the retrogradation in it begins to appear nearer and ends farther, etc. Hence the reason why Mars is retrograde only once in two years: since the Earth, proceeding only twice as fast, cannot overtake it except in double the time in which it completes its own period. Hence the reason why Jupiter runs its course every year and becomes retrograde, and that only one month later; because the Earth is twelve times swifter and, having once left it behind, always overtakes it in the thirteenth month. Hence the reason why Saturn too becomes retrograde every year, and that scarcely half a month later, because the Earth is thirty times swifter and, having departed from it, overtakes it again in the twelfth month and scarcely half a month besides. With these foundations laid, then, let us build the following argument upon them.

IX. [Margin: The 2nd argument in form.] *That hypothesis is to be preferred to the others in which alone the imperfections of the Stations and Retrogradations are not real but merely apparent, and through which alone a reason is given a priori both of the Stations and Retrogradations already mentioned and of the other diversities attached to them. But such is the hypothesis of the Earth proceeding annually between the three superior and the two inferior Planets. Therefore this hypothesis is to be preferred to the others.* [Margin: Proof of the Major.] The MAJOR is evident to any well-disposed intellect: for who would not grant that it is better that, if any imperfection occurs in celestial motion, it should be apparent rather than true and real? Who, likewise, would be so ἄλογος [Greek: ἄλογος (alogos, "irrational")] as to prefer always to stumble along a blind path in the darkness of that hypothesis which cannot give the causes of such appearances, rather than in the light of the one that can show them? [Margin: Proof of the Minor.] The MINOR has already been shown above by an induction made both from the Stations and Retrogradations themselves, taken in themselves, and from the diversities connected with them — of which kind are these: that these vicissitudes are more frequent in Saturn than in Jupiter, and in Jupiter than in Mars; likewise, that the arc of Direction of Saturn is of more degrees than that of Jupiter, and Jupiter's than that of Mars; likewise, that Saturn, whose Eccentric is greatest, has the smallest Epicycle, or proportion to the annual orb; and Mars, whose Eccentric is the smallest among the three superior ones, the greatest Epicycle, and Jupiter a middling one; and that the Equation of the second inequality is greatest in Mars, the lowest of the superior ones, and yet least in Mercury, the lowest, or innermost, of the inferior ones; again, why they are always retrograde in the position nearest the Earth and direct in the most remote, and why this could not have happened otherwise; finally, why the Luminaries are incapable of Station and Retrogradation. For of all these a simple and plain reason is given by the annual motion of the Earth, compared with the proper motion of each Planet beneath the Zodiac.

[Margin: 1st Reply.] I reply, 1.: by distinguishing the Major, and denying and conceding it under precisely the distinction with which I distinguished the Major of argument 1, set out in number 5 of this chapter; and in the same way to the Minor, just as if that reply had been inserted here word for word.

[Margin: 2nd Reply.] I reply, 2.: by conceding the first part of the Major, if apparent Station and Retrogradation in the Planets is an imperfection; and by denying it, if it is not an imperfection but a great perfection in their motion, considering the end to which that motion is ordered and the vicissitude of the effects that depend on them in sublunary nature. For who would say that in harmonic concords and in rhythmic dances there are imperfections in what they call *Pauses*, and in the retreats or returns of vocal phrases, of sounds, of dance-steps, etc.? Or, in Dialectical reasoning, in the progression from causes to effects and the regression from effects to the causes to be demonstrated?

[Margin: 3rd Reply.] I reply, 3.: granting the Major for the present, by denying the Minor. For it is one thing to give a cause that is, at first sight, single and simple — and so to repeat the first argument of this chapter, which has been answered sufficiently; it is another to give the cause of such appearances in this hypothesis alone. But all the hypotheses celebrated so far — whether Ptolemy's, or Magini's, or Tycho's, or Our own — give the cause of these Phenomena a priori, though not in the same way, nor in the way the Copernicans want. For what these accomplish by the motion of the Earth compared with the motion of the five lesser Planets beneath the Zodiac, others accomplish by the motion of the Sun compared with the motion of the same Planets (the Earth standing still), but through an Epicycle carried by an Eccentric, or through a Spiral, or through some other equivalent orb. And in the Ptolemaic system, indeed, the Planets in reality never stand still or go back in their orbs, if you place the eye at the centre of their Epicycles, but always advance in the order of the Signs: just like the Copernican Earth viewed from the Sun as from the centre of the annual orb — granted that, if the Earth too were viewed from elsewhere, it would seem beneath the Fixed stars sometimes to stand still, sometimes to go back. In the Tychonic hypothesis, moreover, as Kepler admits in Book 4 of the *Epitome*, pages 535 and 537, the absurdity of the Retrogradations is avoided if the Sun is laid down to be the centre of the Planetary system and to carry with it the centres of the orbs of the five lesser Planets; and in this way, likewise, Astronomy is freed from two superfluous Eccentrics, those of Mercury and Venus, and from three great Epicycles, those of Mars, Jupiter and Saturn. Therefore, if the cause of these appearances is the concurrence of motions — the comparison, that is, of the lesser Planets on the one side with the Sun or the Earth on the other — the annual motion of the Sun can be received among the a priori causes just as well as that of the Earth; for either one is sufficient to represent them, with this difference, however: that the motion of the Sun, being evident to sense, has already taken possession of the judgements of the greater number of the Wise. The Copernican sect, however, seems to be of too delicate a taste, since for it no motion — neither the Sun's nor any other, except the Earth's — has the savour of the genuine a priori cause of such phenomena; a savour sharpened by the simplicity of the annual motion of the Earth, which is greater at first sight, but in depth far less, on account of the many other motions that it brings with it, as I said already in number 5, in Reply 2. But in reality the

motion of the Sun is much simpler, whether it overtakes the superior Planets or recedes from them, or carries the Epicycles of Venus and Mercury along with it by one and the same motion (for in this the hypothesis of Ptolemy is to be corrected). [Margin: Why the Luminaries are not Retrograde.] The cause, however, why the Luminaries are not retrograde has been sufficiently assigned by us in Book 7, Section 5, chapter 3, Theorems 3 and 4.

[Margin: 4th Reply, very noteworthy.] I reply, 4.: by turning the argument back. For from the annual motion of the Earth mixed with the diurnal it follows that all the points of the Terrestrial globe that lie outside its centre, and all bodies — terrestrial, watery, or semi-aerial — that follow the motion of the earth, whether fixed to the earth or detached from it or hanging, really become stationary twice every day as regards the diurnal motion, direct once and retrograde once, and yet that this is not perceived; and that the Moon, every month, as regards its monthly motion mixed with the annual motion of the earth's centre, becomes Stationary at the quadratures, Direct between the 1st and 2nd quadratures, Retrograde between the 2nd and the 1st of the following Lunation, Swiftest at the Full Moons and Slowest at the New Moons — as regards this motion, that is — and yet that not even this appears to us. So I said already in chapter 6, at the end of number 18, and shall say in chapter 19, number 12; and Galileo himself admits it, as will be said in chapter 14, number 4. Now if it is absurd to posit a real Retrogradation and Station in the celestial bodies, then, since the Earth with its kindred bodies is placed in the number of the Planets and is said to move in its own heaven with respect to the centre of the Universe, it is surely a greater absurdity to posit, in innumerable bodies diverse in number and species, a retrogradatio- n and Station — and one, indeed, so frequent that it is daily, and yet one that can be perceived by no observations, nor proved a posteriori — and to assert the same in the Moon every month, than to posit in a few other Planets a rarer Retrogradation and Station, and one, moreover, founded on observation. Or, if the former is not absurd, neither ought the latter to be absurd. There is no reason, therefore, why the Copernicans should press this argument so often.

III. Argumentum à Cauſa quæ aliarum quarundam rerum Aſtronomicarum redditur à priori per ſolum Annuum Telluris motum.

III. The Argument from the Cause of certain other Astronomical matters, which is given a priori through the annual motion of the Earth alone.

X. With this single motion of the earth substituted, says Kepler in chapter 1 of the *Mysterium Cosmographicum*, the causes of very many things are given which Ptolemy could not give from so many motions of the heaven. [Margin: Why do Venus and Mercury have the same motion as the Sun?] *For, first, Ptolemy could have been asked how it comes about that the three Eccentrics of the Sun, Venus and Mercury have equal revolutions? For the answer is that they are not truly*

revolved themselves, but the one Earth in their place. Moreover, as the same author notes in Book 4 of the *Epitome of Astronomy*, page 535, what Martianus Capella, Campanus [Campanus of Novara] and others — namely Vitruvius, Macrobius and Bede — had an inkling of, Galileo has now demonstrated in his *Sidereus Nuncius* from observations made with the Telescope on Venus, and Simon Marius [Simon Mayr] on Mercury, and we on both: that Venus and Mercury, when they proceed direct and come nearer to their morning Conjunction with the Sun, appear small and round, but when they become retrograde and are near their evening conjunction, appear very large and falcate, or horned. We gave diagrams of these phases, and the arguments, in Book 7, Section 1, chapter 2. From this, moreover, it is evidently gathered that they are illuminated by the Sun in such a way that they go round it. [Margin: Why do Venus and Mercury appear now below, now above the Sun?] Now it seems incongruous that these Planets should be carried now above, now below the Sun; and this incongruity is removed if an annual motion of the Earth is posited, for then their ascent and descent is merely apparent, according as the Earth becomes more remote from them or nearer to them as they go around the Sun.

XI. Likewise it seems unbefitting to the constancy of the celestial motions that the three superior Planets should sometimes scarcely equal little stars of the second magnitude — and this when they come to conjunction with the Sun — and sometimes equal or surpass stars of the first magnitude, and this when they come to opposition to the Sun. The cause of this diversity cannot be given by the ancient hypotheses, but it is given at once by the single annual motion of the Earth: for when the Earth interposes itself between them and the Sun, it approaches them, and therefore sees them much larger than when it recedes from them, so that the Sun is interposed between it and the Planets. [Margin: Copernicus's view on why Saturn, Jupiter and Mars are larger at opposition to the Sun.] *For from this it is possible to notice*, says *Copernicus* in Book 5, chapter 10, *that Saturn, Jupiter and Mars, when acronychal, are nearer to the earth than around their occultation and appearance. But Mars especially, when it shines all night, seems to equal Jupiter in magnitude, distinguished only by its ruddy colour; whereas there it is found scarcely among the stars of the second magnitude, etc. All of which proceed from the same cause, which lies in the motion of the earth.* [Margin: And Gemma Phrysius's.] Gemma Phrysius pursues this very point in a certain Letter to Ioannes Stadius [Johannes Stadius], dated at Louvain on 1555 February 28 [pridie Calendas Martias], asserting that the hypotheses of Ptolemy do not have such evident causes τῶν Φαινομένων [Greek: τῶν Φαινομένων (tōn phainomenōn, "of the phenomena")] as the Copernican ones have. *For that the three superior Planets*, so he goes on, *when* ἀχρόνυχοι [Greek: ἀχρόνυχοι (achronychoi, "acronychal", rising at nightfall)], *that is, placed diametrically opposite the Sun, are always at the perigee of their Epicycle, Ptolemy assumes, and this is* τὸ ὅτι [Greek: τὸ ὅτι (to hoti, "the that" — the bare fact)]. *But the hypotheses of Copernicus necessarily infer it, and demonstrate it* δί ὅτι [Greek: δί ὅτι (di hoti, "through what" — the reasoned why)]. Thus Ptolemy teaches the mere *That*

[Quod], but Copernicus the very *Why* [Propter quid]. Finally, *Kepler* strikes this very chord in his *Mysterium Cosmographicum*, chapter 1, when he says: *Likewise the ancients wondered, not without reason, why the three superior ones are always lowest in their Epicycle at opposition with the Sun, and highest at conjunction, etc. In Copernicus the cause is easily given. For it is not Mars in an Epicycle but the Earth in its orb that causes this variation.* Let the form of this argument, then, be as follows.

XII. [Margin: The argument in form.] *That hypothesis is to be put before the others which, either alone or more evidently, gives the reason a priori why Venus and Mercury have the same motion as the Sun, and seem now round above the Sun, now falcate below the Sun; and why Saturn, Jupiter and Mars always appear nearest the Earth at opposition with the Sun, and therefore largest, but at conjunction with the Sun most remote and smallest. But such is the hypothesis in which the Earth is carried around the Sun by an annual motion. Therefore, etc.* The MAJOR is clear of itself. The MINOR, too, remains sufficiently proved from what was said in numbers 10 and 11.

[Margin: 1st Reply.] I reply, 1.: with precisely the distinction I used in the first reply to the first argument of this chapter; reread it from number 5, and take it as though it were transcribed here.

[Margin: 2nd Reply.] I reply, 2.: granting the Major, by denying the Minor. For both in the Ptolemaic hypothesis — but as reformed by us — and in the Tychonic, the reason of the Phenomena already mentioned is given no less evidently. For it is certain, in the Copernican hypothesis as much as in our own and in the Tychonic, that Venus and Mercury go around the Sun and follow it as the centre of their motions; and from this, as from a true a priori cause, it follows that to the Earth — whether at rest, with the Sun moved annually around the Earth, or carried round the Sun at rest — they appear now round and slender, now large but falcate; and why they are moved by one and the same eccentric motion. Nor is the Earth, with an annual motion, any more the cause of this phenomenon than the Sun with an annual motion; indeed, if all else were equal, the motion of the Sun has the advantage in this, that it is more evident to our sense, so that, as long as we are not convinced of the opposite, we ought rather to assert it. Likewise it is false, what is imputed to Ptolemy, namely that he assumes that the three Superior Planets in the acronychal position, or at opposition with the Sun, are always perigean, or nearest the earth, and at conjunction apogean, or most remote, and gives no cause of this antithesis: for he refers the cause to their motion on the Epicycle in the order of the signs, tempered to the annual motion of the Sun. Tycho, however, refers the cause to Eccentric orbs, but ones carried round by the Sun; and this I wish to be confirmed by no other words and admission than those of Kepler himself. [Margin: Kepler's admission in favour of the Tychonic hypothesis.] For he has this in the *Epitome of Copernican Astronomy*, Book 4, page 537: *Now as regards the three superior ones, Aristarchus, Copernicus and Tycho Brahe demonstrate that, if we also place them around the Sun, and the Sun as the common centre, as*

it were, of the five Planets, so that the motion of the Sun, whether true or apparent, affects the whole orbs of the five Planets, then we are freed — as before, in Venus and Mercury, from two superfluous Eccentrics — so now, in the three superior ones, from Epicycles. As for what he adds — that the agreement which the planets already mentioned have with the motion of the Sun is blind and incredible — this is said gratuitously; and that agreement is much more credible than the annual motion of the Earth, or that magnetic attraction by which he would have them led round by the Sun itself. And if Ptolemy carried Venus and Mercury round perpetually beneath the Sun, this has now, after the use of the Telescope, been removed from his hypothesis.

IV. Argumentum à Latitudine & Inclinatione Planetarum minorum ad Eclipticam.

IV. The Argument from the Latitude and Inclination of the lesser Planets to the Ecliptic.

XIII. I once pointed to this argument in Book 7, Section 4, chapter 5, scholium 3. But Rheticus develops it at far greater length in his *Narratio prima*, on roughly the third page before the end, where, giving the reason why the annual orb of the Earth was called GREAT by Copernicus, he says: [Margin: Rheticus's encomium on behalf of the Great Orb.] *It is called the Great Orb because it has a notable magnitude in relation both to the orbs of the superior Planets and to those of the inferior, such as to be the occasion of the principal appearances*; then he adds: *Further, it is in the latitudes of the Planets above all that one may see how rightly the name Great is given to the circle carrying the centre, etc. The motions of the Planets in longitude do indeed bear remarkable testimony that the centre of the Earth describes the Orb we call Great; but in the latitudes of the Planets its uses, as if set in some conspicuous place, are more evident, since, though it never departs from the plane of the Ecliptic, it nevertheless stands as the principal cause of all the diversity of the appearances in latitude.* He then pursues the doctrine of the latitudes, and over the whole of the last two pages shows how, through the approach of the Earth to the Planets, the angles of inclination are optically increased — angles which the Ancients thou- ght to be increased on account of the Planet's position at the perigee of its Epicycle; and many other things connected with these, which there is no need to transcribe here.

XIV. [Margin: Kepler's view in favour of the latitude of the Planets in the hypothesis of the moving Earth.] Kepler urges this same point in a briefer discourse, but more than once. For in chapter 1 of the *Mysterium Cosmographicum* he said: *Likewise, because of this same approach of the earth to the planets, and its recession, in its orb, the five latitudes of the Planets themselves seem to us to receive some variation; and to save this libration Ptolemy had to establish five other motions, all of which fall once the single motion of the earth is posited.* Again, in the *Epitome of Copernican Astronomy*, Book 4, page 537, he affirmed that through the annual motion of the earth a great many complications in the motion of latitude are

removed from the Theoretical doctrine; and on page 543 he did not hesitate to say: *If the Epicycles go round while the earth stands still, whether according to Ptolemy or according to Brahe, those Epicycles, especially those of the inferior planets, will have to shake their sides in various ways as much as their head and feet — that is, to librate in a double manner; but if the Earth goes, all the orbs are inclined to the Ecliptic most constantly.* In Book 6 of the same *Epitome*, moreover, page 771, he inquires how it comes about that Ptolemy made the Epicycles of the Planets librating with a double reciprocation, when nevertheless, from the more recent observations he had adduced for Mars in chapter 14, their inclination has been found to be fixed and constant. And he answers that this happened through ignorance of the annual motion of the earth. For Ptolemy was looking at the limits of the Planetary orbit, stretched out towards certain parts of the fixed stars; and although in reality these limits decline constantly from the plane of the Ecliptic, nevertheless, as the Earth goes round, the Planetary orbit seems to stretch out towards the Earth now its northern limit, now its southern, now its nodes. But Ptolemy transferred the circuit of the Earth to the centre of the Epicycles of Venus and Mercury running through the Zodiac annually; and in this Epicycle he called perigee that point which at any given time is stretched out towards the earth, as if it were a single point, when in reality all the parts of this Epicycle (which Copernicus calls the Eccentric) become perigees in order, successively, by accident. So it came about that what Ptolemy named the perigee seemed, by a kind of libration, now to be in the North, now in the Ecliptic itself, now in the South. Having set out this doctrine, he adds this Epiphonema: *And behold a most evident argument for the annual motion of the Earth around the Sun. For since the Eccentrics of the Superior planets have fixed inclinations to the Ecliptic, why should the Eccentrics of the Inferior ones alone be laid down as librating, and with a double libration, when every libration of orbits is absurd in itself, because it produces a tortuous path of the planet instead of a circular one? As much probability, then, as the fixed inclination has, so much does the motion of the earth gain from it; and as much absurdity as the double libration has, so much does the immobility of the earth totter.* Gathering the argument into its formula, then, it runs thus.

XV. [Margin: Form of the 4th argument.] *That hypothesis is to be preferred to the others through which the latitudes of the five lesser Planets keep a constant angle of inclination to the Ecliptic, without libration of the orbits and without tortuousness of the planetary path. But the hypothesis of the Earth carried annually through the great orb is the only one of this kind. Therefore.* The MAJOR, at least other things being equal, is evident: for motions are not to be multiplied in vain, much less librations and windings of motions, if the celestial phenomena can be saved otherwise and without those complications. The proof of the MINOR has been sufficiently suggested by what was said in numbers 13 and 14: for it is by the approach and recession of the Earth to and from the Planets alone that the variation occurs in the angle by which the orbits of the Planets are inclined to the Plane of the Ecliptic; nor is it apparent how, without this motion of

the earth, that variation could come about and be explained without other complications.

[Margin: 1st Reply.] I reply, 1.: to the Major, with exactly the distinction I brought forward in the first reply to the first argument of this chapter, from number 5; since it is of great moment, I am neither ashamed nor weary to use and repeat it so often.

[Margin: 2nd Reply.] I reply, 2.: granting the Major[41], by denying the Minor. For both through a single spiral motion, made by an Intelligence towards the sides of the world with looser and tighter spirals, and in the Tychonic or Danish hypothesis, that constancy of Inclination can be saved by means of the parallelism of the planes, as is clear from the Theory of latitudes of Longomontanus, which we set out in Book 7, Section 4, chapter 4. That Ptolemy erred in the measure of the inclinations and of the latitudes, lacking suitable observations, does nothing against the hypothesis of the Earth at rest considered in itself. For the Earth, carried annually through the plane of the Ecliptic, by the very fact that its centre is always in the plane of the Ecliptic, cannot vary the latitudes of the Planets except by optically increasing the angle of inclination by its approach and diminishing it by its recession; the rest, which concerns the latitudes, the regions of the latitudes and the motion of the Nodes, as deduced from observations, must be saved through some theory other than the annual motion of the Earth in the Ecliptic. Now if the Planets, too, so temper their motion of latitude to the annual motion of the Sun that they obtain through this motion a latitude equal to, and of the same character as, the one they obtain through the motion of the Earth, and in such a way that the inclination of the planetary orbit to the Ecliptic, derived geometrically from such a latitude, is perpetually of the same measure — that is, that the plane of the Epicycle is always parallel to the plane of the Ecliptic — it will not be necessary for this to be accomplished through the annual motion of the Earth. For Copernicus already admits that all the Phenomena can stand saved both ways, as to the substance of the truth, in either hypothesis. And so that you may see that it is not from the hypothesis of the Earth at rest, in itself, that errors, or inconstancy of the latitudes and inclinations, arise, nor from the hypothesis of the moving earth that constancy and truth arise, I am pleased to show from Kepler himself what not only Ptolemy but also Copernicus did wrong in this, through what he himself sets out in the *Commentaries on Mars*, chapter 14, whose title is: *The planes of the Eccentrics are* ΑΤΑΛΑΝΤΑ [Greek: ΑΤΑΛΑΝΤΑ (atalanta, "not swaying", that is, not librating)], that is, non-librating. He begins, then, thus: *The perplexity of his hypothesis deceived Ptolemy, so that he heaped many monsters into the doctrine of latitudes. For when he considered that the plane of the Epicycle is twisted in all directions, and did not see at once, through those fogs of his hypothesis, that the plane of the Epicycle is parallel to the plane of the Ecliptic, he contrived a triple latitude; and so that contraries might be propped up by contraries, he wholly dislocated*

[41]printed *Maiote*, for *Maiore*

his Epicycle from its parallel position. And it was neither from the testimony of the observations, which he did not have so frequently, nor from their measure where he did have them, that he chose middle values (being distrustful of certainty), placing the extremes in error. Hence you may see that in the usual calculation — in Magini's Ephemerides, say — no conjunction at all of Mars and the Sun occurs that is not (as they say) bodily. If that were true, nature would have contrived the tempering of the latitudes in vain — contrived so that the agitations of the sublunary powers should not be excessive, through bodily conjunctions occurring frequently. So much concerning Ptolemy, and indeed concerning Magini too, who, although he uses Copernican numbers, nevertheless adheres to the Ptolemaic hypothesis. Then, concerning Copernicus, he goes on thus: *Copernicus, himself ignorant of his own riches, took upon himself the task of expressing Ptolemy entirely, not the nature of things — to which, nevertheless, he had come nearest of all. On which matter read Rheticus in his Narratio. For, delighted that through his approaches of the earth to the stars the appearances of the latitudes are increased, he nevertheless did not dare to reject the residual Ptolemaic increases of the latitudes (which this approach of the earth would not achieve); but, so as to express them too, he contrived librations of the planes of the Eccentrics, by which the angle of inclination (constant and fixed for Ptolemy) should be varied; and this (which is like a monster) not according to the laws of the motions of its own Eccentric, but of the earth's orb, which is entirely foreign to it: see Copernicus, Book 6, chapter 1.* See, then: from the bare hypothesis of the moving Earth, librations of these planes are not avoided unless the quantity of the latitudes is first corrected from more certain observations. Now let us see whether, in the Tychonic hypothesis too, and in the Ptolemaic though corrected, that constancy of the inclinations can remain saved. Kepler therefore continues in the same chapter; and when he had said that he had demonstrated, from the Tychonic observations made of Mars and in the preceding chapters — and would prove below, in part 5 of the Commentaries, with several arguments — that the declination of the orbit of Mars from the Ecliptic is everywhere constant, and that there is no libration of the inclinations of the Eccentric of Mars, he concludes universally, from the observations of nearly Mars alone, thus: *Let us therefore conclude this most firmly: that the inclination of the planes of the Eccentrics to the Ecliptic (for why should I not conclude it in general, when there is no cause why it should belong to one planet alone? although I have the same demonstrated from observations in Venus and in Mercury too) does not vary at all. And let him who follows Ptolemy learn from this that the plane of the Epicycle is perpetually parallel to the plane of the Ecliptic.* It suffices, therefore, for removing the complications of the librations and preserving the constancy of the inclinations, if the planes of the Ptolemaic Epicycles, or of the orbs substituted for them, are always parallel to the plane of the Ecliptic, whether this comes about with the Earth moving or with it at rest; nor is the perigee of the Planet, in which the greater latitude appears, produced more by the approach of the Earth to the Planet than by that of the Planet to the Earth.

V. Argumentum ab Aequante ſublato per Annuum Terræ motum.

V. Argument from the Equant, removed by the annual motion of the Earth.

XVI. [Margin: Rheticus's view against the Ptolemaic Equant.] This argument is very slight, as its solution will show; and yet Rheticus too invoked it in his *Narratio prima*, where, speaking of the annual motion of the Earth introduced by Copernicus, he says: *By this one means the Lord Teacher saw that it could conveniently come about that — what is most proper to circular motion — all the revolutions of the circles in the world should be moved uniformly and regularly about their own centres and not about alien ones.* [Margin: And Copernicus's.] Indeed Copernicus himself, discussing the hypotheses of the Ancients in Book 5, chapter 2, said: *They concede, therefore, that here too the uniformity of circular motion can come about about an alien centre and not its own, etc. These and similar things gave us the occasion to think about the mobility of the earth and about other ways by which uniformity and the principles of the art might remain, and the account of the apparent inequality be rendered more constant.* [Margin: And Galileo's.] Finally, Galileo, in Dialogue 3 on the system of the world, page 252 of the Latin version, brings in Salviati speaking thus: *Will not all the sects of Philosophers say that this is a great inconvenience — that some body movable in a circle should be moved irregularly about its own centre and regularly about some other point? Yet such deformed motions exist in the Ptolemaic fabric of the world; but in Copernicus all the motions are uniform about their own centre.* Let the argument now be formed in this way.

XVII. [Margin: 5th argument in form.] *That hypothesis is to be preferred to the others through which alone the absurdity of the Equant circle is removed — that is, of the circle in which neither the Planet nor the centre of the circle carrying the Planet moves, and yet about whose centre the Planet is supposed to be moved uniformly. But the only hypothesis of this kind is that of the Earth moved annually. Therefore, etc.* The MAJOR is evident from the uniformity owed to the celestial motions in their own circles, not in alien ones; otherwise, if they are moved uniformly in alien circles, they must be moved non-uniformly about their own centre, and so have not only an Optical but also a Physical, or real, inequality, which is absurd. The MINOR is established at least by the authority of Copernicus, Rheticus and Galileo, adduced a little earlier.

[Margin: 1st Reply.] I reply, 1.: if the Equant circle — that is, some real inequality in the motion of the Planets — is absurd, I concede the Major; if it is not absurd, I deny the Major. But I have taught, in Section 2, chapter 4 of this Book, that it is not absurd, but very fitting for them in relation to their end.

[Margin: 2nd Reply.] I reply, 2.: granting the Major, I deny the Minor. For the inconvenience of the Equant circle, or of the bisected Eccentricity, if there is any, is removed also in the hypothesis of the Earth at rest, as in the Tychonic, the Danish and our own; and conversely it is not removed by the annual motion of the Earth in itself. This is manifest from the fact that Kepler and Boulliau,

who defend the annual motion of the Earth as strongly as anyone, nevertheless retained, by bisecting the Eccentricity of the Planets, the equivalence of the Ptolemaic Equant; and, by moving the Planets in an Ellipse about the two foci, or umbilici, of the Ellipse, they conceded that one inequality is Optical with respect to one focus and the other Physical with respect to the other — as is clearly established from what was said in Book 3, chapters 22 and 23, and in Book 7, Section 2, chapter 5, numbers 12 and 13, where, and also in Book 7, Section 2, chapter 1, scholium 2, I have set out many things for the explanation and use of the Equant. Therefore the imperfection of the Equant, if there is any, is not of itself connected with the hypothesis of the Earth at rest, nor of itself torn away by the hypothesis of the Earth going round.

CAPVT X. Proponuntur, & Diſſoluuntur Quinque Argumenta pro Annuo Terræ motu, deſumpta ex quarũdam aliarum rerum cæleſtium Motibus, aut Variationibus.

CHAPTER X. Five Arguments for the Annual Motion of the Earth, taken from the Motions or Variations of certain other celestial things, are set out and refuted.

I. Argumentum à Fixarum diametro, motu, & diſtantia apparenti variatis.

I. Argument from the diameter, motion and apparent distance of the Fixed stars, as varied.

I. I remember having read in someone — or at any rate having received in letters sent to me from Germany — that a certain man had dared to assert that the same Fixed stars were seen by him larger in the northern quarter when the Earth saw the Sun under the beginning of Capricorn than when it saw it under the beginning of Cancer. From this he gathered that the effect came about through the Earth's approach to the northern quarter, by force of which Arcturus would then appear larger than itself when the Earth had receded to the southern Quarter. Io. Pena and Io. Stadius too, as I reported in chapter 3, scholium 2, thought that by the Earth's approach the motion of the Fixed stars is seen faster, and by its recession slower; we refuted them there. Finally, Rothmann, in Tycho, tome 1, page 684, said that the distances of the Fixed stars from one another are increased by 2′ through the approach of the Earth and diminished through its recession, and that he had observed this. But either this is a wholly voluntary Fiction — since nothing of the kind has appeared to us, who have been observing the stars for many years now — or that phenomenon arose from the differing thickness of the vapours on summer and winter nights. Otherwise, it is clear enough from Copernicus himself, *De Revolutionibus* Book 1, chapters 5, 6 and 10, that the whole annual orb, through which the Earth is supposed to move, has no sensible ratio to the sphere of the eighth Orb, or of the Fixed stars, but is like a point; and so, whether Arcturus or any other

Fixed star is viewed from the Earth placed under Cancer or from the same placed under Capricorn, no variation can appear of itself either in its apparent magnitude or in its meridian altitude. [Margin: The variation of the Fixed stars in magnitude is a fiction.] And yet if one did appear, it ought to appear greatest in the stars placed on the Ecliptic, smaller in those distant from the Ecliptic, and none in those near the poles of the Ecliptic, as Galileo demonstrates in Dialogue 3 on the System of the World, from page 281 of the Latin.

II. Argumentum à Satellitibus Iouis.

II. Argument from the Satellites of Jupiter.

II. [Margin: How the revolutions of the Jovian Satellites are regular.] Go to Kepler, in the *Epitome of Copernican Astronomy*, Book 4, part 2, page 537, and you will read in it this argument: *Marius,* he says, *in his Jovian world, discovered that the restitutions of the Jovian satellites about Jupiter, which we project from the centre of the earth onto Jupiter, are by no means regular, but that they are regular if they are referred to lines drawn from the centre of the Sun through Jupiter. This, of course, stands in the place of a very great argument that the orbit of Jupiter is ordered about the Sun, and that the distance of the Sun from the centre of Jupiter's orbit is certain and in a certain way fixed, whereas the Earth varies its distances from this centre through the year.* But it can be answered that this has not been demonstrated by Simon Marius, but deduced only from conjectures that are not very strong; and that, this granted, it does not follow from it, necessarily or even very probably, that the Earth is moved with an annual motion rather than the Sun, but at most that the Sun is the centre of the Jovian system; or that, just as the Sun is the first exemplar of one carrying its satellites Mercury, Venus and Mars round itself, so it is for Jupiter, leading its satellites round.

III. Argumentum à Lunæ Variatione, & Libratione.

III. Argument from the Variation and Libration of the Moon.

III. [Margin: The cause of the lunar Variation.] Tycho observed that, besides the first and second inequality, or anomaly, which the Moon undergoes, it has a third inequality as well, more manifest in the Octants but ceasing in the Syzygies and quadratures, as we set out in Book 4, chapter 18, number 8, and chapter 26, number 9. Tycho and Longomontanus refer its cause to a libration of the lunar Epicycle, as we showed in the same place; Kepler, by contrast, to the illumination of the Sun and its species reflected from the earth onto the Moon, as we set out in the same Book 4, chapter 27, from number 5, and in scholium 6. But Ismaël Boulliau, in Book 3 of the *Astronomia Philolaica*, chapter 11, thinks that the truer cause of this Variation is the Reflection of the line of the lunar apogee, arising from the annual motion of the Earth, by which the whole lunar system is carried along. For when the apogee is advanced by the reflection from the Syzygies towards the dichotomies, the Moon thereby acquires a new acceleration; and when it is drawn back from the quadratures

towards the Syzygies, the Moon undergoes a certain slowness in the Zodiac. This he thinks is the genuine, proximate and simple cause of this Variation, whose measure he investigates afterwards in chapter 12. See more on these matters, if you please, in our Book 4, chapter 27, numbers 13 and 14.

IV. [Margin: The cause of the lunar Libration.] Besides this Variation, a certain Libration has been observed in the Moon, by force of which the lunar spots appear now nearer to the eastern and western limb, now farther from them; so that when the Caspian Spot is most remote from the western edge of the Moon, then the Spot called by Langrenus [Michael Florent van Langren] and by us the Lake of Posidonius — which Galileo, however, calls the Corican and Hevelius the Mareotic — is nearest to the eastern limb of the Moon, etc. More on this libration below, in the Appendix to Book 4, on the Moon. Galileo, in the dialogues, said that this libration was instituted so that the Moon might keep a certain direction towards the axis of the moving earth; but Boulliau, in Book 3 of the *Astronomia Philolaica*, chapter 13, rejects this and concludes that the axis of the Moon about which that libration is performed is either perpendicular to the plane of the Ecliptic or insensibly inclined to it — by as great an angle, perhaps, as that by which the planes of the Ecliptic and of the lunar orbit are inclined to each other, namely about 5⅓°: see the diagram of this matter in our Book 4, chapter 9, number 4. With these premised, let the Argument be:

V. [Margin: The argument in the form of an Enthymeme, and a twofold Reply.] *The Variation of the lunar motion and the Libration of the lunar body are better explained on the supposition of the Earth's annual motion than on the supposition of its rest. Therefore the annual motion of the Earth is to be supposed rather than its rest.* It is answered, 1., by denying the antecedent: for they are explained equally well by a libration of the lunar Epicycle, or of the lunar body itself, according to what is to be said in the Appendix to Book 4. I reply, 2.: granting the antecedent, by denying the Consequence, because other things are not equal. Indeed there are other, greater absurdities in the annual motion of the Earth, and the exclusion of these outweighs this very slight convenience, by which a partial cause of the lunar Variation and Libration could be brought forward through the annual motion of the Earth; and that lunar Libration is completed wholly within a month, and has no analogy with the annual motion of the earth. Besides, what Boulliau and Hevelius have so far published about that libration agrees neither with themselves nor with our observations, so that this matter must be deliberated on more maturely, and a more uncertain cause must not be sought from uncertain phenomena.

IV. Argumentum à Nouis Stellis.

IV. Argument from the New Stars.

VI. Thomas Diggesseus [Thomas Digges], an Englishman of Kent, on the occasion of the new star which was seen in Cassiopeia in 1572, thought — to

use his own words as reported in Tycho, tome 1, page 658 — *that an opportunity had been offered of testing whether the motion of the Earth supposed in Copernicus's theories will be the sole cause why this star diminishes in apparent magnitude. For if it is so, at the vernal Equinox, always decreasing, it would be seen at its least magnitude. But afterwards, if it lasts, growing little by little, in the following July it will be of almost the same brightness as in its first appearance. But at the autumnal Equinox it will be seen of unusual magnitude and also of unusual splendour. No other cause could be assigned to a variation of such apparent quantities than its elongations from the Earth.* So Digges, but with a wholly empty hope. [Margin: Thomas Digges's empty conjecture about the motion of the Earth from the magnitude of the new star.] For that star, in 1572, about the beginning of November, was seen to exceed Lyra, Sirius, and Jupiter itself when acronychal; in January of 1573 it was a little less than Jupiter but a little greater than Lyra; in February and March it was seen equal to Lyra; in April and May it resembled stars of the second magnitude, and in June, July and August stars of the third rank; but in September, October and November, more attenuated, it scarcely equalled stars of the fourth class; in December of 1573 and January of 1574 it was equal to stars of the fifth brightness, and in February to those of the sixth; and at last, in March, it became invisible, as Tycho narrates in tome 1, page 301. Therefore it did not change its magnitude in the way that the approach and recession of the Earth would require: for it ought to have been seen equal to Jupiter again in November of 1573. Moreover, as Tycho notes against Thomas on page 660, it ought to have appeared greatest when the Sun was about the beginning of Scorpio and the Earth about the beginning of Taurus, and least when the Sun was placed about the beginning of Taurus and the Earth about the beginning of Scorpio, if that variation had come from the annual motion of the Earth; for the longitude of the star was about the 7th degree of Taurus. "But let us grant," says Tycho in the same place, from page 658, "that the star grew and decreased according to its approach to the earth, and that it was, as Digges would have it, about the region of Mars, with a parallax of 2′; it would certainly have undergone the parallax of the annual orb, and at the autumnal Equinox it would not have been seen under the same place of the Fixed stars, and equally distant from the Fixed stars of Cassiopeia, as that under which it was seen at the vernal Equinox. And yet Digges admits, in his treatise on this star, that it stood motionless for the whole time of its appearance and was seen under the same place of the Fixed stars." But if he had located it in the eighth sphere, its distance from the Earth according to Copernicus is so great that the diameter of the annual orb is insensible in relation to it, and no variation in the apparent magnitude of the star could have been detected from the mere approach and recession of the Earth. Since, therefore, that star decreased continuously, Digges must acknowledge that it either withdrew into the depth of the aether or perished little by little.

V. Argumentum à Traiectione Cometarum.

V. Argument from the Trajectory of Comets.

VII. [Margin: Kepler's argument for the annual motion of the Earth from the motion of Comets.] Here indeed Kepler triumphs, in his history of the three Comets which appeared in 1618. For there, in Epichireme 8, which is found on page 91, he argues thus: *With the trajectory of the Comet supposed rectilinear, and slackening little by little from a uniform motion by ordered decrements, the Comet of 1618 offers a twofold testimony to the motion of the Earth: one by its motion in longitude, the other by its motion in latitude.* As to longitude, he strives to prove this from the fact that the orbit of the Comet, divided into daily motions, appeared divided disorderly: *But no straight line,* he says, *divided into parts by ordered decrements can appear divided disorderly while the Earth is at rest; it can, however, if the Earth goes round the Sun and makes progressions that are sensible in comparison with the Comet's speed.* See his Theorem 30 of the same little work. As to latitude, the same author busies himself to suggest that, from the observed latitudes of the Comet, the Comet deflected in two places from the direct path of a great circle towards the Ecliptic — first in Libra and Virgo, and again in Cancer — as the Earth deflected towards the Sun, and that it declined little from a straight line parallel to the straight line of the trajectory along which he supposes the Comet to have proceeded. For by this supposition he concludes, on page 92: *Therefore the apparent path of the Comet, if the true trajectory keeps its own proper order of decrements, necessarily becomes tortuous; and conversely, because the path of the Comet was tortuous, then, given a rectilinear and ordered trajectory, it follows that the Earth moves, etc.* And on page 93 he says that he was led to assert the rectilinear motion of Comets not by a desire for novelty, but because he found in rectilinear motion evident causes of many appearances which it is not easy even to dream of in a circular motion of the Comet. And on page 97, asking why the Comets of 1607 and 1618, and many others, having become slow, began to curve their paths, he answers that it was a mere deception of sight, as are also the stations and regressions of the Planets, and that this arises from the recession of the Earth: for a Comet much elongated from the Earth along a straight line much also diminishes the appearance of its latitude and its progressions in longitude. Finally, on page 98, he ends the first little book with this clause: *In short, as many Comets as there are in the heavens, so many arguments are there (besides those drawn from the motions of the Planets) that the Earth is moved with an annual motion about the Sun. Farewell, Ptolemy; I return to Aristarchus, with Copernicus as my guide.* Which appearances of Comets they are that seem to be better explained by a rectilinear motion of the Comets mixed with the annual motion of the Earth, I have already taught sufficiently from Kepler in Book 8, Section 1, chapter 26, where I treat this argument somewhat more fully. [Margin: Solution of the argument.] There, from number 5, I refuted this argument — which is not, of itself, without some probability — by four objections brought against Kepler; let the Reader have recourse to them,

so that we are not forced to repeat the same things here. Let him remember, besides, that the absurdities in the annual motion of the Earth, already reviewed in chapter 9 of this section after number 5, outweigh this spark of probability struck violently out of the Comets in favour of the annual motion, as if out of flint — especially since Kepler's argument does not proceed absolutely, but from a feigned hypothesis, both of the rectilinear motion of the Comets and of its decreasing in order, and he has demonstrated neither hypothesis. Tycho, moreover, would answer with the words found in the letter to Magini written in 1590 on the Kalends of December [1590 December 1], which is on page 81 of Magini's own *Directions of the primum mobile*, where he says this: *Indeed even the Comets themselves of which I spoke, insofar as some of them proceeded about the region opposite the Sun, denied the annual motion of the earth asserted by Copernicus: for it took nothing away from their destined course, much less forced them, as we watched, to be driven backwards or held back with a slower gait.*

CAPVT XI. Proponuntur & Diſſoluuntur Duo Argumenta pro Motu Terræ Annuo, vnum ex Mutatione Lineæ Meridianæ; alterum ex Mutatione Altitudinis Poli, de quibus multa ſcitu digna referuntur.

CHAPTER XI. Two Arguments for the Annual Motion of the Earth are set out and refuted: one from the Change of the Meridian Line, the other from the Change of the Altitude of the Pole; on which many things worth knowing are reported.

I. So far we have treated those Arguments which, relying on true phenomena, seemed to win some probability for the annual motion of the Earth — except, however, arguments 1 and 5 of the preceding chapter, which, lacking the truth of the phenomenon they assumed, collapsed at once. In this chapter, by contrast, we must fight with mere shadows and dreams, and so the victory will be easier, once the very falsity of the assumptions is detected. On this occasion, however, two very celebrated questions will be dealt with, pertaining partly to the doctrine of the primum mobile and partly to Cosmography: namely, whether the Meridian Line and the Altitude of the Pole change from time to time.

I. Argumentum à Mutatione Lineæ Meridianæ.

I. Argument from the Change of the Meridian Line.

II. Iosephus Scaliger [Joseph Justus Scaliger] judged that the Meridian Line changes, not so much from observation as from the Theory of the equinoctial precessions. For in that *Diatriba* of his on the anticipation of the Equinoxes he seemed to himself to have demonstrated that the poles of the Equinoctial are different from the poles of the World; that the poles of the Equinoctial circle are indeed movable; and that from this comes the motion of the equinoctial points against the order of the signs, on account of which the Fixed stars appear to

move in the order of the signs. His chief argument was that the star they call the Pole star, which is at the tip of the tail of Ursa Minor, was, as it is now, so also formerly, in the time of Eratosthenes and Hipparchus, and indeed of Eudoxus, the most northerly of all the stars of this constellation, and yet it was formerly distant from the Pole of the celestial Equator by 18°, [Margin: Scaliger's fiction about the change of the Meridian line.] in the time of Hipparchus by 12° 24′, while in the year of CHRIST 1600 it would be distant only 3° 24′. From this fiction, among the other corollaries, he likewise deduces this one, which is fifth in his order and is expressed on page 70 in these words: *Meridian Lines drawn on a plane change their position with the progress of time.* "For all Meridian lines," he says there, "pass through the poles of the Equator; but the Poles of the Equator are movable; therefore the Meridian lines too are movable" — namely, against the order of the signs. And at the end of the Corollary he brings this inference: *Therefore, as many equinoctial circles as there are, so many will be their poles; and as often as the poles change, so often will the Meridian lines passing through those poles manifestly change. For the Meridians do not pass through the poles of the World, but through the poles of the Equinoctial.*

III. But just as it is false that the star at the tip of the tail of Ursa Minor was formerly the Pole star and the most northerly of all, so it is false that the poles of the World are different from the poles of the Equator; and consequently what is deduced from this is false, namely that the poles of the Equator, the Meridian circles, and the Meridian lines that indicate them, all change. From what source that false assumption crept into Scaliger's mind, and the confutation of this fiction, we have already sufficiently indicated in Book 3, chapter 28, number 10, and in Book 6, chapter 4, in the Appendix on the pole star, from number 3. Scaliger has, moreover, been abundantly refuted by most learned men of our Society: by Dionysius Petavius [Denis Pétau], in Book 3 of the dissertations of the *Uranologion*, and by Paulus Guldinus [Paul Guldin], in the Refutation of the *Elenchus* of Calvisius, written against the Gregorian Calendar, Book 2, chapters 9 and 10. Further, this change of the Meridian line, of the kind that ought to exist on Scaliger's view — namely, that the northern part of this line should deflect continually towards the West — has not been confirmed by any experiment. Nor, if it were granted, could anything be derived from this change to confirm the motion of the Earth; for a change of this kind does not follow from the motion of the Earth, but from the motion of the poles of the Equator. Otherwise, if it came from the annual motion of the Earth, the whole change of the Meridian lines would have to be completed within any one year, and the same change would have to return whenever the Earth was in the same place of the Ecliptic.

IV. Let us now hear Galileo, at the end of Dialogue 4 on the System of the World, on the second page from the end, narrating thus in the person of Salviati: [Margin: Cesare Marsili, asserter of a change in the Meridian line.] *There arises at this time a certain fifth novelty, from which the mobility of the terrestrial globe may be argued, through what has been very subtly uncovered by the Most Illustrious*

Lord Caesar [Cesare Marsili], sprung from the most noble family of the Marsili of Bologna, and himself enrolled in the College of the Lincean Academicians, who relates in a certain most learned writing that he has observed a certain continual, though very slow, change in the Meridian line. How great that change was, however, and towards what quarter it was noticed, and by what means the observation was made, Salviati does not add there. I, for my part, have not been able to find this writing, although in the papers of the most excellent Lord Carolus Antonius Manzinus [Carlo Antonio Manzini] and of Bartholomaeus Provalius I have read certain observations made in the presence of the already mentioned Lord Cesare Marsili on that marble line which Master Egnatius Dantes [Egnazio Danti] had constructed here in Bologna in the very great Church of San Petronio, as I reported when dealing with the Bologna Gnomon in Book 3, chapter 6, from number 3, where I displayed a diagram of this Gnomon and of the already mentioned marble line. From this line, perhaps, the occasion was taken for suspecting this change. For some Bolognese think that that marble line, or path, laid by Egnatius Dantes in the pavement of San Petronio, was the Meridian line, when in fact it is not, but deflects from the exact Meridian line towards the East in its northern part by 9° 6′ 20″, as I discovered by a most accurate observation together with Fathers Franciscus Maria Grimaldus [Francesco Maria Grimaldi] and Franciscus Zenus. The reason why that marble path could not be laid upon the meridian line itself was the obstacle of the wall and of the front column, which is near the steps of the high altar: for that line would have turned out very short, and would not have shown the people clearly the days of the Solstices and Equinoxes, as Egnatius Dantes wished, at the time when the question of correcting the Roman Calendar was being most actively debated, because the vernal Equinox had regressed from the 21st of March to the 11th. But Egnatius Dantes himself, too, in the description of that Gnomon which is annexed to his *Anemographia*, published in 1578, teaches clearly enough that that marble path is not the Meridian line itself, but declines from the Meridian towards the East in its northern part, since he says that the image, or ray, of the Sun descends a little after noon to that marble line. His own words are these: *Since, however, the Sun does not always reach the points of the equinoxes at noon or near it, the altitude of the Sun must for that reason be determined while it is on the gnomonic line; we shall have it from the proportion of the line AB, that is, of the height of the gnomon, to the line drawn from A, the beginning of the gnomon, and terminated at the ellipse of the Sun; and if to this is added what the Sun has travelled after noon in descending toward the gnomon, and with the altitude of the equator of Bologna, then the Sun will be said, etc.*

V. But wherever this suspicion finally arose for Lord Marsili, so long as no change in the meridian line is demonstrated, we can by no means be persuaded of it — we, I say, who have long since found out by manifold experiment how deceptive the observation of this line is, and who have therefore been forced to resort to new and subtler methods of verifying it. I indicated some of them in Book 1, chapter 10, in the scholia, and will set them out more fully in Book

10, among the Cosmographical Problems. Meanwhile one must guard against refractions, the variation of the solar declinations, and many other things that hinder the exact perfection of this procedure. I am therefore not surprised that some, as Father Iacobus Viua once wrote to me from Germany, found a difference between the meridian line taken from the fixed stars and the one taken from the Sun, and again between one taken from the Sun before noon and one taken after noon. But if it is once exactly obtained, and many years later is investigated again at the same place on the Earth by the same method and with the same care, I have not the least doubt that it will be found exactly the same. I have proof of this from the orientation of the most holy House of the most blessed VIRGIN at Loreto. [Margin: The orientation of the House of Loreto.] For the Angels placed it so that, as then, so now it faces exactly the four cardinal points of the world: one straight line drawn at right angles from one wall to the opposite wall marks the meridian, and another, cutting this at right angles, designates the parallel of the equator. This was so that it might be understood to be a most safe refuge, to which mortals could flee from the four quarters of the world. [Margin: Three arguments: the meridian line is unchangeable.]

Moreover, the unchangeability of the meridian lines follows rather from Copernicus's own hypothesis. For in order to safeguard intact, through the motion of the Earth, all the phenomena that the usual hypothesis explains with the Earth at rest, he laid down that the axis of the terrestrial equator should always move parallel to itself and towards the same parts of the heaven, as we set out in chapter 4, numbers 16, 22, 23 and 25. From this it follows that the meridians are always the same on the terrestrial globe and perpetually face the same parts of the world, as far as sense can tell, and that no sensible difference can ever be discerned between the meridian lines of one and the same place, provided they have been laid out with equal care. A change of the meridian line would therefore rather stand in the way of the Copernican position. Galileo did not consider this; out of an excessive itch to prop up the Earth's annual motion from any quarter whatever, as soon as he heard that Marsili asserted a change in the meridian line, he conceived the hope of hammering out from this too some clever argument for the Earth's annual motion. [Margin: Galileo's itch to argue for the annual motion of the Earth.] Lastly, the magnetism of the Earth itself, which Galileo did not reject, requires that its axis keep its position most constantly, turned immovably and perpetually towards the same points of the heaven, as William Gilbert clearly teaches in *De magnete* book 6, chapter 2, Cabeo in book 3, chapter 4, and Zucchius [Niccolò Zucchi] in the *Nova de machinis philosophia*, part 5, section 10. We therefore do not yet believe what Athanasius Kircher, in book 2 of the *Magnes*, p. 489, promises to demonstrate: that, from static principles, the terrestrial globe has changed its position in every age. [Margin: The immobility of the terrestrial globe.] For he has not yet demonstrated it; nor are the changes of heavy bodies that occur on the surface of the Earth sufficient to cause a motion of trepidation, since, in respect of the

whole terrestrial globe and of the air to be driven round it, they are so light that they would not equal the finest atom added to an enormous balance. And yet this motion of trepidation would do nothing towards a change of the meridian line, or towards establishing the Earth's annual motion.

II. Argumentum à Mutatione Altitudinis Poli.

II. The argument from the change in the altitude of the pole.

VI. Two questions of no small importance present themselves for investigation here: first, whether the altitudes of the pole at the same places on the Earth change by some annual or secular variation; second, whether, if we were certain of such a variation, the Earth's annual motion would follow from it. As to the first, Pliny the Elder seems to have given occasion to both these questions in book 36, chapter 10, with this account: [Margin: Pliny's account of the change of the equinoctial shadow. [?]] *To the obelisk which stands in the Campus Martius the Deified Augustus gave a remarkable use: to catch the shadows of the Sun, and so the lengths of the days and nights. A pavement of stone was laid out to the measure of the obelisk's height, so that the shadow at Rome at the sixth hour of the closing day should be equal to it, and that day by day it should decrease little by little along rulers of bronze set into the stone, and then grow again. A thing worth knowing, and of fertile ingenuity. Manlius the mathematician added a gilded ball to the apex, so that at its top the shadow would be gathered into itself, whereas the apex would throw out lengthenings now one way and now another — a principle, they say, learned from the human head. This observation has not agreed for nearly thirty years now: whether because the Sun's own course has fallen out of tune and the heaven has changed in some way; or because the whole Earth has been shifted somewhat from its centre, as I hear has been detected in other places too; or because the gnomon alone was twisted there by earthquakes; or because the mass has settled through the floods of the Tiber — although its foundations are said to have been laid as deep in the earth as the height of the thing set upon them.* From these words nothing certain or even probable can be gathered for the motion of the whole Earth, only the signs of Pliny's wavering mind. It is more credible that the error arose partly from the day of the true equinox, which was wrongly noted in the calendar and treated as immovable, so that the equinoctial shadow did not appear as long as it was thought it ought to be; and partly from the settling of the stone pavement, the ground having been trodden down for almost a whole century, so that in Pliny's time the marble path no longer made a right angle with the perpendicular line of the obelisk, as it had done in Augustus's time. But Scaliger, in his *Diatriba* on the equinoxes, p. 72, misusing this passage of Pliny and asserting that no variation occurred in the obelisk or through the settling of the stone, attributes the whole discrepancy to a change of the meridian line. Leaving Pliny and Scaliger aside, then, let us come down to more recent authors.

VII. Towards the end of the fourteenth century Dominicus Maria Ferrariensis [Domenico Maria Novara], a man endowed with the highest gifts and the teacher of Nicolaus Copernicus, was the first, so far as I know, to raise this opinion about a change in the altitude of the pole, in a certain treatise or prognostication published at Bologna in the year 1489. From it Maginus, in Canon 8 of the *Secunda mobilia*, and William Gilbert, *De magnete* book 6, chapter 2, selected these words: [Margin: Domenico Maria's opinion on the altered altitudes of the pole.] *In past years,* says Domenico Maria, *while studying Ptolemy's Geography, I found that the elevations of the north pole he gives for the several regions fall short of those of our time by one degree and ten minutes; and this difference can by no means be ascribed to a fault of the table, for it is not credible that the whole series of the book should be equally corrupted in the numbers of the tables. It is therefore necessary to grant that the north pole has moved towards the vertical point. So observation over a long time has now begun to reveal to us what lay hidden from our forebears — not through their idleness, but because they lacked the long-period observations of predecessors. For very few places before Ptolemy had been observed for their elevations of the pole, as he himself testifies at the beginning of his Geography, where he says: Hipparchus alone handed down to us the latitudes of a few places; but very many of the distances, especially those lying towards the rising or setting of the Sun, were conceived from a certain general tradition — not through the idleness of those authors, but because the use of a more careful mathematics did not yet exist. It is no wonder, then, if earlier men did not perceive this very slow motion; for in one thousand and seventy years it shows itself to have moved about one degree towards the zenith of the inhabitants. The strait of Cadiz shows this: there, in Ptolemy's time, the north pole appeared elevated above the horizon by 36 degrees and a quarter, but now by 37 and two fifths. Leucopetra in Calabria likewise shows a similar difference, as do the individual places of Italy — those, that is, which have not changed down to our own times. From this motion, therefore, the places now inhabited will at last become deserted, and others, which are now scorched by the torrid zone, will be brought, though over a long space of time, to our temperate climate; so that this very slow motion is completed in the course of three hundred and ninety-five thousand years.* [Margin: The period of this fictitious change. [?]]

Moreover, Giordano Bruno of Nola, a devotee of a great many novelties, subscribed to this invention of Domenico Maria in his books *De maximo et immenso* and *De infinito ac innumerabilibus*, page 306. [Margin: The opinion of Bruno and Maginus on the changed altitude of the pole. [?]] And, what may surprise you more, so did Io. Antonius Maginus, in his Tables of the *Secunda mobilia*, Canon 8, where he says that he increased the latitudes of places in his catalogue because of the more recent observations of Petrus Pitatus [Pietro Pitati] and others, who found them increased and greater than in Ptolemy's time. And he adds: *Indeed we hold that the latitudes of other places of Ptolemy too ought to be increased, both on this ground and on the authority of Domenico Maria of Ferrara, a man endowed with a divine genius, who was the teacher of Nicolaus Copernicus. It pleases me to share his opinion on this matter with students, especially*

as I know that his writings cannot easily come into everyone's hands: for in a certain old prognostication for the year 1489, printed at Bologna, he puts these words at the head: In past years, etc. — the words we reported above.

VIII. Io. Stadius asserted a plainly contrary account of this change in the History of Astronomy prefixed to his Bergen Tables, following Io. Penna, though with his name suppressed (enough has been said of him in chapter 3 of this section, from scholium 2). [Margin: Io. Stadius's different opinion on this change.] He affirms that the centre of the Earth rises while the motion of the fixed stars is accelerating, and descends while it is slowing, so that it necessarily follows that the Earth moves up and down and is not the centre of the universe. To confirm this invention he calls on Pliny, already cited by us at number 6, and says: *In Pliny's age the whole Earth was detected to have been moved somewhat from its centre; and the same is shown by the latitude of cities and regions, which has been decreasing in various places since Ptolemy's age and plainly reveals itself. And to confirm the matter with an example: Ptolemy, in the Geography, records the latitude of Rome as 41⅔ degrees; and lest you object that some error crept in with Ptolemy — in the city of Rome, on the day of the equinox, the shadow falls short of the gnomon by a ninth part, as Pliny reports and Vitruvius testifies in book 9. Now since, when two sides about the earth of a right-angled triangle are given, each of the angles is given, here too (because 8 and 9 are given) one of the acute angles is given as 48⅓ degrees, which subtends the Sun's altitude above the horizon, and the other as 41⅔ degrees, by which the equator declined from the vertical point of Rome — that is, the latitude of the city of Rome, which Ptolemy, more recently, defined as 41° 40′. But the observation of more recent men, as Erasmus Reinhold reports, shows the same latitude in this our age to be 41 degrees and a sixth, so that you may be in doubt whether you would prove that half a degree has been lost through the centre of the world or through a tilting of the Earth.* Stadius thus holds that the altitudes of the pole have diminished from Ptolemy to these times, whereas Domenico Maria and Maginus thought they had increased. In so far as his opinion rests on the unequal motion of the fixed stars, we have already refuted it, and Penna's, in the scholia of chapter 3; the rest will be refuted shortly, once we have reviewed the opinions of others.

IX. After this, Christoph Rothmann, mathematician to the Landgrave of Hesse, reported to Tycho, as Tycho himself relates in volume 1 of the *Progymnasmata*, p. 684, [Margin: Rothmann's opinion on the changed altitude of the pole.] *that he had sometimes noticed that the altitude of the pole shows itself different by one or two minutes in summer from what it is in winter; and that the intervals between certain fixed stars, especially those separated by a great distance, come out different at one time from another, so that they too undergo a variation of about two minutes. And he thought it was made probable from this that the Earth does not perpetually and immovably occupy the centre of the universe.* Finally, Pierre Gassendi, at the end of his *Judicium de novem stellis circa Iovem visis* [Judgement on the nine stars seen around Jupiter], relates a certain observation made by Alexander Calignonus, which, if it were true, would be an argument that the

Earth librates in some meridian and by its libration varies the altitudes of the pole. [Margin: Alexander Calignonus's observation on the change of the plumb line.] For he says that Calignonus hung a plumb line from a height of thirty feet, enclosed in a tube so that it would be safe from movements of the air; that he fixed a point beneath the plumb-bob, and beneath that downward-pointing point, when the plumb line was at rest, set another point standing vertically and fixed in a cube. With these prepared, he observed that the point of the plumb line moved for six hours from north to south, but curving towards the east, and for six hours from south to north, by a path curved towards the west; and that it reached the limit of its excursion towards the south at noon itself, and again at midnight. From this observation, kept up for a month, Calignonus concluded that the Earth has a certain motion from south-west to north-east [ex Africo in Cęciam], and from north-east to south-west, and that the ebb and flow of the sea's tide is to be ascribed to this motion rather than to the Galilean motion of the Earth. Gassendi, though he suspends his assent, does not oppose this observation so far as not to wonder whether observers of the heavens should be warned that, in taking the altitude of the pole from the meridian altitudes of the Pole Star, they should beware of those hours at which the altitude of the culminating star is not the same. For if the Earth nods in this way, the altitude of the stars is not the same at midnight and at the sixth hour; but in this century the greatest altitude of the Pole Star is to be observed in Europe around the sixth hour of the evening, and the least around the sixth hour of the morning.

X. We have thus found three opinions so far on the change of the altitudes of the pole. [Margin: Summary of the three opinions brought forward.] The first is of a change that is secular, that is, not perceptible except over the lapse of centuries — whether it increases these altitudes, as Domenico Maria, Giordano Bruno and Maginus held, or decreases them, as Io. Stadius held. The second is of an annual change, owing to the Earth's annual approach to and withdrawal from the fixed stars; this was Christoph Rothmann's. The third is of a diurnal change, owing to a libration of the Earth from south-west to north-east and back, returning to the same position twice a day; Alexander Calignonus affirmed it, and Gassendi did not deny it. We now undertake to refute these in order, and much more accurately than was done against Domenico Maria, Stadius, Maginus and Rothmann by William Gilbert in *De magnete* book 6, chapter 2; by Tycho in volume 1 of the *Progymnasmata*, p. 684, and in the *Astronomiae instauratae mechanica*, page 8 before the end, and also in a letter to Io. Antonius Maginus dated 1590 December 1, by the old calendar [calendis Decembris anni veteris], which we have at the front of Maginus's own Tables of Directions of the primum mobile, p. 82; by Kepler in the *Astronomiae Pars Optica*, p. 148; and by Villebrordus Snellius [Willebrord Snel], *Eratosthenes Batavus* book 1, chapter 8, where, speaking of Domenico Maria contriving great things out of a very few slight observations, he says: *Here he makes us an elephant out of a gnat; for if he had examined Ptolemy a little more carefully, he could have*

done with this prognostication without any effort. [Margin: Authors asserting the unchangeability of the altitudes of the pole.]

XI. First, then, against Domenico Maria and his followers there stands the magnetism of the Earth, which, as Gilbert, Cabeo and Zucchi, already cited above, contend, requires that its axis remain immovably in the same position towards the same points of the heaven, and therefore that the altitudes of the pole do not vary. [Margin: 1st argument for the unchangeability of the altitudes of the pole.] Next, for a just comparison to be made between the altitudes of the pole of one and the same place taken in antiquity and taken recently, both would have to be most exact. [Margin: 2nd argument.] But it is well enough established that those taken in antiquity were not so precise, for many reasons. First, because the parallax and refraction of the Sun were neglected, not only in the Sun's solstitial altitudes but also, and chiefly, in measuring the longest and the shortest day of the year — the measure from which, as is established, Ptolemy in the *Geography* determined very many altitudes of the pole, that is, latitudes of places. For the horizontal refractions apparently increase the length of the day: by raising the Sun they make it seem to rise earlier and set later than the obliquity of the horizon and the Sun's declination would require, and this more in winter than in summer. It could therefore happen that differences in the refractions prevailing at different times on the same horizon produced a difference in the altitude of the pole — a matter indicated by Gilbert, book 6, chapter 2, illustrated by Kepler in the *Optics*, p. 148, and not omitted by Tycho. Moreover, when the ancients deduced the altitude of the pole from the ratio of the equinoctial shadow to the gnomon, then, even granting that the end of the shadow and the right angle of the gnomon had been applied most exactly, the equinox still did not fall at noon, and the variation of the declination on the equinoctial days was large; nor was even the day due to the astronomical equinox certain to the observers. At any rate, in all these points there lurks some suspicion of error, which makes those altitudes uncertain. But the principal fault in those observations was that the altitude of the Sun's upper limb was used in place of the altitude of the Sun's centre — the upper limb, of course, being what bounds the end of the shadow with its ray — when the Sun's apparent semidiameter ought to have been subtracted from that altitude. We have shown this by many examples in our Geographical book, and will make it plain with some a little below; and Snel noted this very fault in those observations in his *Eratosthenes Batavus*, book 1. Suppose, then (as could easily happen), that the moment of the equinox was mistaken by a whole day, and that the observation of the equinoctial shadow was made on March 25, which the civil calendar marked as the day of the equinox, but that the equinox fell at noon on the 24th or the 26th. Here, then, is an error of 24 minutes, since it is established from the table of solar declinations that on the days nearest the equinox the Sun's declination varies by a whole minute every hour. Add to this error the error of about 16 minutes contained in the Sun's apparent semidiameter: do you not see that an error of 40′ could arise from this in estimating the altitude of the

pole — or of a whole degree and more, if the observation was made two days before or after the true equinox? And what if Ptolemy determined some of these by conjecture from the position of the regions, as Gilbert suspects in *De magnete* book 6, chapter 2, saying: *Since Ptolemy received only certain latitudes from Hipparchus, and did not observe them himself at most places, it is likely that, knowing the position of the regions, he estimated the latitude of the cities by probable conjecture only, and then committed it to his tables. So one may see in our own Britain that the latitudes of cities are wrong by two or three degrees, as experience teaches. Therefore no new motion should be introduced on account of these errors, nor should the Earth's renowned magnetic nature be disfigured by an opinion so lightly conceived.* [Margin: The Ptolemaic altitudes of the pole are very erroneous.] And this was precisely the reason why Tycho, in the *Astronomiae instauratae mechanica*, page 8 before the end, earnestly wished that the Republic of Venice would send skilled men to Alexandria in Egypt to take the polar altitude of that city exactly — both for other purposes, and so that, by comparing it with the altitude once taken by Ptolemy accurately enough, as it is fair to believe, it could be determined whether or not the altitudes of the pole change with the lapse of time. For he judged that the other altitudes, which Ptolemy did not observe but handed down on others' authority or from his own conjecture, were by no means to be trusted. And our Clavius, too, in the *Sphaera*, page 284 in my copy, declares that the latitudes of places recorded by Ptolemy not rarely depart from the truth by one or two degrees. Yet not even the more recent astronomers have always been so exact in this business as to incur no error even of a minute, as we shall soon see concerning the altitude of the pole at Rome. The altitude at Paris is also worth noting: in observing it, Orontius found 48° 40′, Vieta [François Viète] 48° 49′, Gassendi and Hortensius [Martinus Hortensius] 48° 42′ or 43′, Hérigone 48° 55′, Father Georgius Furnerius [Georges Fournier] 48° 50′ — whether this arose from the differing size, placement and use of the instruments, or from parallax, or from some other source. [Margin: The altitude of the pole at Paris varies.] It is no wonder, then, if Rothmann could obtain an altitude of the pole at Kassel differing by two minutes at different times of the year; and Tycho, in volume 1, p. 684, rightly reproved him for not hesitating to build a motion of the Earth on this difference, which could easily have arisen from error. [Margin: Rothmann reproved by Tycho over the altitude of the pole.] This is all the more so since it is established from the Hessian observations published by Villebrordus Snellius that, because the instrument was badly placed, the altitude of the pole at Kassel was found to differ from itself by several minutes. The same thing happened to Tycho with the altitude at Prague, as the same Snel reports in the Bohemian observations: at first he found it 50° 6′, and Longomontanus, Kepler and Lansbergen set it at that figure in their catalogues; but afterwards he found 50° 4′ 30″. [Margin: The altitude of the pole at Prague.]

XII. But grant that the observations of neither the ancients nor the moderns were erroneous in observing the altitude of the pole. Even so, for Domenico

Maria's divination to be true, all, or very many, of the altitudes of the pole observed by the ancients would have to be found increased when compared with the more recent ones — and by 70 minutes at that, from Ptolemy to the year of the Lord 1490. [Margin: 3rd argument against Domenico Maria.] But this is false. Some have rather diminished, some are found to be of the same quantity as of old, and some have indeed increased, but by many fewer, or by more, minutes than 70′. This must be shown by several examples, beginning, as is fitting, with Rome.

At Rome, then, around the times of Augustus, the equinoctial shadow was found to stand to the gnomon in the ratio of 8 to 9, as Vitruvius, book 9, chapter 8, and Pliny, book 2, chapter 72, expressly affirm. From these two sides, by the rules of rectilinear right-angled triangles, the meridian altitude of the Sun's upper limb at the equinoxes is found to have been 48° 22′; but when the Sun's semidiameter, about 16′, is subtracted, 48° 6′ remains. [Margin: The altitude of the pole at Rome examined.] Such, then, will have been the Sun's meridian altitude at Rome at that time, if we neglect the parallax, which for us does not exceed 30″, and suppose that the observation chosen out of many for that ratio of 8 to 9 was the one in which the equinox took place at noon itself or very close to it. Consequently the complement of the altitude to the quadrant, that is, the altitude of the pole, will have been 41° 54′. Ptolemy, however, puts it at 41° 40′. The reason is that, as is clear from the *Almagest* book 2, chapters 5 and 6, he deduced the meridian equinoctial and solstitial shadows from the altitude of the pole, and conversely the altitude of the pole from these shadows, without taking any account of the Sun's semidiameter or making any mention of it. He therefore used the equinoctial shadow cast by the upper limb, which gives an altitude of the limb of 48° 22′, or in round numbers 20′, and took as the altitude of the pole its complement, 41° 38′, or in round numbers 40′. If, then, the Sun's semidiameter of 16′ is added to this altitude of the pole, the altitude of the pole comes out, as above, at 41° 54′ or 56′; and Ptolemy cannot be reconciled with Vitruvius and Pliny in any other way. Now Clavius, in the *Sphaera*, puts it at 41° 56′ from more recent observations, and Latinus Ursinus [Latino Orsini], in part 3 of the *Radius Latinus*, chapter 5, puts it at 41° 54′ from his own observation — the same figure that Bellarmatus [Girolamo Bellarmato] and Maginus also give in their geographical tables. Granted, Tycho, in the letter to Maginus found on folio 81 of Maginus's own *Directions*, infers it to be 42° from the observation of Regiomontanus made when he was at Rome, which is the figure the Alphonsine and Rudolphine Tables give. It is therefore as great now as it was of old, and it has not increased, as Domenico Maria would have it, by a sensible and evident difference, if we follow Ptolemy corrected and reconciled with Vitruvius and Pliny; much less has it increased by 70′. [Margin: Ptolemy's errors in the altitudes of the pole.]

But if Domenico Maria contends that Ptolemy is not to be corrected and that his numbers are to be taken as they stand, I in turn shall show either that Ptolemy contradicts himself or that the altitude of the pole at Rome was not

smaller in the past than it is now. For in the 6th table of Europe Ptolemy says that the longest day observed at Rome was $15^h\ 5^m$. The semidiurnal arc was therefore $7^h\ 32½^m$, or 113° 7′, and its supplement to the semicircle gives the lower angle at the pole of the world, 66° 53′. With this, and with the complement of the Sun's greatest declination, which in truth was then too 66° 30′, as I showed in Book 3, chapter 27, there follows, by the second rule of right-angled spherical triangles, an altitude of the pole at Rome of 42° 5′. But if, on the strength of our own observation, we reduce the semidiurnal time by about 4 minutes on account of the refractions that increase it — that is, increase the lower angle at the pole of the world by one degree — the altitude of the pole comes out at 40° 53′, which contradicts Ptolemy, who puts it at 41° 40′ in his Tables. Indeed, if we used the obliquity of the ecliptic that he asserts, 23° 51⅓′, the altitude of the pole at Rome would come out at 40° 25′, which contradicts Ptolemy much more. So it does not serve Domenico Maria to cling to an uncorrected Ptolemy.

But here is another argument for applying a correction to Ptolemy because he neglected the Sun's semidiameter, and this in the altitude of the pole at Alexandria in Egypt. There, on the testimony of Vitruvius, book 9, chapter 8, the equinoctial shadow was found to stand to the gnomon as 3 to 5. Now let it be: as 3 is to 5, so is the whole sine of seven ciphers to 16666666, which is the tangent of 59° 2′; and this gives the altitude of the Sun's upper limb, namely 59° 2′. If you subtract from it the Sun's semidiameter of 16′, there remains 58° 46′, and so the altitude of the pole at Alexandria is 31° 14′. [Margin: The altitude of the pole at Alexandria examined.] But if the Sun's semidiameter is not subtracted, the altitude of the pole would be 30° 58′, exactly what Ptolemy gives in book 5 of the *Almagest*, chapter 13, and in book 4 of the *Geography*, table 13. It is clear, then, that he erred by 16 minutes through neglecting the Sun's semidiameter. Into this error — what is more surprising — fell not only Gemma Phrysius, in chapter 21 of the *Radius Astronomicus*, but also Snel, in book 1 of the *Eratosthenes Batavus*, chapter 8: from the ratio of 3 to 5 they inferred an altitude of the Sun of 59° 2′ and of the pole of 30° 58′, when that was the altitude of the limb, not of the Sun's centre. [Margin: The slip of Gemma Phrysius and Snel.] I found that a man here in Bologna, otherwise very learned in geometry and astronomy, had fallen into an error similar to this: measuring the altitude of the ☉ from the turned shadow, and subtracting the semidiameter of the ☉ from the altitude of the lower limb when he ought to have added it, he differed from us by a full 32′.

XIII. But so that the inconstant difference between the altitudes of the pole handed down by Ptolemy and those observed more accurately in these latest times may appear, I shall select the following from my Geographical book, and so make the falsity of Domenico Maria's opinion manifest.

Ptolemy's Altitudes of the Pole compared with the Observations of the Moderns.

Places	Ptolemy	Others	From the observations of
Aix [Aquae Sextiae]	43° 45′	43° 33′	Petrus Gassendus [Pierre Gassendi]
Avignon	44° 0′	43° 53′	Anton. Franc. Payen
Augsburg [Augusta Vindelicorum]	46° 20′	48° 22′	Paul Hainzel
Barcelona	41° 0′	41° 26′	Father Io. Bapt. Cysatus [Johann Baptist Cysat]
Bologna, Bo[?]onia Felsina	43° 30′	44° 29½′	Our observations
Florence	43° 0′	43° 40′	Egnatius Dantes
Genoa	42° 50′	44° 27′	D. Vincentius Reinerius [Vincenzo Renieri]
London	54° 0′	51° 32′	Vrichtus and Brichtus
Leiden [Lugdunum Batavorum]	53° 20′	52° 10′	Villebrordus Snellius [Snel]
Majorca	39° 15′	39° 35′	D. Vincentius Mutus [Vicenç Mut]
Marseille	43° 6′	43° 20′, or 17′	Gassendi or others, from Raynaudus's letters
Messina	38° 30′	38° 11′	D. Carolus Vintimilius [Carlo Ventimiglia]
Modena	43° 40′	44° 40′	Father Franc. M. Grimaldus [Francesco Maria Grimaldi]
Palermo	37° 0′	38° 10′	D. Carlo Ventimiglia
Paris	48° 30′	48° 50′	Father Georges Fournier
Parma	43° 30′	44° 51′	From our observation
Pisa	42° 45′	43° 28′	D. Vincenzo Renieri
Ravenna	44° 0′	44° 24′	From ours
Reggio [Regium Lepidi]	43° 30′	44° 44′	D. Antonius Rocca [Antonio Rocca]
Toulouse	44° 15′	43° 30′	Io. Fernelius [Jean Fernel]
Valencia in Spain	39° 0′	39° 30′	Hieronymus Munosius [Jerónimo Muñoz]
Lisbon [Ulyssipo]	40° 10′	38° 40′, or 38′	Nonius [Pedro Nunes]; ours

XIV. So much against the first opinion, which held that the altitudes of the pole vary, but only after many years, by a kind of secular change — and even if that were granted, nothing would follow for the annual motion of the Earth. Next came the second opinion, Rothmann's, which asserts that the altitudes of the pole vary every year because of the Earth's annual motion, so that the highest value taken in winter is one thing and that taken in summer another. Since, however, this does not exceed 2′, it is very easy to put that variation down to the instruments, or to the use of the instruments, as we have already said. Yet Tycho, in volume 1 of the *Progymnasmata*, p. 685, judged that if it were admitted, the annual motion of the Earth could probably be inferred from it. Galileo, by contrast, in Dialogue 3 on the system of the world, from p. 276 of the Latin edition, teaches that no change in the pole would be detected from this, because the Earth's axis does not look to the fixed pole itself in the heavens but to one point after another; but that a change would appear in the apparent altitude of some fixed star, and in its distance from the pole, if Copernicus admitted any sensible parallax in the fixed stars on account of the diameter of the annual orb. On p. 282, however, he tries to show that such a change, caused by the annual motion, will not appear in any fixed stars that lie in the ecliptic — granted that they will appear larger than themselves as the Earth approaches them; whereas in stars placed outside the plane of the ecliptic a

change in meridian altitude will appear, greater the farther they stand from the ecliptic, but a change in apparent magnitude correspondingly smaller. Thus if some star is very close to the pole of the world, it will appear of the same magnitude all year round, but to someone observing that same star once and then again after six months, the difference in its elevation above the horizon will appear the greater, the greater the ratio of the annual orb to the eighth sphere. [Margin: Galileo's doctrine of the change in the altitude of the fixed stars due to the annual motion of the Earth.] "But Galileo errs here," says Father Francesco Maria Grimaldi, "for, to take an example, for an inhabitant of the right sphere, a fixed star at the beginning of ♋, even though it lies in the ecliptic itself, will have a much smaller meridian altitude when the Earth is placed at the beginning of ♋ than when it is placed in ♎ or ♈, if the annual orb is supposed very large. Indeed, while the Earth is under ♈, that fixed star will rise for this inhabitant at midnight itself, and after 6 hours will be on the meridian, if the annual orb bears no ratio to the sphere of the fixed stars; but quite otherwise if it bears a large one — as will be readily clear to anyone who examines a Copernican sphere." [Margin: Galileo's slip.] But since Copernicus, as Tycho also noted above, knew that these differences do not appear, and that, granted the Earth's annual motion, the unchangeableness of these altitudes and magnitudes could not hold if the ratio of the diameter of the annual orb to the diameter of the fixed stars were sensible, he therefore laid down that this ratio is insensible, and that the diameter of the annual orb is like a point compared with the diameter of the sphere of the fixed stars.

XV. To Alexander Calignonus's experiment we reply with an experiment of our own that came out quite the contrary. We hung a plumb line from a similar height in a room closed on every side, and drew a small line, perpendicular and very fine, on a small white board near the bob, against the silk thread. Within half an hour the plumb line came so completely to rest that the thread coincided exactly with the line and did not nod this way or that with any sensible wobble — even when it was watched from below, with a mirror placed underneath and a point fixed into the bob, to see whether any motion could be detected in it. I tested this more than once, formerly at Ferrara and afterwards at Bologna, with Father Francesco Maria Grimaldi as witness. So I cannot but believe my own eyes; and perhaps the opposite happened to Calignonus because the plumb line's thread was twisted, or because the place he had hung the plumb line from trembled, or for some other cause. But see what I said about these matters in Book 2, chap. 21, scholia 2 and 3. Yet even if we granted him this, what could be inferred from it would be at most a diurnal libration, not an annual motion of the Earth. Let Argument 2 now run as follows, with its reply.

[Margin: Argument 2 and its reply.]

XVI. *The altitudes of the pole change, either over a long course of centuries, or yearly, or daily; therefore the Earth moves with an annual motion.*

The reply is, first, to deny the antecedent: as regards the secular change, this is clear from what was said from number 11 to 13 inclusive; as regards the

annual, from the end of number 11 and from number 14; and as regards the daily, from what was said in number 15.

I reply, second: granting the antecedent as to its first and last part, I deny the consequence. For those changes would not establish an annual motion of the Earth in the ecliptic, but some libration, requiring for its period either many centuries, or a day, or only half a day.

CAPVT XII. Proponitur & Diſſoluitur Argumentum pro Motu Annuo Terræ à motu Macularum Solis deſumptum; eaq. occaſione Doctrina de his Maculis à Galilæo & Scheinero tradita, in Epitomem redigitur; quo luculentiùs Argumentum hoc eiuſq. ſolutio declarentur.

CHAPTER XII. The Argument for the Annual Motion of the Earth taken from the motion of the Spots of the Sun is set out and refuted; and on this occasion the Doctrine of these Spots handed down by Galileo and Scheiner is reduced to an Epitome, so that this Argument and its solution may be made clearer.

I. Galileo, in Dialogue 3 on the Ptolemaic and Copernican system of the world, tried to use the very spots of the Sun to besmirch and destroy the Sun's annual motion and to fasten an annual motion on the Earth. Indeed, he counted this among the three strongest arguments for the Earth's motion, in Dialogue 4, on the penultimate page, where he says: *From the conversations held over these four days we therefore have notable testimonies for the Copernican system, of which these three — taken first from the stations and retrogradations of the planets and their approaches to and elongations from the Earth, second from the revolution of the Sun upon itself and from what is observed in its spots, third from the ebb and flow of the sea — seem to have a most evident force of proof.* Since, I say, he attributes so much to this argument, we must, lest we seem to have failed in a task once undertaken, search this ford more diligently; and, as the opportunity offers, explain the motion of these spots here, where it is easier to understand for readers now practised, than it would perhaps have been in Book 3, chap. 3.

I. First, then, Galileo, as he himself relates in the history of the Solar Spots, in three letters to Marcus Velserus [Markus Welser] written, in which that history is comprised. Velserus had forewarned him of these observations, published by our Apelles, who was then hiding behind the picture — that is, by Christoph Scheiner, who for the time being suppressed his name at the order of Father Theodorus Busaeus, the Provincial, who did not want these novelties, not yet fully explored, to be made public by our men. In that history, I say, in letter 1, Galileo approves Apelles's opinion on the nearness of the spots to the Sun and on their real existence, because of the imperceptible parallax between them and the Sun. [Margin: Galileo's opinions on the spots of the Sun, from his letters.] But Apelles had said that they move around the Sun from east to west — considering, that is, the motion visible to us. [Margin: From letter 1.] Galileo grants this, if their whole revolution around the Sun is not considered;

but if it is considered, he says they move in the way that Venus and Mercury move around the Sun, namely from west to east — which is true if the motion is regarded above, that is, in the Sun's hidden hemisphere. He adds that the evening spots, observed near sunset, change their position daily and descend from the upper parts of the Sun towards the lower, whereas the morning spots ascend from the lower parts of the Sun towards the upper. He denies that their substance is very dense, and says instead that it is like smoke or clouds; he likewise denies that they are fixed or wandering stars; finally, he denies that they move in circles separate from the Sun, since otherwise they would have to pass more quickly than Mercury does beneath the Sun — and yet Mercury crosses the disc of the Sun in about six hours, whereas the spots stay beneath it for many days.

III. In letter 2, to the same M. Velserus, he confirms some things said in letter 1, and affirms the following propositions about the solar spots. [Margin: From letter 2.] Besides the disordered and irregular motion by which several spots flow together into one, or one disperses into several, they have another motion, ordered, common and greatest, by which they are carried round uniformly, in lines parallel to one another, by the globe of the Sun to which they are contiguous; so that this rotation of the Sun about its centre, and of the spots about the globe of the Sun, completes its period or revolution in about one lunar month; and this rotation is like the turning of the planets in their orbs, inasmuch as they revolve from west to east. He confirms their contiguity with the Sun, and their rotation with it, from the fact that when they appear or disappear near the edges of the Sun they look of small length, though keeping the same breadth, but in the middle of the solar disc they look longer. Further, he says that the multitude of spots does not appear over the whole disc of the Sun, but only in a certain middle zone of the disc, which does not exceed 56° or 58° of the 360° that make up the circumference of the great circle on the Sun's globe. Thus, just as the greatest declination of the planets from the equator does not exceed 23½° towards north or south in the Sun, but in the other planets, which have latitude, does not exceed 28° or 29°, so the greatest declination of the solar spots from the middle of the Sun's disc does not exceed 28° or 29° of the solar circumference towards south or north. From this he deduced that there are two poles on the surface of the solar globe, about which that rotation takes place, while the other points describe the circumferences of parallel circles, of which the greatest is the one standing equally distant on either side from those poles. After demonstrating by several arguments, in the same letter 2, that these spots are contiguous to the Sun, he teaches that many of them return and travel again along the same parallel. Towards the end of the letter he teaches a method of observing the spots; and from their sudden generation and destruction on the disc of the Sun, before they complete their turning from limb to limb, he confirms both the fluidity and the corruptibility of the parts of the heavens.

IV. Finally, the third letter teaches that hardly one spot in a thousand observed is found to cross the zone already mentioned, and that they do not decline from the middle of the Sun beyond 29° or 30°. [Margin: From letter 3.] Their rectilinear motion, he says, is an argument that they move around an axis perpendicular to the ecliptic. And because Apelles had said that a certain spot passing through the Sun's great circle appeared on the Sun's disc for 16 days, another in a smaller parallel for 14 days, and some for only 9 days, Galileo denies that this diversity is possible. He says that all the spots that complete their course, and are not extinguished before their apparent setting, stay an equal time on the disc of the Sun, a time he defines as a little longer than 14 days in one hemisphere of the Sun; and he proves this from his own observations. He also teaches that if one of the spots crossed the disc of the Sun in 16 days, and another, standing as far as possible from the middle, namely at 30°, crossed it in 14 or 13 days and 20½ hours, the semidiameter of the aetherial sphere in which those spots revolved would be twice as great as the semidiameter of the solar body. He confirms besides that the spots are on the very surface of the solar globe and are carried round by its rotation, from the faculae, brighter than the rest of the Sun itself, that appear on it and move with the same motion as the spots; for it is not credible that any body brighter than the Sun should be found outside the Sun. He adds that we can imitate the production and destruction of the solar spots if we throw wax, pitch or bitumen on a red-hot iron: for a black spot then forms on the iron, and smoke rises from it, spreading out into various figures. Many spots, he says, are suddenly born and die away in the very middle of the Sun; yet they are not within the Sun's substance, as if they were its lakes or caverns. This, in summary, is Galileo's doctrine of the spots of the Sun, reduced to an epitome from those three letters, with many other things deliberately left out that have no bearing on our argument but concern Venus or Mercury seen below the Sun, or the spots of the Moon, or the satellites of Jupiter, or the reflection of the Sun's light from the Earth. Let us now see what the same author taught, under the persona of Salviati, about the motion of these spots in Dialogue 3 on the system of the world.

V. In that Dialogue, then, on p. 337 of the Italian but p. 255 of the Latin version, he affirms that the Sun itself, by its spots, is a most splendid witness, beyond all exception, for the Earth's annual motion. [Margin: Galileo's doctrine of the motion of the spots of the Sun, from Dialogue 3.] He affirms also that he was the first discoverer and observer of the solar spots, as of all the other celestial novelties, when he was professing mathematics at the university of Padua in the year 1610; that he discussed them with certain persons still living at Padua and Venice; and that he was the first to assert, from the sudden eruption and dissolution of these spots, the alterability of the heavens. He relates further that he had once thought that these spots, being contiguous to the Sun or adhering to its surface, were carried round by its roughly monthly rotation in such a way that this rotation took place about an axis of the solar globe erect to the plane of the ecliptic: for the arcs that the spots described on the Sun's disc appeared

to the observer's eye as straight lines, parallel to the plane of the ecliptic. If any deviation from that straightness appeared, he judged that it did not lie in their essential and primary motion, but came from an accidental concourse of small spots into one larger one, or from the tumultuous breaking-up of one spot into several very small ones. He says, however, that having interrupted his observations of the spots and afterwards resumed them, he came upon a very large spot, dense and solitary, and observed its passage around midday over very many successive days. When he noticed that its path was curved, he at once conceived a great hope of deciding about the motion of the Sun or of the Earth from this motion, and, turning to his host Filippo Salviati, he expressed that hope in these words: *Ah, Filippo, a way seems to open to me from here to consequences of great moment. For if the axis about which the Sun revolves is not erect perpendicular to the plane of the ecliptic, but is inclined over it, as the curved path of the spot lately observed suggests, we shall take from it a conjecture about the state of the Sun and the Earth than which no other accident has ever supplied us with one firmer or more probable.* [Margin: Galileo now calls probable the conjecture that, at the end of Dialogue 4, he calls a most evident testimony.]

At Salviati's request, then, he sets out this conjecture in almost these words. If the Earth, he says, is carried with an annual motion along the ecliptic around the Sun, so that the Sun, remaining at the centre of the ecliptic, rotates upon itself about that centre — not about the axis of the ecliptic itself (which would be the axis of the Earth's annual motion) but about an inclined axis — then wonderful changes must be presented to us in the apparent motions of the spots, even if the said axis of the Sun is supposed to persist perpetually and unchangeably in the same inclination and to be directed always towards the same point of the universe. For if the terrestrial globe goes round the Sun with an annual motion, it will be necessary, *first*, that to us, who are carried round with it, the passages of the spots should sometimes — but only twice a year — appear to be made along a straight line; but at all other times along a curve. *Second*, during one half of the year the curvature of these arcs will appear to us inclined the opposite way from the other half: that is, for six months the convexity of the arcs will face the upper part of the Sun's disc, and for the other six months the lower. [Margin: The variation of the motion of the spots according to Galileo.] *Third*, since the spots begin to appear and rise to our eye on the left side of the Sun's disc, and cease or are hidden on the right side, the eastern terms, that is, the terms of first appearance, will for six months be lower than the terms of hiding, and for the other six months higher: that is, spots rising from higher points and descending from them will be hidden, as they proceed, at lower points. Only on two days of the year will these terms stand in equilibrium; after that balance the inclination of the spots' passage will begin to grow greater and greater, until after 3 months it becomes greatest, and then, decreasing over another 3 months, it returns to equilibrium. *Fourth*, on the very days on which the obliquity or inclination of the spots' path is

greatest, the paths will look rectilinear; but on the days of the equilibrium already mentioned, as curved as possible.

VI. To illustrate this doctrine with Galileo by diagrams, as far as can be done on a plane (globes would be more suitable), let O, in the following figures, be the centre of the ecliptic, or great orb, and also of the solar globe, whose whole hemisphere we may suppose is seen by us earth-dwellers because of its immense distance. About this centre let the circle ABCD be described, representing the horizon of the solar hemisphere, that is, the great circle that bounds the hemisphere of the solar globe visible to us and divides it from the invisible one.

Diagram. A woodcut of three circles set side by side across the left column, uncaptioned; the text calls them the first, second and third figures. The first circle carries a horizontal and a vertical diameter through the centre O, an inclined diameter, a solid line studded with dots (the path of a spot) and two dashed lines parallel to it; the second and third circles each carry a horizontal diameter, an inclined axis, and a dotted arc above the centre (the hidden or visible path of a spot), with a further inclined diameter in the third.

- First circle: E, A (top), L, G, M (upper right), D (inside, right of the horizontal diameter), O (centre), B, H, F, K (left, from top to bottom), C, I (bottom)
- Second circle: A (top), E, G (above the centre), O (centre), F, I (below the centre), C (bottom), B (left), D (right)
- Third circle: A (top), E, S (upper left of the centre), G, D (right), O (centre), N, I (lower right), F (left), B (left, beside the second circle's D)

And since our eye, no less than the centre both of the Earth and of the Sun, lies in the plane of the ecliptic, if we imagine the body of the Sun cut by the plane of the ecliptic, that section will appear to our eye as a straight line; let it be BOD. The perpendicular AOC drawn to it will be the axis of the ecliptic, about which the Earth's annual motion takes place. Let us now think of the body of the Sun, immobile about its own centre, as revolving upon itself not about the axis AOC, perpendicular to the plane of the ecliptic, but about the axis EOI, somewhat inclined to the ecliptic; and let this axis be fixed and unchangeable, that is, always keeping the same inclination towards the same points of the firmament and of the universe. In the solar horizon let a point F be taken, equally distant on either side from the poles E and I, and from it let the diameter FOG be drawn through O, perpendicular to the axis EOI: it will be the diameter of the great circle described about the poles E, I. Now if the solar horizon ABCD, just as it passes through the axis of the ecliptic AOC, also passes, with respect to us who move with the Earth, through the poles E and I, then the great circle whose diameter is FOG will stand erect at right angles to the circle, or solar horizon, ABCD, on which the ray from our eye falls perpendicularly at O. The same ray will therefore fall in the plane of the circle whose diameter is FOG, and its circumference will look to us like a straight line, and so will the motion of the spots along it, as is marked in the first figure by the line FOG; while the paths of other spots will appear to describe

other straight lines parallel to FOG, such as HL and KM. [Margin: Case 1: the rectilinear path, explained by figure 1.] The same will happen after the Earth, six months later, has come to the point of seeing the other hemisphere of the Sun, which was previously hidden from it, provided it is so placed that the solar horizon ABCD passes through the poles E and I. But since, because of the Earth's annual motion, the solar horizon changes continually and passes through the poles E and I only at the two times or moments already mentioned, it follows that only at those two moments of the year will the spots' path appear to us exactly rectilinear. Hence it also appears that, since the appearance and beginning of the motion from the side F proceeds towards G, for us observing at midday the path of the spots ascends from the left and lower part towards the right and upper part of the solar horizon. But if the Earth has now reached the diametrically opposite part, the passage will be from the left but upper part G, descending to the lower right, F; for in this second case you must imagine your eye placed not in front of this first figure ABCD but behind it.

VII. Now suppose that the Earth has left that position and after three months has completed a quadrant of the annual orb (look at the second figure), and that the plane of our meridian passes through the axis of the ecliptic AOC. [Margin: Case 2: the curvilinear path, set out by figure 2.] The axis of the Sun's revolution, with its poles, will lie in that same plane, one pole visible to us, call it I, and the other, E, invisible, that is, lying hidden in the surface of the solar hemisphere that is concealed from us. For since the axis EI is inclined towards us at its lower part, the great circle described about it will also be raised upwards for us, and will be such as is marked by BGDF. So if a spot rises at B, its path visible to us will appear curved, running along BGD, so that its convexity bends upwards towards the northern limb of the Sun — and with the greatest curvature, and in the hemisphere of the Sun visible to us; while the rest of the spots' path, which will be hidden, runs along DFB with its convexity turned downward. Conversely, if the Earth, moving on from here, completes a semicircle after six months, the pole of the solar axis visible to us will be E, and the path of a spot risen at B will be visible along the arc BFD, its convexity swelling downward towards the southern limb of the Sun, while the rest of the path, hidden from us, will run along the arc DGB. Finally, for us observing at midday, the terms of appearance B and of hiding D will be in equilibrium, that is, equally distant from C or A. And what I have said of a spot risen at B holds for all the others risen elsewhere, for they will describe arcs parallel to the arc BGD, or, after six months, to BFD. But suppose the Earth is outside the positions already mentioned, so that neither the solar horizon ABCD nor the meridian AOC passes through the poles E, I of the solar axis, as you see in the third figure, but the axis is EOI. Then the diameter of the great circle described about it will be FOG, and the circumference of the circle FNGS. So if the pole visible to us is E, the visible path of the spots will be the curve FNG, though not with the greatest curvature, and its convex side will bend downwards; nor will the terms of appearance F and of hiding G be in equilibrium, but F will

be below and G above. [Margin: 3. Figure, and explanation of the case [?].] Conversely, with the Earth diametrically opposite this position, and the pole I visible to it, the curvilinear path will run along the upper arc GSF, with the appearance at the upper point G and the hiding at the lower part F, but from left to right; for here too, in the second case of this third figure, you must imagine the observer's eye to be behind the disc ABCD.

VIII. These are the wonderful vicissitudes that Galileo divined, by his conjecture, would come about — provided, that is, that three suppositions are admitted: namely, that the Sun by its rotation carries the spots round with it; that its axis is inclined to the plane of the ecliptic, but with the same inclination remaining perpetually; and that the Earth is carried round with an annual motion about the Sun, which remains at the centre of the world. When Giovanni Francesco Sagredo asks whether such vicissitudes were afterwards actually observed, Salviati (who plays Galileo's part in those dialogues) answers that the observations were continued at different times of the year and that the outcome answered the prediction most exactly. Then Sagredo, turning to Simplicio, concludes (p. 260 of the Latin, but p. 344 of the Italian): *Sir Simplicio, if these things that Salviati has set out are true (and it is not right to doubt his assertions), the Ptolemaics and Aristotelians will need solid arguments, strong conjectures and very firm experiments, if they are to counterbalance an objection of such weight and not incur the final ruin of their opinion.*

But Simplicio replies, acutely and soundly, that even if the phenomena of the solar spots are saved once the Earth's annual motion and the other conditions mentioned above are granted, the argument still does not hold when converted — namely, that if such are the phenomena of the spots, the Earth moves and the inclination of the solar axis is fixed — unless it is demonstrated that those phenomena cannot be defended otherwise. For why could they not be saved with an annual motion of the Sun posited about an immobile Earth? Salviati then concedes that this can indeed be done, but says that one would have to admit many and continuous motions, by which the Sun's axis perpetually changes its inclination to the axis of the ecliptic, and on account of which that axis is bent from moment to moment towards different points of the universe; and that this axis must therefore have its own monthly revolution, distinct from the annual revolution — since once every year the whole variety of the spots' motion is completed exactly and recurs again — and that the axis must have a convertible inclination, so that it lies sometimes in the plane of the solar horizon, and the path of the spots is therefore rectilinear, sometimes in the observer's meridian but outside the horizon of the solar globe, and sometimes in yet other planes. But it is far more likely, says Salviati, that the axis of the Sun's rotation is single and has a fixed inclination to the plane of the ecliptic, that the Sun is moved by no other motion than a simple revolution of about 27 or 28 days about its own immobile centre, and that all the remaining vicissitudes of the spots come about through the single and simple annual motion of the Earth — rather than that, with the Earth standing still, the Sun and its axis should be

entangled in multiple motions. Therefore it is also more likely that the Earth, rather than the Sun, moves annually. [Margin: The Earth's annual motion is inferred from what has been said.]

IX. Struck by this argument among others, Pierre Gassendi, in Letter 2 of *De motu impresso a motore translato*, p. 148, did not hesitate to break out in these words: *It is remarkable that the paths of the spots, when the Sun is at the equinoctial points, describe as it were straight lines on its disc, and at the other points, especially at the tropics, curved ones; and that this cannot be saved more conveniently than on the ground that, while the Sun always revolves about the same poles, its own or the ecliptic's, and carries the spots along with it, the Earth places itself towards it — now, as it were, to the right or left at the equinoxes, now, as it were, above or below at the solstices — in such a way that, because of the constancy of its own axis already set out, it sees the spots proceeding across the Sun's disc not in one manner only, but with the variety of straightness and curvature already mentioned: so Galileo demonstrates.* [Margin: Gassendi's opinion on the Earth's annual motion, but his errors about the motions of the spots.] In these words a twofold error lies hidden. First, neither Galileo nor Scheiner, in their later work, admits that the Sun's rotation takes place about the poles of the ecliptic; otherwise the path of the spots would always appear rectilinear to us. Second, it is not true that their path is seen rectilinear at the equinoxes and most curvilinear at the solstices; on the contrary, it is seen rectilinear rather about the beginning of December and of June, that is, nearer the solstices, and most curvilinear about the beginning of March and of September, that is, nearer the equinoxes, as we shall presently relate from Scheiner's most certain observations. Now we must reply to the argument drawn from this motion, set out in form.

X. *It is more probable that the apparent motions of the solar spots come about through simpler and fewer motions than through more numerous and more composite ones. But if the Earth moves annually about the Sun, rather than the Sun about an immobile Earth, the apparent motions of the solar spots come about through simpler and fewer motions than if the Sun is supposed to move annually about an immobile Earth. Therefore it is more probable that the Earth, rather than the Sun, moves annually.* [Margin: The argument set out in form.] The MAJOR is clear from those most widely received propositions, rehearsed so many times in this section: namely, that GOD and Nature do not strive to do through more what can be done through fewer, and that consequently not even we are permitted to introduce into the nature of things a multiplicity of any entities whatever, still less of motions, without necessity. The proof of the MINOR is sufficiently indicated by comparing what was said in numbers 5, 6 and 7 with what was said at the end of number 8; and it will be confirmed from the change of the solar axis asserted by Scheiner and by others who explain these phenomena on the hypothesis of a resting Earth.

I reply, 1 and 2, in the same way as I replied to the major of Argument 1, which I set out in chapter 9, number 5: namely, by conceding the major if the simplicity of these motions, greater at first sight, neither involves other,

greater absurdities, nor saves other phenomena more evident to the senses than these, nor, when examined from within, involves many other motions along with it; but otherwise by denying the major of the syllogism, and its proof. [Margin: Replies 1 and 2.] And in the same sense as I denied it there, so I deny the minor here. For if the Earth is supposed to move and the Sun to remain at the centre of the world, certain phenomena more evident to the senses than the motion of the solar spots are destroyed; and in the Earth's motion there lie hidden very many other motions, multiple in kind and in number, most intricate, and no easier for the intellect to grasp than the motion of a solar axis that has a convertible inclination — since the same convertibility of inclination of the Earth's axis to the equator is involved in at least a twofold libration, one because of the precession of the equinoxes, the other because of the obliquity of the ecliptic, if we listen to Copernicus.

I reply, 3: granting the major, by denying the minor. [Margin: Reply 3 [?].] For if the Earth is supposed to move annually, it must also be supposed to move with a diurnal revolution about its own axis; and the phenomena of the spots further require a rotation of the Sun about its own axis, completed in, as it were, a monthly revolution; and these are three motions really distinct. But if the Earth is supposed to be at rest, a threefold motion of the Sun must likewise be posited: one, of the Sun's centre, which is at once annual and diurnal, along a spiral line, by which it therefore appears to move towards the east because, in its motion towards the west, it is slower than the fixed stars and the ideal motion of the primum mobile; the second, an annual motion of the poles of the solar axis about its own fixed axis, from west to east; and the third, that of the quasi-monthly rotation about another, mobile axis, from east to west, as we shall make plain from Scheiner in numbers 22 and 23. In either hypothesis, therefore, the multiplicity of real motions is equal; but in other respects there is a great disparity, on account of which the verdict seems rather to go for the Earth's rest.

Chiaramonti would reply, 4, in his *Defence of the Antitycho* [Defenſione Antitychonis], part 4, chapter 18, that the phenomena of the spots can be defended without any motion of the Sun's axis or annual revolution of the Earth, if the spots are said to move in their own epicycles. [Margin: Reply 4, Chiaramonti's, rejected.] But this reply supposes that the sunspots do not inhere in the very body of the Sun, which is false; and it moreover multiplies the motions to as many as there are spots, which favours Galileo's argument rather than destroying it.

XI. It is now time, towards the solution of the argument — for which I pledged my word in Book 3, chapter 3, at the end of number 8, and in the title of this chapter — for me to set out the phenomena of the solar spots, especially those that concern motion, more clearly than I did there, and to reduce to an epitome, for my reader who may perhaps lack books of this kind, what Scheiner first wrote about them in his *Apelles post tabulam*, and what he afterwards handed down to posterity in the *Rosa Ursina*, correcting himself,

and having by then become greater and more illustrious than himself, not to say than the Sun. For just as it is not to be counted a discredit to Galileo, so neither is it to Scheiner, if in their first observations, because of the novelty and intricacy of the phenomenon and the lofty and arduous contemplation that it otherwise demanded, they said some things less consonant with the truth; for afterwards, by correcting themselves, they earned the praise of astronomical sincerity. [Margin: Scheiner's encomium.] And Scheiner discoursed on this subject in the *Rosa Ursina* with so many and such exact observations, theorems and problems that he earned from Reinardus, or Renatus, Descartes [René Descartes] and from Johannes Hevelius the eulogy that nothing more accurate could have been done in this kind, or can be hoped for in future; and Father Nicolaus Zucchius [Niccolò Zucchi] of our Society, who was a constant witness of Scheiner's observations, and his encourager and helper, began, in his new and noble *Philosophy of Machines* [Philoſophia de Machinis], part 5, section 12, with this eulogy: *Let there first be presupposed here the canons of motion detected in the Sun in this our age, which Father Christoph Scheiner of our Society established by the most constant labour of many years, consulting the sky more often day by day, taking the rules of a better astronomy into counsel and wisely adding new ones; and later inspectors, not of books only but of the stars as well, have so confirmed them that from them even those who had formerly been his censors have corrected their errors and supplied their omissions, daring to contradict him in nothing; and most recently a man of the highest merit in astronomy has published the ordered courses of the sunspots over three years, whom I shall presently name, in his book* Selenographia. [Margin: Father Nicolaus Zucchius's eulogy for Scheiner.]

Doctrina Chriſtophori Scheineri de Maculis Solaribus, ex Apelle poſt tabulam latente, ſeu Epiſtolis ad Marcum Velſerum ſcriptis.

The doctrine of Christoph Scheiner on the solar spots, from his Apelles hiding behind the picture, that is, from his letters written to Marcus Velserus [Markus Welser].

[Margin: From letter 1.] XII. In the first letter, dated 1611 November 12, he relates that about eight months earlier, namely in March of the year 1611, he had turned a telescope, which enlarged an object almost eight hundred times in surface, on the Su- n, in order to explore its optical diameter in relation to the Moon, and on that occasion had seen certain blackish spots on the Sun, but had not then been concerned about them. Returning to this observation in the month of October, however, he at first suspected that those spots arose from some hidden defect in the air, or in the eye, or in the glasses of the telescope. But when, with different eyes called in as witnesses, and with the glasses exchanged and eight tubes used, the same spots appeared in the same order, position and number, he concluded that they did not arise from a defect of the eyes or of the glasses — nor from the air either: because they were moved with the motion of the primum mobile together with the Sun the whole day, whereas nothing in

the air is moved so constantly with such a motion beneath so tiny a portion of the sky as the Sun occupies; because they admitted no parallax the whole day, as they would have had to if they had been in the air near us, but appeared on the Sun's disc the whole day; because by a proper motion they turned, together with the Sun, from the Sun's eastern limb to its western over several days, until they vanished from sight; and finally because their phenomena were seen unchanged through mists and clouds. But since he then thought it unworthy to admit, in the Sun, a most luminous body, spots darker than some of those of the Moon, and since the same spots had not yet been seen to return, but always other and new ones, he judged that they are not turned round by the Sun and are not in the Sun, but go like stars, either below or around the Sun, with their own peculiar motions, and eclipse it for us. He admits, however, that not all the observations he had given Welser were at that time most exact, and that some, examined without the tube, appear simple which through the tube appear aggregated from many.

[Margin: From letters 2 and 3.] XIII. In the second letter, dated 1611 December 19, he reports that he had been intent on the conjunction of Venus with the Sun which, according to Magini's *Ephemerides*, was to begin on December 11 at the 11th hour of the night and last at least 40 hours; but Venus was not seen beneath the Sun, and from this he took the argument that in its superior conjunction it is carried above the Sun. In the third letter, written on December 26, he contends that the spots are not in the very body of the Sun. For since they appear beneath the Sun for less than fifteen whole days from their first appearance to their hiding, they ought, if they turned round with the Sun, to return after another fifteen days or a little later; yet in an experiment of two months none was seen to return. On the other hand, from the absence of any parallax from the Sun; from the fact that at their appearance and hiding near the Sun's limbs they grow thin; from the fact that several seen in the middle of the Sun appear to merge into one at the edges; and from their being fast in the middle of the Sun's disc and slow at the limbs, he gathers that they are both near the Sun and move around the Sun with their own motions; that they are certain heliacal bodies [ſidera quędam Heliaca], very dense, opaque and deep, inasmuch as they block the Sun's light; that they are wandering stars rather than fixed; and that just as there are satellites around Saturn and Jupiter, so there are around the Sun, etc.

[Margin: From letter 4.] XIV. In the fourth letter, written to the same man on 1612 January 16, from 30 observations made from 1611 December 10 to 1612 January 12, he affirms that the spots at their entry onto the Sun and exit from it are seen small, slower and blacker, and also joined together, but in the middle of the solar disc large, faster, less black and more separated from one another; that some, and very large ones, arise unexpectedly not at the limb but almost in the middle of the Sun's disc, or suddenly fail there before they reach the Sun's edge; and that some divide from one into two, and that almost in the middle of the Sun, or two merge into one, and so continue divided or joined until their

exit. He adds that their path appears parallel to the ecliptic, but he suspends judgement. He thinks it certain, however, that those which cross the middle of the Sun stay longer beneath the Sun than those far from the middle; and from this he takes a new argument that they are not fixed to the Sun as it revolves about its own centre: for one spot was seen beneath the Sun for at least 16 days, another, farther from the middle of the Sun, stayed beneath the Sun at most 14 days, and another 13.

[Margin: From letter 5.] XV. Finally, in the fifth letter, dated to Welser 1612 July 25, he first confirms that these spots are not an illusion or a mere spectre appearing through a defect of the eye, of the glass or of the air, since the same spots are seen by anyone's eye, in any situation under the open air, without glasses, in the same order, position and number, if a ray of the Sun, passing through a bare hole no bigger than a pea, is received in a darkened room on a paper parallel to the Sun's disc; and moreover because the same spots were seen and observed in different places — namely at Rome by Fathers Christophorus Gruembergerus [Christoph Grienberger] and Paul Guldin, distinguished mathematicians of the Society of Jesus, and by Galileo and others. From these and from his own observations he concludes, together with a certain Venetian who concealed his name under that of Protogenes, that these spots are real bodies, not in the Sun but near the Sun; that they are not spherical but of an irregular and variable figure, and therefore are not stars; yet that their interposition, unknown to the old astrology, does great harm, since in varying sublunary effects so many bodies, persisting so long beneath the Sun, have more power than Mercury alone, conjoined with the Sun and accustomed to stay beneath it for only a few hours. [Margin: A wound to judicial astrology from the spots of the Sun.]

Doctrina Chriſtophori Scheineri de Maculis Solis ex Roſa Vrſina in Epitomen Redacta.

The doctrine of Christoph Scheiner on the spots of the Sun, from the Rosa Ursina, reduced to an epitome.

XVI. In Book 1. Galileo, in the *Discourse on the Comet of the Year 1618*, p. 3, in the *Trutinator*, pp. 2 and 209, and in the dialogues on the system of the world, p. 337 of the Italian, sells himself as the first discoverer of the solar spots and of all the novelties of the sky, and accuses Apelles, that is, Scheiner, of theft, as if he had begun to observe the spots after seeing Galileo's writings about them and had then boasted himself their first observer. Scheiner therefore clears himself of this imposture. For he says that, with no prior rumour or indication, he began to observe them in March of the year 1611, while he was exploring the size of the Sun with a telescope; that afterwards, in October, he resumed the observations and informed Father Adam Tanner and Father Jacob Gretser of them, who passed this on to M. Welser, the Maecenas of all men of letters; and that Welser at last, by many letters, extorted from him the novelty

of this phenomenon and urged that it be published in print. This was done in the three earlier letters, dated in the year 1611, but under the feigned name of Apelles, because Father Theodorus Busaeus, the Provincial, did not wish these novelties, not yet sufficiently explored, to be published under Scheiner's own name. Welser, moreover, at once communicated Scheiner's letters to Galileo, on 1612 January 6. [Margin: Scheiner vindicated from the imposture of the theft of Galileo's observations.] But Galileo, replying to him on May 4 of the same year, affirms that he had observed the sunspots eighteen months before; and yet he produces no observation of the year 1611 with a diagram, but only those of the year 1612, from April 5. He ought, however, to have produced diagrams of spots observed in the year 1611 and at the beginning of the year 1612, as Scheiner did, so as to make it at least probable in this way that he had not been later than Scheiner in observing them. How, then, could Scheiner have stolen his own observations, earlier in time and made before April of the year 1612, from the observations of Galileo, which were published neither then nor afterwards? Galileo, it is true, excuses himself in that letter for not having published his observations earlier, because of suspense of mind and a fear of erring; but Scheiner had meanwhile published many of his propositions outright, and indeed ones contrary to what Galileo said. For Scheiner had already then said that the apparent motions of the spots are unequal, that their stays beneath the Sun differ, that some are blacker than the spots of the Moon, and things like these, the opposite of which Galileo affirms in his letters to Welser. Therefore, if Galileo wrote nothing about the spots of the Sun before he saw Scheiner's *Apelles post tabulam*, communicated to him by Welser — indeed settled nothing certain about them — whereas Scheiner had already then published in print many things, and things contrary to those which Galileo afterwards decided, how could Scheiner have stolen his observations from Galileo's writings? Next, it is false that Scheiner put himself forward in his letters as the first observer. For he did not deny there that others had observed the spots, nor did he arrogate to himself the invidious title of first discoverer; he only related what had befallen him unexpectedly, without any prior rumour or indication — which could have been true even if, a thousand years before, someone else had observed the same thing without Scheiner knowing it. Granted that he really was so, as the facts themselves, which say more than words, and the chronological comparison of other observations with Scheiner's, attest. To this I add that the *Rosa Ursina*, in which among other things the curvilinear motion of the spots is demonstrated, except at two times of the year, began to be printed in the year 1626 and was published in the year 1630, whereas Galileo's dialogues were published in the ye- ar 1632; and that, since in the third of them Galileo himself corrects himself and has admitted the curvilinear motion of the spots, which he had always previously thought rectilinear, some may suspect that he did this after seeing the *Rosa Ursina*, or after hearing what Father Scheiner had communicated at Rome to many outsiders, whom he admitted in good faith as witnesses and observers of his observations — especially since Galileo says in

that dialogue that the path of the spots must be rectilinear only twice a year, and for six months curved upwards and for the other six curved downwards, and affirms that the outcome answered this prediction of his, and yet does not dare to say in which months of the year these vicissitudes occur; which he certainly ought to have said, and would have said, if he had been able to determine these things from his own observations. It is therefore no slight indication that he inserted this correction of himself into the Dialogues not so much from his own observations as from seeing or hearing of other people's — which, however, I would not dare to affirm absolutely. Further, in this book Scheiner sets out the diagrams of observations he formerly made at Ingolstadt.

[Margin: From Book 2.] XVII. In Book 2 he teaches the use of the helioscope, which has coloured glasses, and of the telioscope, which has glasses or lenses that are not coloured; and he demonstrates from the foundations of optics the choice, testing and combination of lenses, and also the admission of the species through a bare hole and their transmission through the telioscope; the difficulties in observing spots and faculae, and the precautions to be taken; likewise the practice of drawing in the vertical line, or plumb line, and the ecliptic; and the times suitable for observing — although at the end of Book 3 he exhibits a new machine with which the solar spots are observed most easily.

[Margin: From Book 3.] In Book 3 he exhibits and explains the observations of the spots themselves, both his own and those of others. He warns in advance, on page 161, that the paths of the spots proceed obliquely to the ecliptic, from the north-east to the south-west, from the spring equilibrium, which occurs at the end of February and the beginning of March, up to the autumn equilibrium, which occurs at the end of August and the beginning of September; that in the first three months, March, April and May, the arcs of the paths are concave towards the south-east and convex towards the north-west; but that in the other three, later months — after the rectilinear station held at the end of May and the beginning of June, that is, in June, July and August — the concavities of the paths turn towards the north-west and the convexities towards the south-east. [Margin: When the motion of the spots is oblique to the ecliptic, and towards which quarters.] Everything happens the contrary way from the autumn equilibrium, which occurs at the end of August and the beginning of September, up to the spring equilibrium, which occurs at the end of February and the beginning of March. For in its first three months, September, October and November, the paths of the spots are concave towards the north-east and convex towards the south-west; but after the winter rectilinear station has been held at the end of November, the bends of the spots in December, January and February are concave towards the south-west and convex towards the north-east. Now this book contains observations made from 1618 to 1627, which are comprised in 71 images; and the number of observations shown in them amounts, by my reckoning, to 1425, the greatest part of which were made by Scheiner himself at Rome, and a few by others of our Society at Ingolstadt, Freiburg and Douai. Finally, he ends this book with a new telescopic and

heliotropic instrument by Father Grienberger, with which, without the angle of the ecliptic and the vertical, without drawing in a plumb line, and without the altitude of the Sun, the course of the spots, the position of the ecliptic and the other things necessary for this business are taken most expeditiously. To it are added demonstrations proving the instrument, devised by Grienberger himself, and a table of right ascensions and declinations for one quadrant of the ecliptic, at every 5′, constructed by the same man.

[Margin: From part 1 of Book 4.] XVIII. In part 1 of the fourth book Scheiner demonstrates the following propositions from the observations of Book 3. Chapter 1: "All the spots," he says, "that belong to the Sun never appear outside the Sun as long as they are visible, but rise with it and, when the diurnal motion is completed, set with it, from whatever part of the world they are viewed." And chapter 2: All the spots always appear to move from the eastern quarter of the Sun to its western. And chapters 3, 4, 5 and 6: No part of the heaven of the Moon, of Mercury or of Venus can cause any spot on the Sun by its interposition. And chapter 7: No spot or facula appears outside the visible disc of the Sun; the light of the solar faculae is stronger than the rest of the Sun's light and than the daylight spread through the aether; the faculae of the Sun are parts of the Sun, and since they move with the same motion as the spots, they prove that the spots are in the Sun itself, and therefore that the Sun turns about its own centre — otherwise, if the faculae were outside the Sun, those placed at the edges would shine outside the Sun. Hence epicycles and eccentrics proper to the spots and faculae are excluded, and from this alone it is gathered that they are not stars distinct from the Sun. And chapter 8: No spot has so far been seen to stand still on the Sun, or to go back, or to rush ahead, after so many years of observations, that is, from 1611 to 1627; from which it is confirmed that they are carried round by the Sun, and not by eccentrics or epicycles of their own. And chapter 9: The paths of all spots appearing at the same time appear, other things being equal, of the same kind and position — that is, all rectilinear, or all curvilinear and swelling with their convexity towards the same quarter; from which it is gathered that there is a certain motion universal to them all, from some common subject that moves them.

And chapter 10: All paths of the spots described yearly on the same parallels are sensibly similar to one another, and for the most part equal in time. That is, if, for example, on 1627 August 22 certain motions are described by a spot in a certain parallel of the Sun, then in 1628 too, on August 22, any spot that is in that parallel will describe a motion similar to the one already mentioned — curvilinear upwards, that is, if that one was curvilinear upwards — and so for past and future years. And chapter 11: All spots in parallels equally distant from the greatest parallel of the solar globe, and separated from each other by an interval of six months, have similar motions, but subcontrary in position and direction; and from this uniformity it is confirmed that they are moved with the motion of one universal subject. And chapter 12: The paths of all spots and faculae become sensibly rectilinear twice a year, namely once about the end of

November and the beginning of December, and again about the end of May and the beginning of June; and yet their paths are oblique to the ecliptic, and the time of the rectilinear stays beneath the Sun is about two weeks, or nearly 14 days. [Margin: When the path is rectilinear [?].] But the direction of the rectilinear paths near midwinter is from the south-east to the north-west, and of those near midsummer from the north-east to the south-west. And chapter 13: that the sphere in which the spots are thought to turn about the Sun is not larger than the Sun and homocentric with it; and chapter 14: nor heterocentric either; and chapter 15: nor larger than the Sun and of mixed eccentricity.

And chapter 16: All the paths of the spots turn from rectilinear to curvilinear, so that from about the beginning of December, through the three months December, January and February, they become daily more curvilinear, the arc swelling upwards towards the northern part of the Sun, and at the beginning of March they become most curved. From then on the curvature decreases more and more through March, April and May, until at the end of May they become sensibly rectilinear; from here they pass again into curvilinear paths, so that from the beginning of June their curvature grows continually, but downwards towards the south, through the three months June, July and August, at the end of which this curvature is greatest; and from the beginning of September the curvature decreases through three further months, September, October and November, until at the end of November the paths become rectilinear. [Margin: When the paths of the spots are curvilinear.] And in chapter 17 he gathers from the motions described that the motion of the spots is sensibly regular and ordered, uniformly difform, and about a mobile axis of the Sun, since the spots have appeared so constantly fastest in the middle and proportionally slower near the limbs, always from east to west, and with a reciprocal passage from rectilinear to curvilinear paths. The motion of this axis and of its poles from west to east — such that in one half-year one pole is in the part of the Sun visible to us and the other in the invisible part, and in turn, in the other half-year, the one that was visible is hidden — became known from the half-yearly contrariety of the course; and he gathers that from the ascent and descent of the axis and the poles comes the whole vicissitude apparent in the motion of the spots. And chapter 18: The paths of all the spots are rectilinear about the beginning of June, and most curvilinear towards the south about the beginning of September; but rectilinear about the beginning of December, and most curved towards the north about the beginning of March. And when they are most curved, they are then also in equilibrium, so that the terms of rising and of hiding, if the Sun is, at its centre, equally distant [Margin: When the curvature is greatest, and the equilibrium [?].]

from the horizon, or in the nonagesimal degree of the ecliptic, appear equally raised. And in Chapter 19: all the courses of the spots, if the annual and the monthly are considered each separately, are regular — that is, both the one produced by the Sun's poles as they describe small circles in their annual circling, and the one completed in about the space of a month; but if they

are compounded together, a certain irregularity arises from them, though it is imperceptible in a single passage. This he shows here for the rectilinear motion, and in Chapter 20 for the curvilinear. From Chapter 21 to 33, however, he shows that this irregularity comes from the refraction of the Sun's rays transmitted through glass lenses into the image of the Sun as it is received; and that this makes the spots appear to traverse greater arcs near the Sun's margins in less time, and smaller arcs near the middle of the Sun in more time; and that consequently no parallax of the spots, and no distance from the Sun, can be inferred from this irregularity. And in Chapter 34 he infers the true regularity of the spots' motion from corrected experiments, and that if they are in the Sun it must be regular; and that they are in the Sun he confirms by the arguments indicated above and by others still to be indicated. So much for the motion.

XIX. Now, in the same first part of Book 4, Chapter 35 deals with the increase and diminution of the spots and faculae — not only the optical or apparent, but also the physical and real. He says that the spots are on the physical surface of the Sun, as hills are on the surface of the Earth, which is not geometrically spherical; and that none of them moves about its own centre. Moreover, although all spots, other things being equal, appear optically smaller near the Sun's margins and larger towards the middle of the solar disc, yet sometimes, by physical increase, they appear larger near the margins, and, by physical diminution, near the middle, a compensation having taken place. [Margin: Increase and diminution of the spots.] And Chapter 36 shows that round solar spots, turned about the Sun, show to the sight, from the aspect, the same configuration on the Sun's hemisphere as they would display if they were similarly rotated about their own centre joined with the centre of the Sun. Chapter 37 asserts that physical increase and decrease have belonged to all the spots observed so far, but varied and successive; that the whole time of increase of one and the same spot is almost equal to its time of decrease, granted that the parts of this time do not have an equal or uniform quantity of magnitude, and that the times of increase of one spot are not equal to the times of increase of another; that the diameter of the spots is sometimes physically increased twofold, threefold and more; and that the increases of some quite often come about through the aggregation of several, just as decreases come about through disaggregation. Chapter 38 reviews the various ways in which physical augmentation can take place, and chooses as the most probable the one that occurs not by alteration or rarefaction alone, but by generation from the solar matter. Chapter 39 deals with the variable obscurity and clarity of the spots; and Chapter 40 with the nucleus of the spots, that is, the darker part in the middle. Chapter 41: that the spots cannot be shadows cast onto the Sun. Chapter 42: nor can they be a merely apparent opacity; but, Chapter 43, a true opacity is in them, and, Chapter 44, a true colour; and, Chapter 45, that this colour is probably blackness; Chapter 46, that it is physically intensified in the nuclei — about which, in Chapter 47, he disposes of many small questions, as in Chapter 48 of many about the light and clarity of the spots. [Margin: Obscurity, opacity, colour of the spots.] Next,

in Chapter 49, he deals with the shapes of the spots: that they are irregular and slender, and changeable from time to time. And in Chapter 50: that the physical surface of the Sun is alterable in many ways, by so great a variety of spots, faculae and shadows. And Chapter 51 teaches by many arguments that spots and faculae are generated and perish physically on the surface of the Sun. [Margin: Rising [?] and destruction of the spots, physical and astronomical.]

To understand these arguments, know that the astronomical rising of the spots is the name given when, because of the Sun's rotation, they begin to appear at its eastern margin, which for us northerners facing south is on the left; and astronomical setting is the name given when, because of the same rotation, they begin to be hidden at the Sun's western margin, on our right, and to traverse the upper hemisphere of the Sun, which is hidden from us. Physical rising, by contrast, is spoken of when they actually come into being anew, and therefore appear indiscriminately in any part of the solar disc, provided that part is visible to us; and physical setting, or destruction, is when they are extinguished and actually cease to be. With these premises laid down: the greatest part of the spots, says Scheiner, is born directly on the face of the Sun, far from the eastern margin, grows, and advances to the western limb until it sets astronomically. Likewise a great part of them rises astronomically, but before astronomical setting wholly fails physically. There are many, too, that have neither astronomical rising nor setting, but begin and cease to be on the face of the Sun between the two. Some, however, last from astronomical rising to astronomical setting, whether they are among those that arose physically in the hemisphere of the Sun hidden from us, or are those whose duration equals an entire rotation of the Sun of about 27 days. Rarely, moreover, does a large spot appear that is not born physically and does not fail without astronomical rising and setting; and spots of this kind grow with an escort of many, which nevertheless diminish after about two or three days, as the retinue of spots withdraws. Of the faculae, many perish after astronomical rising, before setting; many flash out anew on the face of the Sun without astronomical rising and set astronomically; some, though more rarely, are kindled and extinguished in the middle of the Sun without astronomical rising or setting. [Margin: Rising and destruction of the faculae.] Moreover, not all return after a rotation of 27 days, nor have any lasted so far that, in one whole year, not to say in several, they have returned through repeated rotations; therefore most perished before the end of the year. Besides, the secondary spots and faculae, which lie outside the middle zone of the Sun, are in perpetual change, and the Sun's surface is full of them. Finally, there have been some months in which no large spot appeared in the Sun. Are these not physically evident arguments of a real rising and destruction?

Again, in Chapter 52 he confirms the same generation and corruption from the fact that the greater number of spots are kindled into faculae. For this can happen neither by rarefaction alone, nor by their dispersal from the Sun brought about by rarefaction, as though that part of the Sun which previously suffered

eclipse from the spots now shines through; for in that way they would not appear at the margin of the Sun, if we suppose it, as the Peripatetics posit, both perfectly round and of uniform density and opacity. In that place he refutes at length certain people who say that the Sun has a thin crust, transparent in some places and opaque in others, in which it is enclosed, or who defend these phenomena rather forcibly in some other way, through translucency. Then Chapter 53 teaches that solar spots cannot be produced by the mere concourse of opaque parts, if hard orbs are supposed to rotate perpetually about the Sun. And that both they and the faculae are generated and corrupted, he again confirms in Chapter 54 from the manner of their beginning and ending. [Margin: Various modes of destruction and rising of the spots.] For some spots in the middle of the Sun's disc decrease in bulk and are attenuated into a shadow, so that they can scarcely be distinguished from the rest of the Sun's surface except by agitating the instrument; this shadow sometimes turns into a facula, sometimes vanishes without a facula, and sometimes splits into minute spots like black points, and these points, having advanced together in order over several days, pass off into faculae. Not rarely they leave behind them a trail and track, facular or shadowy; or they spread into one continuous shadow; or, as others vanish, they regain strength and grow into new spots, which again pass off into shadows or torches [faces] in a kind of reciprocal struggle. Often some spots seem to be overwhelmed on all sides by brighter matter until they become torches; and faculae are sometimes pure, sometimes surrounded by cloudy traces. But all the spots end at last either in faculae, or in shadows, or in the ordinary surface of the Sun. At their rising, moreover, many, from the thinnest shadows like spiders' webs, become thicker, blacken and grow; many bubble up from very small and separate ones and, having spread, make one continuous spot; many, from faculae joined with a shadow, degenerate into spots. Yet the beginnings are always smaller in intensity and extension, and the increases are completed sometimes after a few hours, sometimes only after whole days. Again, faculae are less stable than spots, harder to observe, and mostly larger than the spots from which they arose. Yet it is not in a continuous chain, as it were, of reciprocal rising and destruction that a facula comes from a spot, and from this facula a second spot, and from the second spot a second facula, and so on to infinity; this succession is often interrupted, and lasts only as far as the condition of the underlying matter allows. Who, having weighed all this, would not grant their physical rising and destruction? For what greater sign of such rising and corruption do we have even in the sublunary region?

XX. With these things established, he now shows in Chapter 55 that the true place of the spots and faculae is in the Sun itself or very near it, from the absence of any parallax. For they were observed at the same time by different observers in different places on the Earth and found in the same part of the Sun, as appears from the diagrams; and if any were observed at a different time, they were nevertheless found by the later observers to have advanced towards the western part of the solar disc by just as much as the proportion of the intervening time

to the rotation of about 27 days required. From this, at least, it follows that they are not so far from the Sun as to admit a parallax perceptible from us. [Margin: Place of the spots and faculae.] Scheiner affirms, moreover, that many observations were sent to himself and to Father Paul Guldin from the West Indies by Father Gaspar Ruess, whom he had once instructed at Ingolstadt, and from the East Indies by others; and that when these were compared with his own and with those of others made in Europe, no parallax whatever was detected, but the same spots were seen in the same place on the Sun in both. Father Carolus Malapercius [Charles Malapert] also noted this, comparing his own observations with those made at Coimbra by Father Gulielmus Vuely from the year 1620 to 1623, and with those received at Kalisz in Poland. Assuming Tycho's distances, moreover, Scheiner shows that the spots, from the absence of any sensible parallax, are nearer to the Sun than the Sun itself at apogee is to itself placed at its mean distance. And he concludes the chapter by asserting that when the Sun is without any spot, this is so over the whole globe of the Earth; that when a new spot rises, this happens everywhere at the same time and at the same place on the Sun; and that when some spot occupies the centre of the solar disc or the ecliptic, this happens everywhere on Earth at the same time; and that no deviation of any spot from the Sun's disc has ever been noted.

But in Chapter 56 he teaches that the spots are in the very body of the Sun, from the apparent inequality of refraction introduced into the motion of the spots by the observing lenses; [Margin: The spots[42] are shown to be in the Sun itself.] and in Chapter 57 from the faculae, which were shown above to be in the Sun — therefore the spots too, which are moved with equal motion and in the same order; and in Chapter 58 from the slenderness the spots usually show near the Sun's horizon, or limb; and in Chapter 59 from the intervals of two spots, or of one advancing day by day; and in Chapter 60 from the proportional intervals of the times and motions with which the spots are moved when they proceed with a rectilinear course along parallel lines on the Sun's disc; and in Chapter 61 from the quasi-elliptical path of the spots when the course is curvilinear; and in Chapter 62 from the properties of the curvilinear paths, which recur at half-yearly intervals; and in Chapter 63 from the intervals of a single curvilinear course; and in Chapter 64 from the polar small circle which the axis of the spots' rotation describes; and in Chapter 65 from the periodic return of many spots which are not corrupted before 28 days, their return being argued from the same place, time, motion and parallel. Such was the one that in the year 1625, from March 22 at $8\frac{1}{8}^{h}$ in the morning to April 4 at $1\frac{1}{9}^{h}$ in the evening, was in the Sun's southern parallel; and another of the same year, from May 11 to June 18, in the northern parallel; and a third which, in the same year, rose on June 8 but was completed on the 19th, and lasted until July 15, from north to south. [Margin: Examples of returning spots.] And from a fourth spot which, born in the same year on July 12 but full-grown on the 24th, set

[42] printed *Macula*, singular, with the plural verb

astronomically, and, having traversed the hidden hemisphere of the Sun, rose astronomically on August 6 at $7\frac{1}{2}^{h}$ in the morning, and set astronomically on the 19th at $4\frac{1}{3}^{h}$ in the afternoon; and so with the rest. And in Chapter 66 from secondary spots going about the poles and small circles of this motion with a motion proportional to the others. I would add that it is possible that the spots are on the physical surface of the Sun itself and are carried round with the motion of the Sun's rotation; and if this possible case were actually brought into being, we would have no other indications and arguments, or none greater, than those we have now; therefore these arguments are entirely sufficient to conclude that the matter stands so, rather than that the spots are moved by many motions of their own.

XXI. In part 2 of book 2 he explains the theory of the solar phenomenon, especially as it bears on the motion of the spots, and in Chapter 1, reduced to a short summary, he teaches the following. [Margin: From part 2 of book 4.] The regular apparent motion of the spots about the Sun's centre is twofold: one annual, the other almost monthly. Since this motion is rectilinear twice a year, at intervals of six months, namely at the beginning of June and of December, its axis must lie in the apparent circle of the Sun, or horizon. [Margin: Preparation for the theory of this phenomenon.] And since for six months it is curvilinear towards the south and for six towards the north, the curvature on each side gradually swelling up to the maximum and gradually subsiding, in an even proportion of times and curvatures, the said axis must for six months raise its one half above the plane of the solar circle, the other half being depressed by as much. And since the curvature of the spots' motion grows from the beginning of December for three months up to the greatest curvature, and decreases over another three, and the same then happens in the opposite region of the Sun, the axis already mentioned must be carried round annually, and small circles must be described by its poles on the Sun's surface, one towards the south and the other towards the north, one half of each appearing in the hemisphere of the Sun manifest to us, the other lying hidden in the concealed one. Further, he calls the solar ecliptic the common section of the plane of the celestial ecliptic and of the open solar circle, or solar horizon. He says that the poles from which the small circles already mentioned are described about the fixed axis of the Sun lie on the perimeter of the solar circle, or in the solar horizon, a quadrant distant on either side from the solar ecliptic; and that the fixed axis, about which the small circles are described, is the diameter of the Sun that cuts the line of the solar ecliptic orthogonally at the centre of the Sun. [Margin: Position, magnitude and period [?] of the polar small circles.] And although the semidiameter of the polar small circles already mentioned has been found to be sometimes 6 degrees and sometimes 8, of which the Sun's perimeter is 360, yet more frequently and more carefully it has been found to be 7, which he also chooses. The periodic time is annual, and its beginning is most probably taken from the contact by which the lower pole reaches the south-western part of the solar horizon about the end of November and the beginning of

December, so that the root of this motion can be fixed at about the first day of December, at the contact of the small circle with the south-western part of the solar horizon. This annual motion takes place from west to east, and contrary to the monthly motion of the spots, which takes place about this mobile axis in such a way that they tend from the eastern region of the Sun to the western in the part visible to us. Finally, the duration of a rotation of the spots, when it is complete, sometimes scarcely exceeds 25 days, often reaches 27, and sometimes 28. [Margin: Monthly period of the spots.] Chapter 2 follows, in which is the theory of this motion.

Syſtema Generale ac Theorica Motus Macularum Solarium.

The general system and theory of the motion of the solar spots.

Diagram. A large circle, the solar disc, with its centre at E, crossed by the horizontal diameter A–B and by four further chords, R–L and K–S above the diameter and T–N and M–Q below it. At the top stands a small circle about C, cut by the chord G–O, and at the bottom a small circle about D, cut by the chord P–F; straight lines drawn from the arcs of both small circles converge through E. "Boreos." (north) is set above the figure, "Auster." (south) below it, "Oriens." (east) vertically on the left and "Occidens." (west) vertically on the right.

- Boreos. (top): north
- Z (top of the upper small circle)
- l, m, n, o (points on the upper arc of the upper small circle, left to right with Z between m and n)
- G, O (ends of the chord through the upper small circle, on the large circle)
- C (centre of the upper small circle)
- t, r, p, s, q (points within the lower part of the upper small circle)
- R, K, A, T, M (left ends of the chords, top to bottom)
- L, S, B, N, Q (right ends of the chords, top to bottom)
- E (centre of the large circle)
- Oriens. (left margin of the figure): east
- Occidens. (right margin of the figure): west
- c, b [?], e, d, a (points within the upper part of the lower small circle)
- P, F (ends of the chord through the lower small circle, on the large circle)
- D (centre of the lower small circle)
- f, g [?], Y, h, i (points on the lower arc of the lower small circle, left to right)
- Auster. (bottom): south

[Margin: From book 4, part 2, chapter 2.] XXII. In the preceding figure, let the solar horizon BCAD be described from the centre E of the solar globe; it separates the hemisphere of the Sun visible to us from the hid- den one (although the hemisphere is not seen by us as such, because of its immense distance, but as a flat disc); and for convenience let the Sun be imagined to

be in the meridian or the nonagesimal, etc.; and let the four cardinal points in the solar horizon be A, the eastern; B, the western; C, the northern; and D, the southern. Let the line of the solar ecliptic be AEB, and let its fixed axis, parallel to the axis of the celestial ecliptic, be CD, whose northern pole on the Sun's perimeter is C and southern pole D. For because of the Sun's very great distance we can take ADBC as the perimeter of the greatest circle in the Sun, and the line CD as its axis, granted that, strictly, we do not see the greatest circle of the Sun. Now let the small circle GZor be described from the pole C, and the small circle FYPc from the pole D, whose semidiameter CZ, or DY, subtends 7 degrees of the solar perimeter, of which the whole perimeter ACBD is 360. Let the small circle GO be called the Arctic, or Northern, and the small circle PF the Antarctic, or Southern. These small circles are to be thought of not as lying in the same plane as the solar horizon, as this page shows them, but as erected orthogonally to it; and they are to be divided into twelve equal segments, for twelve signs, as it were, and the twelve months of the year. These small circles are described by an annual motion of the poles of that axis about which the monthly motion of the spots takes place; and this axis we shall call the mobile axis.

At the beginning of December, then, let the southern pole of the mobile axis be at the contact F, and the northern at G, so that the mobile axis is FEG. Then let the pole F be moved on the surface of the Sun visible to us, but towards the east, so that when December is over, at the beginning of January, it is at a, and the pole G, by a contrary motion, has reached l, but on the surface of the Sun hidden from us; and let the mobile axis be aEl. At the beginning of February, let the southern pole be at b and the northern at m, and the mobile axis then be bEm. And finally, when the quadrant Fc has been completed, let the southern pole be at c at the beginning of March, and the northern at Z, and the mobile axis be cEZ. And let these poles continue in this way, so that at the beginning of April the southern is at d and the northern at n; at the beginning of May the southern at e and the northern at o; and at the beginning of June let the southern be at the contact P of the solar horizon, setting heliacally for us, or hiding itself behind the back of the Sun, while the northern rises for us at the contact O, about to traverse over six months the semicircle OrG visible to us, just as the southern will traverse the hidden semicircle PYF. So at the beginning of July the southern pole will be at f, and the northern at p; at the beginning of August the southern at g and the northern at q; at the beginning of September the southern at Y and the northern at r; at the beginning of October the southern at h and the northern at s; and at the beginning of November the southern at i and the northern at t. Finally, when the annual revolution has been completed, at the beginning of December the southern pole will again be at the contact F, rising optically for us, and the southern [?] at the contact G, setting optically for us.

[Margin: At the beginning of December.] XXIII. When the southern pole is at the contact F, and the southern [?] at G, the paths of the spots are rectilinear

to sense, but not parallel to the solar ecliptic AEB; rather, the greatest parallel described by the path of the spots is TES (which, however, to avoid confusion, I have not drawn in the figure), whose greatest southern declination from the solar ecliptic, namely the arc TA, and greatest northern declination, BS, are equal to the arc GC, that is, of 7 degrees; and the motion of the spots is from the eastern point T towards S, or at any rate along parallels to the line TES.

[Margin: At the beginning of June.] When, however, the southern pole is at the contact P and the northern at O, the motion of the spots from east to west is rectilinear to sense, but the greatest parallel described by them is KEN, declining towards the north by the arc AK and towards the south by the arc BN, of 7 degrees.

[Margin: At the beginning of March [?].] When the southern pole is in the middle of the visible semicircle, that is, at c, and the northern at Z, the curvature of the spots' paths is greatest, with the convexity swelling towards the north; but the diameter of the greatest parallel described by the spots in their monthly motion coincides with the line AEB of the solar ecliptic and does not decline from it at all; and this station is called the vernal equilibrium. For there, the Sun being, as we have supposed, in the meridian or in the nonagesimal degree of the ecliptic, the ends A and B of the greatest parallel appear equally raised above our horizon.

[Margin: At the beginning of September.] When the southern pole is in the middle of the hidden semicircle, at Y, and the northern in the middle of the visible one, at r, the curvature of the paths is greatest, but with the convexity swelling towards the south; and then too the diameter of the greatest parallel coincides with AEB without any declination, and there is the autumnal equilibrium, the ends A and B being equally raised, etc.

At the remaining times of the year the convexity of the paths behaves as follows. For the greater part of December, and almost the whole of January and February, it swells towards the arc ARC of the solar perimeter, intercepted between the eastern and northern points; for the greater part of March, in April, and for almost the whole of May, they swell towards CLB, intercepted between the northern and western cardinal points of the Sun; but for almost the whole of June, the whole of July and almost the whole of August they swell towards AMD, the arc intercepted between the rising and the southern cardinal points; and finally, for almost the whole of September, the whole of October and almost the whole of November they swell towards BQD, the arc intercepted between the western and southern cardinal points of the solar perimeter.

So you see that by a single annual motion of the solar axis in the order of the signs (if you look at its visible pole), and by a quasi-monthly motion of the spots against the order of the signs, that is, from rising to setting (if you look at their path visible to us), made about that mobile axis, the phenomena of the motions of the spots are saved; and that this annual motion of the solar axis is

posited more safely, and without absurdity, than an annual motion of the Earth. [Margin: A corollary in favour of the Earth's rest.]

XXIV. The Torrid Zone of the Sun, so to speak, or Royal Road, within which the greatest part of the faculae and spots, and of the ordinary ones, proceeds, is contained by the arc MAR on the rising side and the arc QBL on the setting side. Its bounds are parallels of the solar ecliptic, but within it the paths and bends are wonderfully inclined and alternating. The whole breadth of this zone does not exceed 60 degrees, of which 30 are to be understood in the arc AM or BQ, and the remaining 30 in the arc AR or BL, granted that in a small figure we have not represented that quantity. Therefore, since the zones that are, so to speak, frigid, because of the scarcity of faculae, are of 7 degrees, as large as CG and DP, there remain 53 degrees each for the remaining, temperate zones, in which rare and not very conspicuous spots or faculae occur — namely the arcs RG and OL, or MP and FQ.

XXV. This done, Scheiner treats in Chapter 3 of the size of the circle of the Sun visible to us and its difference from the greatest circle of the Sun; in Chapters 4 and 5 of the Sun's apparent diameter and the way of observing it; and in Chapter 6 of the size of the Sun and of the spots, both visual and true, supposing Tycho's distance of the Sun and the size of the Earth's diameter, which he supposes as can be seen in the table below. [Margin: From book 4, part 2.]

According to Tycho and Scheiner

	German miles	Roman miles
Semidiameter of the Earth	860	3440
Semidiameter of the Sun	4602 1619/4000	18411 6/10
Circumference of the Earth	5403 2152/4000	21614 152/1000
Circumference of the Sun	28920 3612/4000	155683 612/1000

With these assumptions, he sets out various classes of spots with their size, beginning from the smallest, which are like a point, and proceeding up to the greatest, which I have reduced to a synopsis in the following table. [Margin: Size of the spots.]

Order of the spots	Proportion of the visual diameter of the spots to the visual diameter of the Sun	Size of the diameter of the spots in Roman miles
Simple: A	1 to 2000	18 4/10
B	10 to 2000	187 2/5
C	As 50 to 2000	964 0
D	100 to 2000	1928 0
E	143 to 2000	2640 0
Composite: F	285 to 2000	4419 0
G	As 333 to 2000	6292 0
H	500 to 2000	9640 0

He gives an example of spot E in 1625 April, and says it was equal to Europe; of spot F, on 1626 May 26, greater than Africa; and of spot G, in the year

1625, March 25, equal to Asia; and finally of spot H he gives an example on 1625 April 19, which he says was nearly equal to the disc of the Earth, or to half its circumference. But since the Sun is about seven times higher for us than for Tycho, and its diameter is to the diameter of the Earth not as 5 ½ to 1 but as about 34 to 1, as we said in Book 3, chapter 11, the spots just mentioned therefore turn out about seven times larger than Scheiner set them. The remaining matters he treats up to the end of the book concern the qualities and substance of the Sun and of the heavens, about which enough has been said elsewhere.

[Margin: Chiaramonti's blunder about the shadows of the solar spots.] XXVI. When I had written this, I came upon Book 9 of Chiaramonti's *De Universo*, in chapter 1 of which he reports the opinions of several people on the spots of the Sun, especially that of Ioannes Iarde, who thinks they are stars and calls them the Bourbon stars [sidera Borbonia]. In chapter 5, however, he contends that they lie far below the Moon. His reason is that if they were adjacent to the Sun, and one of them were so large as to equal the terrestrial globe, its shadow would still be no longer than two semidiameters of the Earth; whereas, if it had to shade a small part of the Sun for us, the apex of its shadow would have to reach the Earth and be very nearly 1105 terrestrial semidiameters long, which is the least distance of the Sun set by Copernicus. But the good old man is mistaken. For an opaque body to cover part of a luminous body for us, it is not necessary that its shadow reach our eye, as is clear from central but annular eclipses of the Sun, which we treated in Book 5, chapter 8, number 4, and chapter 9, problem 7; it is enough that it intercept some rays of the luminous body from us. The privation of these rays, in the air and in our eye, cannot be called a shadow simply, but at most a shadow in a certain respect [secundum quid].

CAPVT XIII. Diſſoluuntur quinque Argumenta pro motu Terræ vel Annuo vel Diurno, ex motu multarum rerum versùs Orientem deſumpta.

CHAPTER XIII. Five Arguments for the motion of the Earth, either Annual or Diurnal, taken from the motion of many things towards the East, are refuted.

[Margin: 1st argument: from the perpetual wind of the Torrid Zone.] I. Some take the first argument from the breeze or wind that blows almost perpetually from the east within the Tropics, which Galileo and Gassendi ascribe to the motion of the Earth towards the east. But this argument remains sufficiently answered by what was said in chapter 7, number 4. Mastrius and Bellutus, however (disputation 4 on the heavens, question 4, number 121), add that if the Earth moved, this perpetual wind would be felt better on land than at sea, inasmuch as the air is enclosed within valleys, mountains and trees.

[Margin: 2nd argument: from the veins of metals.] II. Others draw the second argument from the fibres and veins in the mines of metals, which are turned towards the east; this, they say, seems to come from nowhere else than from the Earth's perpetual motion towards the eastern quarter. But this, if it is true, rather indicates that it comes about from the illumination and heat of the Sun, which begin from the east. Otherwise, if it proceeded from the motion of the Earth, why do rivers, which are more fluid, not bend their course towards the east? So say Mastrius and Bellutus in the place indicated a little earlier. I said "if it is true", because the veins of stones, and of trees, are found to be turned rather towards the poles of the world.

[Margin: 3rd argument: from an iron plate turned towards the poles.] III. Thirdly, some say: let an iron plate be hung in balance by a bronze wire in a small, well-closed room, so that one of its ends points to the east and the other to the west; a little later it will bend so as to point to the Poles. They therefore think this an argument for the motion of the Earth towards the east, when they ought rather to recognise the magnetic force of iron, which turns itself towards the motionless axis of the Earth.

[Margin: 4th argument: from the danger of corruption.] IV. Fourthly, others say that things which are not agitated perpetually or frequently tend little by little towards corruption; therefore, lest the Earth, the nurse of all things, should be corrupted, it had to be agitated perpetually towards the east. They also add a soul to the Earth, as a salt, so that it should not putrefy. But if the talk is of partial corruption at the surface, that cannot be avoided by the motion of the Earth; if of total corruption, there is no danger, since it is not easily alterable, except around the moister parts of its surface.

V. The fifth argument, from the motions of the sea and from its flux and reflux, needs a longer examination; it is therefore to be set out in a separate chapter, the following one, and brought to the balance.

CAPVT XIV. Ad Argumentum pro diurno & annuo Telluris motu ex Maris Aeſtu deriuatum, intelligendum ac diſſoluendum, tractantur accuratè tum hiſtoria Aeſtus Marini, & aliorum Maris motuum, tum Opiniones celebres de Cauſa Aeſtus Maris.

CHAPTER XIV. For understanding and refuting the Argument for the diurnal and annual motion of the Earth derived from the Tide of the Sea, there are treated accurately both the history of the Sea Tide and of the other motions of the Sea, and the celebrated Opinions on the Cause of the Tide of the Sea.

I. Here, surely, if anywhere, Galileo exulted, in Dialogue 4 on the twofold system of the world. For the first page of that dialogue, which in the Italian is 409 but in the Latin 309, begins thus: *After I had examined again and more often by myself the effects and accidents, partly seen by me myself, partly learned from others, which are observed in the motions of water; and had moreover read*

and heard the notable vanities that many have brought forward to give the reason of these accidents, I felt myself not lightly drawn to admit these two conclusions, the necessary presuppositions being made, however. [Margin: Galileo's two conclusions on the tide of the sea.] The conclusions, which he adds at once, are these: *If the terrestrial globe is immobile, then the flux and reflux of the sea cannot happen naturally. On the contrary, if the motions already assigned are conferred on the same globe, it is necessary that the sea be subject to flux and reflux, according to all those things that are observed in it.* A few lines later, however, he admits that he does not claim so much for himself as to be able to give an adequate reason for all the effects that may perhaps be found in seas situated outside the Mediterranean, *but nevertheless to propose a key that may open the door of a road never trodden by others*; and he adds: *And although in other seas remote from us accidents unknown to our Mediterranean may be found, the reason and cause that I shall produce will not for that reason cease to be true, provided it is confirmed by the accidents of our sea and fully satisfies them: for in the end there must be a single, true and primary cause of effects of the same kind.* From this it appears that his reasoning and judgement stumble at once, on the very first threshold. For if the accidents of the sea tide outside the Mediterranean are not of the same nature as the accidents seen in the Mediterranean, but very different, and in some places in a way opposite — and that in seas much vaster than the Mediterranean — how can he affirm with so confident a mind that a cause satisfying the tide of the Mediterranean will also satisfy all the tides of all seas? He does just as if someone who had discovered a cause of quartan fever that satisfied all its properties were to assert that the same cause is the cause of all fevers, although he had not known their accidents beforehand. But let us hear from him, partly in the person of Salviati, partly in that of Sagredo, the history of the sea tide observed in the Mediterranean, so that we may come to know thoroughly the foundation of his opinion.

[Margin: The threefold period of the sea tide.] II. He says, then, that three periods are observed in the fluxes and refluxes of sea water. The first, chief and greatest is diurnal, by which the waters are alternately raised for about 6 hours and lowered for another 6 hours. The second is monthly, which seems not indeed to be produced by the Moon, but to vary the first by alteration, with a notable difference according as the Moon is new, or full, or halved. The third is annual, which seems to depend on the Sun, inasmuch as the Sun makes the diurnal fluxes greater or lesser, and different at the solstices from those that occur at the equinoxes. [Margin: In the diurnal motion, a threefold variety.] In the diurnal tide, moreover, he affirms that three diversities are noticed. In some places the waters swell and subside without progressive motion; in others, without rising and falling, they now advance towards the east, now run back towards the west; in some places, finally, both the rising or swelling and the progressive and regressive course vary, as happens at Venice, where the waters swell as they approach and subside as they recede. They do this at the far end of the length of gulfs that extend from west to east and are bounded by such shores as give the water room to spread itself when, raised, it swells. But if its

course were cut off by mountains or by higher embankments, there it would swell and subside without progressive motion. Further, the waters of the sea run and run back without swelling or change of height in the middle parts of the Mediterranean, as happens most evidently in the Faro of Messina, or Sicilian Strait, between Scylla and Charybdis, where the running waters are very swift because of the narrowness of the channel. But in the more open seas, and around the Balearic islands, Corsica, Sardinia, Elba [Ilua], the African coast of Sicily, Malta, Crete, etc., the changes of height are very small, but the currents of the waters are notable, especially where the sea is confined between two islands, or between some island and the mainland.

[Margin: A cause of the sea tide refuted by Galileo.] III. Having narrated these things first, he refutes two causes of these effects brought forward by some. The first comes from some Peripatetic or other, who, clinging to the text of Aristotle, had said that the deeper waters by the weight of their mass expel the less deep, which, thrust upwards, strive to descend, and that from this continual struggle the flux and reflux arise. For only waters that have a higher surface drive away the lower and humbler ones, whereas deeper waters cannot do this; and then, when the higher have settled on the lower, they soon come to rest and are brought into equilibrium with them. The second cause is the one that not a few refer to the Moon: that it predominates over moist bodies, and entices to itself and raises a heap of waters, which, continually following the Moon, make a swelling in the part to which the Moon is vertical; and that when the Moon has gone below the horizon, that swelling returns after six hours because of the tractive power which the Moon has communicated to the opposite degree of the zodiac; or else that the Moon by its temperate heat rarefies the waters, and that they therefore swell. This one, I say, he rejects on the ground that the Moon passes over the whole Mediterranean every day, and yet the waters are not raised except at its more easterly extremities and near Venice; that a moderate heat does not suffice to raise water by force of rarefaction, as anyone can test in water that is tepid and not yet boiling; and that no reason for the disparity can be given from it, why the Moon should rarefy the waters at Venice and not rarefy them at Ancona, Naples and Genoa. So he counts these and similar causes among poetic fictions.

And when Simplicio in that dialogue had said that he would rather refer this effect to a miracle, as being supernatural, since Aristotle too, at the beginning of the *Mechanical Questions*, seems to ascribe to a miracle the cause of certain things whose causes are hidden, or to count them among marvels, Salviati replies that if a miracle is to be introduced for the sea tide, it is rather the motion of the Earth that should be introduced, made by miracle and supernaturally; upon its motion the tide of the sea would then follow naturally and by a simpler way, and there would be no need of more miracles. [Margin: Another cause of the tide rejected [?].] For with the Earth motionless no reason can be given why the water at Venice swells by ten palms and more within 5 or 6 hours, with no change of weight, of density, of coldness or of saltiness (lest anyone

have recourse to rarefaction), but by a manifest inflow onto the shores, and yet is not raised perceptibly at Ancona, at Dyrrachium or at Corfu [Corcyra]. For if anyone has recourse to the waters of the Ocean entering through the Strait of Gibraltar [Gaditanum fretum], that is, a channel no more than 8 miles wide: if that water had to reach the farthest shores of the Mediterranean in six hours, and cover two or three thousand miles, it would certainly travel more than 400 miles in one hour, which is an incredible velocity; nor could ships in that strait, or near it, make headway against it, which they nevertheless do. Since, then, this cannot be explained if the Earth, as a vessel containing the seas, rests motionless, it must be investigated whether the causes of these vicissitudes can be explained by the motion of this vessel. This he does

[Margin: The likeness of the tide, taken from the water of a moved vessel.] by considering what would happen to a vessel or ship full of water if the vessel or ship were moved with a gentle progressive course towards one side, but with unequal velocity. For the water, being fluid and not firmly cohering to the vessel, would, while the vessel was retarded, keep part of the impetus it had conceived, run forward, and be raised at the vessel's leading end. On the contrary, if the vessel's motion were quickened, the water, keeping part of its slowness and remaining somewhat behind, would, before it had wholly conceived the new impetus, recede to the following part of the vessel and be raised there; in the middle of the vessel, however, hardly any swelling of the water would appear, but rather a more notable current than at the extreme edges. Now effects of this kind may be seen in the tides of the Mediterranean. It is therefore consistent that its vessel, that is, the Earth, is moved by such motions as now retard it, now quicken it; and that the Earth, further, because of the mixture of the annual and the diurnal motion, is moved now more slowly, now more swiftly, he teaches by the following diagram.

[Margin: The motion of the Earth made unequal by the diurnal and the annual.] IV. From A as centre let the great or annual orb BCDE be described; and on its periphery, taking any point, say B, let the terrestrial globe FGHK be described, which is to be understood as moved, with the motion of the centre B, towards the east, C, so that in one solar year it runs through the whole periphery of the great orb.

Diagram. In the right column: a large circle with centre A, the great or annual orb, with C at the left, D at the foot and E at the right; at its top, on the circumference, the point B. About B are drawn a small circle, the terrestrial globe, and a middle-sized circle passing through O at its top and L at its foot, with a small crescent figure drawn on it at O and another at L. A long arc runs from P at the left, through O, to a point at the right. M and N stand inside the large circle on either side of A. No caption.

- O (top of the middle circle, beside a crescent figure)
- H (top of the small circle)
- K (left of the small circle)
- B (centre of the small circle, on the great circle)

- G (right of the small circle)
- F (foot of the small circle)
- L (foot of the middle circle, beside a crescent figure)
- P (left end of the long arc)
- [?] (right end of the long arc: a swash sort, Q or an ampersand)
- M (inside the great circle, left of A)
- A (centre of the great circle)
- N (inside the great circle, right of A)
- C (left on the great circle)
- E (right on the great circle)
- D (foot of the great circle)

Further, let the same globe be understood to revolve daily about its centre B, likewise towards the east, from H through K into F and G, until it has completed its diurnal revolution when 24 hours have passed. For from this it comes about that any part of the circumference of this globe is moved, though at different times, by contrary motions: while the parts near H are moved towards the left side, K, the parts placed at F are moved towards G, the right quarter; and while the parts go up from G into H, the parts from K go down into F. With this contrariety of motions posited, therefore, when the motion of the diurnal turning is joined with the annual motion of the centre B, there must result at the surface of the Earth a motion now quite accelerated, now retarded by just as much. For the parts around H will be moved most swiftly, since the annual and the diurnal motion conspire in the same direction, that is, towards the left, the one tending into C, the other into K: *Therefore in such a case the diurnal motion increases and accelerates the annual motion* (these are Galileo's own words). By contrast, in the part F the motion is retarded, because although by the force of the annual motion it is carried towards the left, yet by the force of the diurnal motion it is carried towards the right: *Therefore the diurnal motion will subtract from the annual motion.* Around the points G and K, however, the annual motion is nearly simple and uniform, since the diurnal adds nothing or very little to the annual motion, or subtracts nothing or very little from it, inasmuch as there it is carried neither to the left nor to the right, neither up nor down. This inequality of the motions of the Earth, then, is the chief and primary cause of the sea tide, especially of the tide made lengthwise, towards east and west.

[Margin: 1st accident.] V. After this Galileo considers five notable accidents of the sea tide. The first is that water raised at the end of some vessel by the force of acceleration or retardation does not stay in that elevation, but not only brings itself back to equilibrium by flowing back, but also, by its own weight, with the impetus so conceived, springs back to the opposite side, raising itself towards the other edge of the vessel, just as the bob of a pendulum after its descent rises through the opposite arc. [Margin: 2nd accident.] The second is that the reciprocations of the rising water already mentioned, from one side to the other, are more frequent in shorter vessels and rarer in longer ones, just

as the vibrations of a pendulum hung from a shorter cord are more frequent than those of one hung from a longer. [Margin: 3rd accident.] The third is that, among waters enclosed in channels of equal length, those that are deeper complete their reciprocations in shorter times, while those that are less deep do so less frequently. [Margin: 4th accident.] The fourth is that waters enclosed in a vessel, or in the channels of the Earth, are alternately raised and lowered around the ends of the vessel without progressive motion, unless perhaps in swelling they overflow beyond the embankments; but the parts placed in the middle run out forwards and backwards without perceptible swelling. [Margin: 5th accident.] The fifth is that in small vessels the acceleration and retardation are shared in the same way by the whole vessel and by every part of it; but not so in the immense channels of the sea. For when one end is retarded because of the mixture of the diurnal and annual motion of the Earth, the other end is still carried along by a very swift motion: as in the preceding figure, when the parts of the sea at H are moved swiftly, the parts at G are nevertheless moved less swiftly, and the parts at F most slowly, if the stretch of sea is so long as to equal the quadrant HG or the semicircle FGH.

[Margin: Cause of the 1st effect of the sea tide.] VI. When these things have been well considered, it is not difficult to give the reason of several effects that are conspicuous in the tide of the sea. First, in lakes, pools and small seas no perceptible tides appear, because of the frequency of the reciprocating vibrations, before they can complete their effect from the retardation and acceleration of the Earth, which take place alternately every 12 hours. For before that, the waters, somewhat raised at the ends because of the narrowness of the vessel, slip back by their own weight to equilibrium within one, two or three hours, and so a notable tide is prevented. [Margin: Cause of the 2nd effect.] Secondly, although the period of velocity takes 12 hours through the semicircle GHK, and the period of slowness 12 hours through the semicircle HFG, yet from the different length and depth of the seas it comes about that those alternations take place every 6 hours, or at least that these are observed more frequently in our seas, though not in all. For in the Hellespont, in the Aegean, and in the Euripus at Euboea the periods are quite short and very different from one another. [Margin: Cause of the 3rd effect.] Thirdly, therefore, in seas and gulfs that are long indeed, but extended in length not towards east and west but towards the poles, as the Red Sea nearly is, almost no tide appears, because the motion of the Earth is lengthwise, not towards the poles of the world, and so the impulses of the waters strike the meridians, not the parallels of the equator. [Margin: Cause of the 4th effect.] Fourthly, from what we experience in a vessel full of water and agitated towards one side, it is easily established why at the extremities of the Mediterranean the water is raised notably, so that at Venice it rises to 5 or 6 feet, whereas elsewhere the elevation is very small, so much so that around Corsica and Sardinia, and in the estuaries of Rome and of the port of Livorno [Ligurni portus], it does not exceed half a foot. [Margin: Cause of the 5th effect.] Fifthly, therefore, the same quantity of water, although

otherwise it runs gently, must nevertheless run with great impetus through the narrower channel if the whole of it has to be poured through a narrow channel out of a wider one, as happens in the Sicilian Strait, in the Strait of Magellan, and in the sea enclosed between Africa and the island of St Lawrence. Sixthly, however, these vicissitudes can be varied not a little both by the blowing of winds and by rivers breaking into the sea, especially as regards the course of the waters, which are carried in the direction in which the rivers drive them. Thus in the Thracian Bosporus the water always runs from the Euxine into the Propontis, and in the Sicilian Strait it runs from the Ionian into the Tyrrhenian, more swiftly, however, in the Sicilian, because it extends lengthwise.

VII. Thus far Galileo on the cause of the diurnal period of the sea tide. [Margin: Cause of the monthly variation of the sea tide.] After this, having interposed a few things on the perpetual breeze within the Tropics, on the easier navigation towards the west, and on the falsity of the motion of fire from the concave of the Moon, he passes on to investigating the cause of the monthly variation, and affirms, on page 333 of the Latin, that if the annual motion of the Earth were not altered, the monthly period of the sea tide would cease. He teaches, further, that the cause of this monthly alteration is that in the annual orb not the Earth alone is carried round, but the whole lunar system LO. When the Moon is at new moon, at L, and is near the Sun, A, or the centre of the great orb, the great orb with respect to it is the arc MLN etc., describable from A as centre; but when it is at full moon, at O, the great orb with respect to the Moon is POQ etc., any arc of which is greater than any similar arc, that is, an arc of as many degrees, of the smaller circle MLN etc. Now it is certain that, other things remaining equal, the same mobile moved by the same power is moved in a shorter time through similar arcs of a smaller circle than through those of a greater. We see this not only in celestial motions but also in terrestrial ones: for from this it comes about that the vibrations of a shorter pendulum, nearer the centre, are completed in a shorter time than those of a longer pendulum, because they traverse arcs of a smaller circle. From this likewise it comes about that the iron rod which the makers of horizontal clocks place parallel to the horizon and free to swing to the sides, to regulate the clock's time, makes the hours longer if the leaden weights hung at the heads of the rod are hung far from the rod's centre, but quickens them and makes them shorter if the weights are placed nearer the centre, because in the one case they must traverse arcs of a smaller circle, in the other of a greater. Likewise, therefore, the Moon at new moon must traverse in the annual orb similar arcs in the smaller circle MLN, and hence in a shorter time; but at full moons arcs of the greater circle POQ, and in a longer time. That force, then, which moves towards the east not the Earth FGHK alone but the whole lunar system OL, must, because of the Moon, share those monthly varieties with the terrestrial globe, make the annual motion non-uniform, and pour that variety back into the tide of the sea, which is founded on the annual motion of the Earth together with the diurnal. That astronomers have not observed these monthly variations in the annual

motion of the Earth, or, as others will have it, of the Sun, is no wonder, since many other subtleties remain up to now unobserved by astronomers, or only roughly noticed.

[Margin: Cause of the annual variation in the tide of the sea.] VIII. There remained the cause of the annual variation in the tide of the sea to be adduced, which Galileo begins to set out from page 340 of the Latin, 451 of the Italian, having first said, however, that it is rather difficult to understand and requires a great abstraction of mind. He says, then, that the inequality of the additions and subtractions which the diurnal turning of the Earth communicates to the annual motion depends on the inclination of the axis of the diurnal motion to the plane of the great orb, or ecliptic; because of this inclination the Earth's equator cuts the ecliptic, always keeping the same angle of inclination. He says that the addition is as great as the whole diameter of the equator when the centre of the Earth is at the solstitial points, but that outside these it is smaller and smaller, according as the centre of the Earth is less and less distant from the equinoctial points, where those additions become least. But to make the matter clearer: in the following figure let the great orb AIP be drawn, at whose circumference's point A let there be one of the solstitial points, where the centre of the Earth CFBG is. Let its axis CAB be inclined to the plane of the ecliptic, or great orb, and fall in the plane of the solstitial colure, which colure passes through the axis both of the equator and of the ecliptic, since the diameter AP is the common section of the solstitial colure and of the plane of the ecliptic.

Diagram. In the right column: a large ellipse, the great orb, with A at its left end and P at its right end, joined by the line AP; I is its lowest point. At A a small globe figure: an inclined axis from C (lower left) through A to B (upper right), a vertical line through A, and an inclined ellipse, with G and D above, E, M and F below. At I a second globe figure built the same way, with G, D and B above, H and S at the left, L at the right, and C, E and F below. No caption.

- G (upper left of the globe at A)
- D (above the globe at A)
- B (upper right of the globe at A)
- A (left end of the great orb, centre of the first globe)
- P (right end of the great orb)
- C (lower left of the globe at A)
- E (below the globe at A)
- M (below the globe at A, right of E)
- F (lower right of the globe at A)
- G (upper left of the globe at I)
- D (above the globe at I)
- B (upper right of the globe at I)
- I (lowest point of the great orb, centre of the second globe)
- V (a small capital just right of I, on the line to L)
- L (right of the globe at I)
- H (far left of the globe at I)

- S (left of the globe at I)
- C (lower left of the globe at I)
- E (below the globe at I)
- F (lower right of the globe at I)

To avoid confusion, however, let only the equinoctial circle DGEF be drawn, whose common section with the plane of the great orb is the line DE, so that the half DFE of the equinoctial itself remains inclined below the plane of the great orb, and the other half, DGE, is raised above it. Now let the daily revolution of this equinoctial take place in the order of the points DGEF, and let the motion of the centre be from A towards I. [Margin: Variation at the solstices.] While the centre of the terrestrial globe is at A, the axis CAB, erected on the diameter DE of the equator, falls in the solstitial colure, and the common section of this colure and the great orb is AP. It follows that the line AP is perpendicular to the line DE, since the colure is erected on the great orb; and consequently the line DE touches the great orb at the point A. In this position, therefore, the motion of the centre along the arc AM, which by virtue of the annual motion amounts to about one degree a day, behaves just as if it were made along the tangent DAE. And since the point D, carried by the daily rotation through G to E, adds to the motion of the centre, as if moving along the line DE, as much as the whole diameter DE, and conversely subtracts just as much while it moves through the other, lower semicircle EFD, the result is that in this place the additions and subtractions are measured by the whole diameter DE.

[Margin: Variation at the equinoxes.] IX. Now let the centre of the terrestrial globe be moved to I, one of the equinoctial points, and let the equinoctial there be GEFD, with its common section with the great orb DE, and the axis CIB, with the same inclination. But the line touching the great orb at the point I is no longer DE: it is another line that cuts DE at right angles, namely the line HIL, along which the motion of the centre I, advancing through the circumference of the great orb, is to be understood as laid down. With this posited, the diameter DE no longer measures the additions and subtractions that the daily motion brings to the annual motion, since DE does not extend along the line of the annual motion HIL; on the contrary, it cuts it orthogonally. The end-points D, E therefore neither advance nor subtract anything. The additions and subtractions must instead be sought from the diameter that falls in the plane erected on the great orb and cuts that plane along the line HIL; this diameter will be the line GF. The additive motion, so to speak, will be the one made from the point G through the semicircle GEF, and the ablative motion the one made through the semicircle FDG. Further, since this diameter GF does not lie in the line HIL of the annual motion but cuts it at the point I, with the end-point G staying raised above the plane of the great orb and F depressed below it, it does not determine the additions and subtractions by its whole length. Their quantity is to be taken instead from the parts of the line HL intercepted between the perpendiculars raised upon it from the end-points G, F; let these be understood to be GS, FV. The measure of the additions is thus

the line SV, smaller than GF or DE, which was the measure of the additions at the solstices. And from this, finally, comes that third variety of the annual period which appears in the tide of the sea, when one compares the tides that occur at the solstices and at the equinoxes.

[Margin: Galileo's conclusion.] X. Galileo therefore concludes, on p. 342 of the Latin version, that the three fixed and perpetual causes of the tide of the sea are these: the inequality of the daily motion communicated to the annual motion; that inequality varied monthly by the annual motion, by which the whole lunar system is carried faster at new moons and slower at full moons; and finally that inequality varied annually, at the solstices and equinoxes, by the inclination of the axis of the daily motion to the plane of the great orb. The remaining causes are accidental and without rule, partly unobserved and partly unobservable: namely the blowing of the winds, and the depths of the seas and their various lengths, positions and inclinations. He wonders, moreover, that Kepler, to whom those three motions of the Earth were known, nevertheless referred the tide of the sea to the predominance of the Moon over water and to other occult properties. And on p. 344 of the Latin, but p. 456 of the Italian, he holds that this argument, drawn from the tide of the sea, is one of the chief arguments for the motion of the Earth, saying: *"From the conversations of these four days, then, we have notable testimonies in favour of the Copernican system, of which these three seem quite conclusive: the first taken from the stations, retrogradations, and approaches to and recessions from the Earth of the planets; the second from the revolution of the Sun upon itself and from what is observed in its spots; and the third from the flux and reflux of the sea."* [Margin: Gassendi's vote for Galileo.] Pierre Gassendi subscribed to this so far that, in Letter 2 of *De motu impresso a motore translato*, from p. 149 to 155, he reduced Galileo's reasons to an epitome with the example of a small boat full of water, and after the argument from the solar spots, which he likewise thought demonstrative of the Earth's motion, he said: *"Thus Galileo demonstrates; to him is owed, moreover, that from the motions he assigned to the Earth he has explained the tide of the sea in such a way that he seems at last to have found its genuine cause."* [Margin: Authors who attack Galileo.] But the opposite view was held by Chiaramonti, in his Italian defence of the *Antitycho*, part 4, chapters 24, 25, 26, 27 and 28, where he refutes Galileo; by Father Cabeo, on Book 2 of the *Meteorologica*, text 6, from question 7 to 10; and by Father Georgius Furnerius [Georges Fournier] of the Society of Jesus, in Book 9 of the *Hydrographia*, from chapter 14 to 20. These two Fathers refute Galileo's invention far more fully and solidly. But neither their arguments nor ours against Galileo can be properly understood unless a history of the tide of the sea is set out first, and a more accurate one than was given in Book 2, chapter 15, where we were instructing the beginner and there was no occasion to descend so deeply into this controversy.

Hiſtoria Motuum Maris ex diuerſis Scriptoribus Collecta.

A History of the Motions of the Sea, Collected from Various Writers.

XI. Besides those who have described the Indian voyages for us, this history is touched on above all by not a few authors named by us in Book 2, chapter 15, Scholium 1. To these must be added Bartholomaeus Crescentius [Bartolomeo Crescenzio], Book 3 of the *Nautica Mediterranea*, from chapter 2 to 4; Bartholomaeus Mastrius, disputation 4 of *De caelo et meteoris*, question 4, from number 148; Hieronymus Trimarchus, Book 2 of the *Meteora*, disputation 1, from sections 6 and 7; Federicus Delphinus [Federico Delfino], in his opuscule *De maris aestu*; Albert the Great, *De proprietatibus elementorum*, treatise 2, chapter 6; Franciscus Resta [Francesco Resta], Book 3 of *De meteoris aqueis*, in the treatise on the sea, from chapter 13 to 16; Georges Fournier, Book 9 of the *Hydrographia*; Lucas Aurigarius [Lucas Janszoon Waghenaer] of Holland, in the *Thesaurus marinus*; and Claudius Duretus [Claude Duret]. Most of these grant the sea three ordinary motions: one in longitude, another in latitude, a third in altitude. The extraordinary motions produced by the winds we do not consider here.

Primus Maris motus à Septentrione verſus Auſtrum.

The First Motion of the Sea, from North towards South.

XII. The motion of the sea from north towards south was recognized long ago, together with Aristotle (*Meteorologica* 2, chapter 1, text 6), by Alexander of Aphrodisias, St Thomas [Aquinas], Vicomercatus [Francesco Vimercati], Nyphus and most of the interpreters at that place, and also by Albert the Great (treatise 3 of the *Meteora*, chapter 6). For the Maeotic marsh [Sea of Azov] flows into the Euxine Sea [Black Sea] through the Cimmerian Bosporus, the Pontus into the Propontis, the Propontis into the Aegean through the Thracian Bosporus, and the Aegean into the Mediterranean. [Margin: 1. Cause of this motion.] Aristotle gives a twofold cause of this motion. One is the multitude and size of the rivers bursting into the Maeotis and the Euxine, such as the Tanais, the Danube and the Borysthenes, compared with the narrowness and slight depth of the Maeotis and the Euxine, which cannot contain so great a mass of water within their beds but are forced to discharge it at once into wider and deeper seas. For the Maeotic marsh, if we believe the geographers, has scarcely six or seven ells of depth; and Aristotle adds that the Euxine is deeper than the Maeotis, the Aegean sea deeper than the Euxine, and the Sicilian deeper than the Aegean, while the Sardinian and Tyrrhenian are the deepest of the whole Mediterranean. From the same abundance of waters bursting into the Euxine, Strabo (Book 1 of the *Geography*) reports that the Pontus forced itself a way into the Propontis, which it did not have from the beginning, and by continual battering at the Strait of Hercules opened itself an entrance into the Mediterranean. The other cause the Philosopher refers to the height of the land, which is more elevated around the Arctic pole; from this, he says, it follows that

a very great force of waters runs down from the Arctic pole towards the south. As for the Caspian Sea, which does not visibly run down into the Euxine or any other sea, although great rivers discharge into it and it is not very large, the reason is that it does not communicate with the Euxine through any strait or channel. It is therefore forced, as not a few geographers hold, to send its waters through underground passages to the Euxine, and from there to the Mediterranean. [Margin: 1. Confirmation of this motion.] This motion from north to south is further confirmed, first, by the easier and faster navigation from the north to the south: for, as Fromondus [Libert Froidmont] asserts, one sails more quickly and readily in the Atlantic from Denmark and Hollan- d into Spain than from Spain into Holland or Denmark. Our Fournier, too, in Book 9, chapter 22 of the *Hydrographia*, affirms that ships setting out from the Azores towards the equator complete their voyage much more quickly than those that try to return to the Azores from Brazil or from Havana, which are southern places. For these, so as to be less hindered in their oblique course by the waters running towards the south, must coast the shores of America between Florida and the island of Bahama and Virginia, and cover a route ten times longer than the one they had made from the Azores to Brazil. This greater speed is seen in its own way also in navigation from the Euxine to the Aegean, and from the Aegean into the rest of the Mediterranean, even when the winds are still; so that Franciscus Vallesius [Francisco Vallés], in chapter 50 of the *Sacra philosophia*, was wrong to refer it to the north winds. [Margin: Vallés's error about the cause of this motion.] Fournier adds, in Book 9, chapter 31, that in the year 1630 a ship which had sailed from Dieppe and had reached, in February, the latitude of 2° near the equinoctial, after running for 24 hours towards the Libycus [the south-west], although it reckoned it had moved further south, was nevertheless still at 2°, where it had been before, because of the currents towards the Graecus [the north-east]. [Margin: 2. Confirmation.] Secondly, it is confirmed most evidently by the masses of ice which, on the testimony of Fournier at the place cited above, roll down from the north towards the south, as those have found who have sailed across the Atlantic to North America, or from there to Norway. For those going towards Bergen in Norway along Vaëgas or Nieulandia must always steer their course beyond Hunem, unless they want to perish from the ice rushing down from the north. And in the year 1635 a French fleet sailing towards Canada came upon some huge masses of ice like bells, one of them so vast that they could scarcely get clear of it over a space of 40 leagues. Nor does anyone ever sail to Canada without coming upon such floating islands of ice from time to time, rolling down from the north. Since, therefore, such masses of ice always rush from the northern region towards the equator, it is manifest that the sea runs perpetually from there towards the south. [Margin: 3. Confirmation.] Thirdly, it is confirmed by those who have made the voyage to the Moluccas or the Philippine islands: they have experienced an incredible speed of the sea, now from north towards south for 12 hours, now from south towards north for another 12, as Fournier relates at the same place and in chapter

31. Fromondus also notes, from the *Enchiridion* of Bartholinus the Dane, Book 4, chapter 8, that the Baltic Sea not only flows out from the north but also flows back into the north; Bartholinus attributes this to rivers flowing on the one side from the north and on the other into the north, and driving the Baltic with different motions. Many geographers too, especially Mercator Plantinus, Maginus and Bercius, relate that under the Arctic pole there is an immense whirlpool into which the sea is carried very rapidly through four Euripi; how this could have been known, however, Pifferus wonders, on chapter 3 of the *Sphere*. [Margin: The flux of the sea is to be distinguished from this motion.] This motion, however, does not properly include the well-known flux and reflux that runs from the Gothic sea onto the shores of France, and back again from the shores of France towards the Gothic sea; for this is the tide of the sea, reciprocating to and fro every day. It is also seen daily at Spitsbergen, at an elevation of 24°, from north to south and back again from south to north. Further, the cause of the sea's course from north to south in the Gothic sea and the Atlantic, or, at the Moluccas and Philippines, now to the north and now to the south, cannot be referred either to rivers or to the height of mountains from which waters slide down into the sea. In that tract there are no such rivers flowing towards the south, nor is that part of the land higher than the Mountains of the Moon or than America; on the contrary, the Holland and Zeeland sea appears higher than many islands, and the Rhine and many other rivers flow from the Alps towards the north. [Margin: Cause of this motion.] It seems rather to our Fournier, in Book 9, chapter 22 of the *Hydrographia*, that the cause should be referred to the Sun, which continually diminishes the waters within the tropics by its heat and its attraction of vapours. The result is that, as the waters at the surface fail, the waters run by their own weight, on one side from the north and on the other from the south, towards the equator, to level out their surface. This is especially so if it is true, as the same author affirms at that place, that when the Sun is in Capricorn the waters within the tropics cross the equator and rush towards the Tropic of Capricorn, and conversely, with the Sun placed in Cancer, the waters rush from the Tropic of Capricorn towards the Tropic of Cancer. Franciscus Resta is of the same opinion, in Book 3 of the *Meteorologia*, treatise 1, *De mari*, chapter 16, affirming that the Sun's action makes the waters flow now towards one tropic, now towards the other. Nor does he think contemptible what Aristotle had said on another occasion (section 23, problem 20): namely, that salt waters are more stable because of a certain viscosity like oil, whereas fresh waters flow more easily; and the waters near the poles, it is agreed, are less salt, but they could not flow towards the salt waters enclosed within the tropics unless these, by their own depression, gave way to them, leaving a place to be levelled up by the polar waters. Mastrius too, in disputation 4 of *De caelo ac meteoris*, question 4, number 148, thinks that the waters of the sea flow from the south and from the north towards the equator, because, through the excess of heat, much of the water contained in the torrid zone is turned into air, while, on the contrary, near the poles a great

quantity of water rains down into the sea from snows and mists. Bartolomeo Crescenzio, however, in Book 3 of the *Nautica Mediterranea*, chapter 2, ascribes this motion to the action of the Sun in such a way that, while he admits that the water flows from the poles to the torrid zone, he does not admit that the waters within the torrid zone become lower because of vapours consumed. Rather, because waters are drawn up by the Sun and turned first into vapours and then into air, the remaining waters of the seas rush by force of continuity to fill the place of those that were under the torrid zone. Finally, our Cabeo too, on Book 2 of the *Meteorologica*, text 6, question 2, approves the same cause: namely, that there is great consumption of water in the hotter places about the equator and a great abundance of rains and snows about the poles, and that therefore, to preserve the equilibrium of the sea, the waters flow together from both poles towards the equator. But he adds that, just as in very cold weather the colder the surrounding air, the more copious the water that distils through an alembic, so in the polar parts, where the surface of the earth is colder, the vapours rising from the bowels of the earth into the hollows of the polar mountains condense more easily into water and distil into more copious water; and therefore larger rivers or more copious springs of water burst forth from there. [Margin: Are rivers more numerous and larger from the poles, or under the equator?] But Fournier and Crescenzio teach the opposite: namely, that more and larger rivers spring up under the equator, such as the Nile, the Manicongus, the Cuana, the Zaire, the Coanza, the Niger and others in Africa; and in America the Maragnon, the Aureliana, the Silver River [Río de la Plata], the river of St Dominic, the river of St John, and many other huge rivers, with which the rivers that roll down from the northern mountains into the sea can in no way be compared. They think the cause is that the ground under the torrid zone is filled with more and larger pores, because of the exhalations and vapours perpetually drawn out by the Sun, and that more waters rush from underground reservoirs of water to fill these pores. But this is not the place to debate the matter.

Secundus Maris Motus ab Oriente in Occidentem.

The Second Motion of the Sea, from East to West.

XIII. This motion in the sea is no less evident than the preceding one. For it is established that one sails much more quickly, even when the wind drops or drives the sails with an even force, from Palestine to Spain than from Spain to Palestine, and from England to Ireland than from Ireland to England. One also sails more quickly from Spain to the West Indies, so that one reaches Mexico or the islands on this side of it in about one month, or at most two months; whereas one cannot sail back from there in turn except in four, five or even six months, and to escape the waters running towards the west one must catch stronger winds blowing towards the east, and therefore an oblique course towards the north must be set. And the Portuguese too, when they have rounded the

Cape of Good Hope and make for the East Indies, reach Goa or Malacca much more slowly, even with favourable winds, than when sailing back from there westward. Many ship-masters testify to this, and our Father Antonius Magallianus, a Portuguese, confirmed it in the year 1633, when he was appointed Procurator of the Province of Goa to the General Congregation. For the sea runs so violently towards the Cape of Good Hope, especially between Ethiopia and the island of St Lawrence [Madagascar], that the danger of shipwreck there is far greater than in the Sicilian Strait or in the sandy places of Flanders. And our Fathers returning to Europe from the kingdom of China or from the East Indies have affirmed that at times that eastward course cannot be resisted even with favourable winds, especially under the equator. Hence, from this motion or westward course of the waters, the Vallis Iosaphat at the island of St Lawrence is notorious for shipwrecks, as are, in the Gulf of Mexico, the island called Os Draconis [the Dragon's Mouth] and the waters near Guadeloupe and the harbour of Cartagena and of Santa Marta. This goes so far that ships cannot make headway against it even with the wind helping, and can scarcely cover one mile in one day, or 40 miles in 75 days, the sounding-lead being very often swept away towards the west. So Trimarchus testifies, in Book 2 of the *Meteora*, disputation 1, section 6, from the account of ship-masters who were Spanish knights, when he was in Madrid; and so does Willebrord Snellius [Villebrordus Snellius] in his *Tiphys Batavus*, Book 2, proposition 8, adding that between Brazil and Angola this motion of the sea is carried towards the north-west from April 20 to July 20, and towards the south-west from October 20 to January 20. Adrianus Metius also relates, and Fournier after him in Book 9 of the *Hydrographia*, chapter 23, that a certain ship's captain sailing from Brazil to the island of St Helena, which lies east of Brazil, after sailing for several days with favourable winds on the same sixth parallel of the equator, and reckoning himself very close to that island, found that he was still near the coast of Brazil. Moreover, those who sail from France to Brazil head straight for Guinea, so that, having caught the sea's westward course there, they can sail more successfully; for this course is much more perceptible within the torrid zone than far from it. But in the Pacific Sea this motion is most evident. Those sailing from Acapulco head south to the 10th degree of south latitude and, keeping their course on that parallel, reach the Islands of Thieves [Ladrones] in 85 days, having covered 3000 leagues without any use of their sails; and from there, leaving those islands and climbing to the 13th degree of latitude, they reach with the same good fortune Manila, which is in Luzon, one of the Philippines. From the nautical ephemeris of Thomas Roës [Thomas Roe], an English nobleman who was sent by his king as ambassador to the princes of India in the year 1614, and especially from the diary of Gualterus Peyton [Walter Peyton], it is established that, when the English reached the island of Mohelina [Mohéli] on June 22, the inhabitants of that region showed them a stream that flowed eastward for 15 days and westward for another 15 days; and the English confirmed this by their own trial. That island lies between the Cape of Good Hope and the island of St

Lawrence, or Madagascar. No less marvellous is what the lord de Hayes reports, as cited by Fournier, in his itinerary from France to Constantinople: namely, that in the Danube the water runs down faster in the morning and evening than around midday, and that near Buda and Belgrade this is manifest from the wheels of the mills. [Margin: Cause of this motion.] From this Fournier gathers that the cause of the sea's motion towards the west is the Sun, which perpetually draws up vapours and exhalations, especially within the torrid zone, and does so in its own course towards the west; the waters must consequently run in from the east, so as to preserve the equilibrium of the sea by a continuous course. Granted, Kepler, in the introduction to the *Commentaries on Mars*, attributes this to the magnetic power of the Moon drawing out the waters while it moves westward by the daily motion; and he says this power is so great that, if the Earth did not in turn attract the waters of the sea to itself, all the waters of the sea would be raised up and would flow into the body of the Moon. Fournier thinks this was said gratuitously [?]. Others, with Vicomercatus, attribute it to the daily motion of the heavens, which sweeps air and sea towards the west; Franciscus Resta, in the chapter 16 already named, does not oppose this, nor does Mastrius, cited above. Tyennensis, however, in Book 2 of *De elementis*, attributes it partly to the heat of the Sun raising vapours, partly to an occult and as it were magnetic power, by which it carries the waters of the sea along with it, just as it carries the clouds, to wherever it is itself borne by the daily motion; and Trimarchus, at the place already cited, does not disagree. But Scaliger, in exercise 52, Contarenus [Gasparo Contarini], the Conimbricenses and Aversa [Raffaele Aversa] ascribe this to occult qualities of the heavens, with which Mastrius too tacitly agrees. Further, Cabeo, on Book 2 of the *Meteorologica*, text 6, question 3, on the supposition that there is such a motion, places its cause partly in the perpetual or frequent easterly winds, especially within the torrid zone, and partly in the Sun drying up the waters, etc. [Margin: By whom this motion has been called into doubt.] I said "on the supposition", because he himself has doubts about this motion and rather thinks it false; and Fromondus, in Book 5, chapter 1, article 6, denies it, and says that the whole of that ease of navigation westward comes from the easterly winds blowing continually, especially within the tropics. These winds were recognized and attested by Iosephus Acosta [José de Acosta], in Book 3, chapters 4 and 8, and by the nautical diary of the Dutch for the year 1595. From these sources we learn that a ship set out from Lima in the year 1580 and in February and March made 2700 leagues westward on the same parallel, with the winds in the Pacific Sea perpetually seconding it, and that Alvarus Mandana [Álvaro de Mendaña], setting out from Peru, reached the Solomon Islands in a short time by the same favour. Hence it is (says Fromondus, and Cabeo nearly subscribes) that the Spaniards head straight for the Canaries, so as to fill their sails there with the winds blowing from the east and reach the island of San Domingo by a very short route; but on the return they are forced to leave the torrid zone as far as the 37th or even the 40th degree of elevation, so as to enjoy the west winds,

with which they return to Spain as best they can by a long and oblique course, granted that from the 40th degree the winds are already inconstant, on the testimony of Acosta, Book 3, chapter 7.

[Margin: Confirmation of this motion.] But navigation eastward is very difficult even with the winds equal, and indeed with favourable winds blowing towards the east, as we related above. Add to this, from Scaliger, exercise 52, who learned from ship-masters that from the island of Maidegascar, under the eighth southern parallel, one reaches Moabar in India in 20 days, whereas one does not return from there, even with an equal force of winds, except in three months. Since, I say, these things are so, and very many ship-masters, or those most expert in navigation since Columbus, recognize, besides the winds, also and above all this course of the waters, it must not be said that they have been deceived in a matter of such moment.

Motus Maris ex prædictis duobus ortus.

A Motion of the Sea Arising from the Two Already Mentioned.

XIV. Therefore, from the motion of the sea from the pole, especially the Arctic, towards the equator, and from its motion towards the west, there follows a certain other motion in a circle, by which it seems to return eastward through certain straits and along the shores; for while it strikes against the opposite shores it is forced to flow back. Thus Contarenus, in Book 2 of *De elementis*, Scaliger, in exercise 52, and others have noted that the Mediterranean, striking on the shores of Africa and Spain, since it cannot flow out wholly through the narrows of the Strait of Gibraltar as quickly as would be needed, returns by a winding course towards the shores of Africa as far as the coasts of Asia Minor; by this bend it flows along the shore of Dalmatia towards Venice, and from Venice is carried along the shores of Italy as far as the Sicilian Strait. In the Sicilian Strait, moreover, it is very well known that one part of the waters is carried upward and the other downward at the same time, very rapidly. A reciprocal motion up and down, however, is observed in most Euripi or straits, and in the Sicilian Strait indeed the water moves in a circle twice each day towards opposite parts; but this belongs to the tide, of which more below. Scaliger adds that in the Scythian Ocean the waters run eastward, and in the Atlantic towards the Land of Labrador [Terra Laboratoris]. Remarkable, too, is what Fournier says in Book 9, chapter 6: that the Mediterranean flows out through the Strait of Gibraltar for six hours, but the Ocean comes in as victor for 18 hours. But if anyone wants other notable examples of sea waters running towards different regions of the world, let him consult Fournier, Book 9 of the *Hydrographia*, chapter 31.

De Tertio motu Maris, qui Aeſtus dicitur, ſeu Fluxu ac Refluxu in communi, vbi quædam Admiranda.

On the Third Motion of the Sea, which is called the Tide, or Flux and Reflux, in general; with some remarkable things.

XV. Although the motion of the sea, especially the one we pointed out in number 14, can be called flux and reflux, nevertheless, when this word is used more strictly by ship-masters and the more skilled hydrographers, the name "flux and reflux of the sea" means the motion that is not merely boreal but takes place with a certain alteration, on account of which the sea swells and subsides as if by boiling up and cooling down. For this reason it is also called the tide [aestus] of the sea, and the bays and harbours in which the approach of the swelling sea and the retreat of the subsiding sea are manifest are called estuaries [aestuaria]. Some, however, think that *aestus*, like *aestas* (summer), is named from burnt air, or from the abundance of heat. Now the Phoenicians of old, and afterwards the other ship-masters, observed three variations of this tide: one that occurs twice daily, a second that occurs twice every month, at the new moon and the full moon, and a third that occurs every year, in March and September. We shall discuss these in order. Meanwhile some general points must be set out first.

[Margin: The boiling-up of the sea from the bottom.] First, then, the tide occurs not only near the shores, as Bodinus [Jean Bodin] thought — moved perhaps by Pliny the Elder's statement in Book 2, chapter 97: "But these motions are detected more near the shores than in the open sea" — but also around the middle and in the depths; from there the sea, boiling up, drives sea beasts upward to its surface, as Albert the Great (*De proprietatibus elementorum*, treatise 2, chapter 6), Vallesius (*De sacra philosophia*, chapter 52) and Franciscus Resta (treatise 1, *De mari*, chapter 13) affirm. Nor does Pliny deny this absolutely; he speaks comparatively.

[Margin: Wells and springs that ebb and flow with the sea.] Not only the sea, moreover, but certain springs ebb and flow like seas. Such was the spring at Gades [Cádiz], enclosed in the manner of a well, near the temple of Hercules, which swelled and subsided with the Ocean, but at other times did so at different times, as Pliny reports (Book 2, chapter 97). Ortellius [Abraham Ortelius] also relates that in Connacht in Ireland a spring is found on the summit of a mountain which, following the rule of the nearby sea, swells and subsides twice daily. Pliny adds, in the place cited, that on the bank of the Baetis [Guadalquivir] there was a town whose wells sank as the tide rose and rose as it fell, and were motionless at the times between, and that a single well at Seville had the same nature. Finally Albert the Great (*De proprietatibus elementorum*, treatise 2, chapter 5) reports that in certain cities of Arabia beside the sea, as in the city of Azim and in Albastrach, the fresh waters used to ebb and flow with the sea.

[Margin: Whether men die only when the tide is ebbing.] But remarkable, if true, is what Pliny relates from Aristotle in Book 2, chapter 98, saying: "To these things Aristotle adds that no animal dies except when the tide is ebbing. This has been much observed in the Gallic Ocean, and established only in the case of man." Bodin thinks this false. But Levinus Lemnius [Lieven Lemmens] (*De naturae miraculis*, Book 4, chapter 1), although he does not dare to reject Pliny, nevertheless adds that he has found that some people died at the Ocean's approach, and that in the coastal tract of the Low Countries the fat are in danger when the tide is coming in, the thin when it is going out. Fournier, moreover, affirms (Book 9, chapter 1) that mixed bodies never abound more in humours than when the sea surges and swells, and are never more dried out than when the sea subsides and falls; therefore, since the Moon rules over the humours, this is a sign that the tide of the sea has a great connection with the Moon.

Further, it is agreed that if any shore feels the tide, the tide is greatest where the mouths of great rivers are, and that coasts which stretch out into the sea experience it sooner than those that have receded inland. By contrast, rivers themselves, lakes and pools do not undergo a tide of themselves, just as seas that resemble pools, such as the Caspian, do not, unless it is communicated to them from the sea through their mouths. [Margin: Pliny's general statement on the tide.] Lastly, we should recall Pliny's statement in Book 2, chapter 97: "But all tides cover and flood greater spaces in the Ocean than in the rest of the sea," and so on; "neither lakes nor rivers are moved in the same way."

Hiſtoria Aeſtus Maris accurata.

An Accurate History of the Tide of the Sea.

XVI. The tides of Europe stand as follows. In the Mediterranean the greater part of the shores lacks a perceptible tide. Certainly, just as there is none in the Caspian (although that belongs rather to Asia), so there is none in the Euxine Sea either. [Margin: The tide of the Mediterranean.] Of the Euxine there is Pliny's statement in Book 2, chapter 97: "The Pontus always flows out into the Propontis; the sea never flows back inward into the Pontus." In that place he adds: "On the third day one reaches Utica from Italy, when the tide is running high." For the African shores at Utica, Tunis, Hippo and certain other coasts feel some tide, but the island of Malta a greater one. In the Adriatic gulf, around Ravenna and Aquileia, the tide was once so great, on the testimony of Procopius (Book 1 of the *Gothic War*), that it covered many thousands of paces, and sailors waited for the tide in the morning so as to bring in their goods more quickly; in the evening it usually subsided and flowed back. Now it covers about two miles of the Venetian shore and, boiling up from the bottom, as Contarenus noted, rises 3, 5 or 6 feet; for this reason the city has from time to time to protect itself with barriers and embankments, so as not to be overwhelmed by the tide. But around Corsica and Sardinia, in the estuaries of Rome, and around Elba, Malta and Crete it rises scarcely half a foot. On the coast of Provence, at Marseille, it

rises a whole foot. In the rest of the Tyrrhenian Sea no tide is felt, either on the western coasts of Italy or on the eastern shores of France and Spain; nor is any ascribed to the shores of Greece.

[Margin: Euripi.] A greater tide, or flux and reflux of the waves, is seen in Euripi and straits. Pliny (Book 2, chapter 97) testifies that the Euripus of Tauromenium [Taormina] flows and ebbs more often in a day; and Patritius, in his *Pancosmia*, says that in Liburnia, at the town of Assuerum, there is a very narrow Euripus of 10 paces, where the sea surges more than twenty times a day. [Margin: The Chalcidic Euripus.] But nothing is more memorable than the Chalcidic Euripus between Boeotia and the island of Euboea. There the sea flows and ebbs, not at uncertain times or turns, as Livy held (Decade 3, Book 8), but seven times by day and seven times by night, as Cicero (*De natura deorum*, Book 1), Strabo (Book 1), Pomponius Mela (Book 2, chapter 4) and Pliny (Book 2, chapter 97) affirm. St Basil describes this Euripus elegantly in Homily 6 of the *Hexaemeron*; it sometimes rushes with such force that it seems to be pouring down from the highest mountains. But Gillius [Pierre Gilles], who investigated those places, affirms, as Franciscus Resta relates (treatise 1, *De mari*), on the report of the inhabitants, that this Euripus now ebbs and flows only four times, not seven, and that sometimes it does not keep even these turns. Scaliger (exercise 52) refers the cause to waters shut in by rocks lying beneath, which are poured back in alternation.

[Margin: Did Aristotle throw himself into the Euripus?] Some, moreover, report — from Saints Justin and Nazianzen [Gregory of Nazianzus], and from Procopius, Caelius, Vimercatus (commentary 4), Maginus in his description of Euboea, and others — that Aristotle, despairing of grasping the cause of this Euripus, threw himself headlong into it, saying: "Since I do not grasp you, Euripus, you grasp Aristotle." But Laertius says nothing of the kind about Aristotle in his life of him.

[Margin: The tide of the Sicilian Strait.] Before we leave the Mediterranean, however, we must consider the tide of the Sicilian, or Messina, Strait. There, although the water at Scylla and Charybdis rises only a little more than one palm, it nevertheless flows and ebbs up and down very rapidly, so much so that Aristotle counted it among the wonders of the world. Bartholomaeus Crescentius relates (*Nautica Mediterranea*, Book 3) that on 1594 August 3, as he was entering this strait near Scylla and Charybdis, the waters drove on his stern; but when he reached the middle of the channel, another current of water rushed in from Reggio, which, meeting the first, produced a surge of water as if boiling, with swelling and eddies, just as a cauldron full of water usually boils when a fire is set beneath it. This swelling of the tide lasted for a quarter of an hour, until the water rolling out from Reggio overcame the other, which had come from Scyllaeum, or from the tower of the Pharos of Messina. He adds further that certain knights of Messina assured him that this meeting of the waters, and the tide, occurs every six hours, which they attributed to waters shut up in caves and poured back out of them; but Crescentius attributes it

to the Moon, whose 17th day it then was, and it was the 15th Italian hour. In the year 1595, too, when the same Crescentius wanted to leave the mouth of the strait with galleys, he experienced no small fear from that struggle of the waters: the water running from Reggio towards the Pharos drove the ships so that one passed the next very swiftly, but when they came nearer the shore, the other water, meeting them from the opposite side, drove them back — certainly because of the circular motion of the waters. I have often heard similar things from Fathers of our Society who sailed to Sicily to preach or to govern.

[Margin: Is there any tide in the Baltic?] Outside the Mediterranean, the European shores of the Scythian and Baltic Seas have no perceptible tide, on the testimony of Bartholinus the Dane. Cardano, however (*De rerum varietate*, Book 1, chapter 4), reports that beyond Sweden there is a promontory called Nasus, so named from its likeness to a nose, beneath which is a whirlpool that boils every six hours with so rapid a tide that, as it flows back, it swallows ships; Olaus Magnus affirms this too. [Margin: The tide of Norway, Denmark, England, Holland, Flanders.] The remaining shores of Norway, especially the western ones, and also the English, Irish, Danish, Dutch and Flemish shores, undergo huge tides, so much so that in Britain the shores are laid bare for 9 miles, and the Thames feels the tide up to London, as far as 50 or 60 miles, the water rising about 20 cubits. Indeed Pliny says, in Book 2, chapter 97: "Pytheas of Massilia is the authority that the tides swell 80 cubits above Britain." Georgius Bruin [Georg Braun] nearly agrees with him in his *Bristolia*, granting that this swelling rises to 66 feet; and so does Fournier (Book 9, chapter 20), who says he observed himself that in the gulf of the Manche [the English Channel] the tide sometimes rises 70 feet. Also worthy of note is what Bede relates in his life of St Cuthbert, chapter 17, as given in Surius, volume 2: namely, that in the region of Lindisfarne, as the tide of the British Ocean comes in twice daily, an island is formed, and when the shores are twice laid bare again, the place that had been an island, joined to the mainland, appears. [Margin: A remarkable spring.] I said above, from Ortellius, that in Connacht in Ireland there is a mountain on whose summit a spring swells twice daily and subsides twice, following the tide of the nearby sea. They report, too, that terrible tides occur daily on the shores of Iceland. [Margin: The tide of the Low Countries and of France.] In the Low Countries and at Calais the tide rises at new and full moon to 15 or even 18 and 20 feet. The French shores facing the west also experience a very great tide, but two things in them are most worthy of note. The first is that the mouth of the Garonne fills in seven hours and diminishes in five, as Scaliger noted in exercise 52 — although the Lord of Candal, as reported by Fournier (Book 9 of the *Hydrographia*, chapter 1), observed that it fills in 6⅖ equinoctial hours, but empties and subsides in 6 hours. The second is what Franciscus Resta relates (treatise 2, *De mari*, chapter 15), and Fournier (Book 9, chapter 21), and what I seem to have heard myself from Fathers of our Society: namely, that at Mont-Saint-Michel and Saint-Malo the tide rises to 70 feet, and sometimes 90, and recedes over three leagues; and that on the coast of Normandy an island is

formed every day, to which, when the sea has flowed back, one returns across the sand, since it has now become not an island but mainland.

[Margin: The tide of Portugal and Spain.] It is well known that all the rivers of Portugal undergo a tide at their mouths, but above all the Tagus, which therefore flows back towards its source for up to 4 miles. The Baetis, however, runs back as far as 50 miles. On this occasion I repeat Pliny's statement in Book 2, chapter 97: [Margin: Remarkable wells.] "On the bank of the Baetis there is a town whose wells diminish as the tide rises and grow as it recedes, and are motionless at the times between. The same nature belongs to a single well in the town of Hispalis [Seville], the others being ordinary." A little earlier in the same chapter he had said: "At Gades the spring nearest the temple of Hercules, enclosed in the manner of a well, sometimes rises and falls together with the Ocean, but at other times does both at contrary times." But now that we have passed Gades [?], let us move on to the African coasts.

[Margin: The tides of Africa.] The shores of Africa washed by the Mediterranean experience their own tide, as we have said. Those washed by the Atlantic Ocean, however, experience none that is perceptible until one reaches the Tropic of Cancer; for within the Tropics the sea ebbs and flows, especially beyond the equator, near the river Niger. Indeed, at 11 degrees a flux like the Portuguese one begins and extends as far as the island of São Tomé, which lies under the equator; there, however, it is not greater than the Venetian tide, as Trimarchus heard from ship-masters and reported in Book 2 of the *Meteora*, disputation 1, section 7, and Ramusius [Giovanni Battista Ramusio] says the same (volume 1 of the *Navigationi*, page 126). At Guinea, moreover, the sea boils with the tide with such force that ships can scarcely hold fast with three anchors so as not to be dashed against the shore. The mouths of the river Niger, as Fromondus relates in his *Meteora*, swell for 4 hours and subside for 8; or, to use Scaliger's words (exercise 52): "At Ginega in Ethiopia it comes in for four hours and goes out for eight." Those mouths are 20 miles wide; and Ramusius, too, in volume 1 of the *Navigationi*, page 118, confirms a flux of 4 hours and a reflux of 8.

[Margin: The tide of the Red Sea.] Finally, in the Erythraean or Red Sea (whatever Galileo may deny, since it harms the cause he put forward) the daily tide is so great that, as Scaliger says (exercise 52), the haters of Holy Scripture have dared rashly to lie that Moses crossed over on dry ground, having seized the chance of the ebbing sea. This, however, could not have happened, the same author says, because as far as Suez, a town that lies in the innermost recess, the sea so covers that shore that it never uncovers the sea-bed where the Hebrews crossed. [Margin: Moses made no use of the opportunity of this tide.] Moreover, as Trimarchus points out (Book 2 of the *Meteora*, disputation 1, section 7), between the place the sea reaches when it recedes and the place where Moses crossed dry-shod with the Hebrew people there lie thirty miles and more. Nor could this have been hidden from the Egyptians, who, had they feared a fresh tide coming so suddenly, would not have committed themselves

to it so fearlessly. Now, since we too have crossed with Moses through the Red Sea into Asia, let us sample the more notable features of the Asian tide.

[Margin: The tides of Asia.] The tides of Asia are unknown towards the north, but manifest towards the south and the east. How anxious they made Alexander the Great and his admirals at the mouths of the Indus is related at length by Quintus Curtius in Book 9, [Margin: The tide of the East Indies.] and by Nearchus in Ramusius, volume 1 of the *Navigationi*: for the sea receded with such force that it left three ships stranded on the dry shore, and the tide, returning later, restored them to their course. But pleasant is what Pliny reports in Book 13, chapter 25: "Alexander's soldiers who sailed to the Indians," he says, "reported that the foliage of the sea trees was green in the water, and when taken out it at once dried in the Sun into salt," and so on; and a little after: "In the same tract the tide covers forests of islands, although they are taller than plane trees and the tallest poplars; their leaves are those of the laurel, their flower that of the violet in scent and in colour; their berries, like olives, are themselves of pleasant scent, growing in autumn, the leaves never falling [?]. The smaller of these the sea covers entirely; the tops of the largest stand out, and ships are tied to them, and, when the tide has receded, to their roots."

Of a gulf 60 miles distant from the river Indus, Linscosanus [Jan Huygen van Linschoten] relates (*East India*, part 2, chapter 9) that the ebb and flow of the sea there is the most violent of all [?] that has been seen anywhere, so much so that it was a terror to Alexander the Great, let alone an astonishment. Further, at Calicut, as the Fathers of our Society relate, especially Nicolaus Godignus [Nicolau Godinho] (*De rebus Abyssinorum*, Book 1, chapter 11), and as Trimarchus attests in the section already cited, the risings of the sea are greater at the full moons, whereas at the mouths of the Indus they occur at the new moons. Ramusius adds (volume 1 of the *Navigationi*, page 131) that every six hours the sea there ebbs so far that it leaves ships on dry ground. At the coast of the Ganges the tide is worthy of the mouth of so great a river, [Margin: The remarkable tide of Cambay.] but it is greater on the shores of Cambay. There, as both the Fathers of our Society and most writers on this subject report, the sea pours onto the shore in 2 hours and covers about 30 leagues — elsewhere 15 miles, as Trimarchus has it, and Ramusius (volume 1, page 330) — and with such speed that unless people, warned by cymbals, flee at a run, they are overwhelmed by the tide; and when the sea likewise ebbs in two hours, very many ships are left stuck on dry ground. The inhabitants of that place, however, have in some spots very large pits in which the ships settle until the tide calms, so as not to be swept dangerously out to sea by it; but for this skilled ship-masters are needed, so that the vessels can stay in those pits when the sea ebbs, as Odoardus Barbosa [Duarte Barbosa] relates in Ramusius, in the place cited.

Of the coast of Persia Scaliger (exercise 52) says: "Near the shore of Diuoban-del Rumi an island is sometimes formed; at times it is part of the mainland. That name means Holy Port of the Turks. But neither that return nor that

occupation, with the shores laid free, occurs in all places." In the kingdom of China the river Yanna (a name meaning "son of the sea") undergoes a tide every day as far as Nanchinum [Nanjing], or as far as the lake nearest Nanquinum, although at Pachinum [Beijing] it is felt only at new and full moon. So says our Nicolaus Trigautius [Nicolas Trigault], *De Christiana expeditione apud Sinas*, Book 3, chapter 9. At the Moluccas and the Philippines the sea does not rise more than 3 feet, says Fournier (Book 9, chapter 21).

[Margin: The tides of America.] Finally, the tides of America stand as follows. The northern shores of North America have no tide, but the southern ones have a manifest tide, and at Veragua a strong one. In some places, on the testimony of Ouetanus (chapter 9) and Petrus Hispalensis (part 5, chapter 1), it runs out as far as eight thousand paces; and on the Mexican coast (except, however, the Gulf, which is immune) it is so swift in ebbing that it seems to vanish at once from sight. At the islands of Martinique and the Caribs the sea rises scarcely one foot. Near Cuba and Hispaniola there is no perceptible tide except at the full and new moons, especially in March and September, for then the waters are higher and more agitated. The river of the Amazons, or Marañón, is said to feel the tide and the saltness of the sea for as much as a hundred leagues. On the shores of Peru and of Paria the tide is no small one, and near Panama it covers two leagues. But nowhere is the tide more wonderful than in the Magellanic Strait, where two tides, one from the Atlantic and the other from the Pacific Sea, meeting each other, raise the waters into a heap with a manifest swelling, as Fathers Iosephus Acosta (Book 3 of the history of the New World, chapters 13 and 14) and Alphonsus Ovalius [Alonso de Ovalle] of our Society, in his *History of Chile*, testify. Bartholomaeus Crescentius drew a diagram of this tide (*Nautica Mediterranea*, Book 3, chapter 2), stating that this strait is 100 leagues long and very winding. Sailing on from here to the Archipelago of St Lazarus, one finds a tide which every 12 hours is carried towards the south with such force that it has broken a cable 27 inches thick, as Fournier relates (Book 9 of the *Hydrographia*, chapter 16).

De Diurna Periodo & Tempore Aeſtus.

On the Daily Period and Time of the Tide.

XVII. [Margin: 1. Observation concerning the daily time of the tide.] First. From the common opinion and observation of experts, from the ancient Phoenicians right up to our own times, it is established, generally spea- king, that in the places where there is a tide, as soon as the Moon has risen about one sign above the horizon, the increase of the sea begins. It flows in so that it rises above the banks and, unless their height prevents it, spreads beyond its usual limits towards the land, while at the mouths of rivers it drives their waters back towards their source; and this swelling grows continuously until the Moon has reached the meridian of that place — or rather, as Simon Steuinus [Simon Stevin] thinks, the nonagesimal degree of the ecliptic reckoned from

the horizon. For then the greatest increase occurs, which is usually called *aqua viva*, "living water", or *vivum aquarum*, "the living of the waters". When the Moon, having left the meridian, has begun to descend towards the horizon, the waters of the sea begin to subside and flow back, until the Moon is about one sign from the horizon; for then the greatest decrease occurs. After it the waters stand still for a little while, until, the Moon being one sign below the horizon, they begin to grow again, up to its arrival at the nadir of the meridian — that is, the part of the meridian lying below the horizon in the hidden hemisphere — or rather at the nonagesimal degree of the ecliptic counted below the horizon; at that time there are again living waters and the highest growths of the sea. Next, when the Moon has begun to rise towards the eastern horizon, the waters of the sea begin to subside; and when, before its cosmical rising, the Moon is one sign from the horizon, they sink entirely, and stay in that state until the Moon is raised one sign above the horizon. Thus in the period of one lunar day, which consists of 24 solar hours and ⅘, that is, 48 minutes of an hour, there occur twice daily in the places mentioned the flux and the tide, and twice the reflux and the subsiding of the tide; and in most places the sea rises for six hours and falls for six.

Granted, this rule is not kept in some places. For, as has already been said, the mouths of the Garonne fill in seven hours and subside in five, if we believe Scaliger; or else the sea there rises in 6⅖ hours and falls in 6 hours, if we stand by the Lord of Candal and Fournier. Around the coast of Hippo in Africa the *malinae* and *ledones*, that is, the fluxes and refluxes, behave as follows, on the testimony of St Augustine (*De miraculis Sacrae Scripturae*, Book 1, chapter 7): "The great *malina* boils up for five hours, and for seven hours uncovers the backs of the shores." At the mouths of the river Niger the increases take four hours and the decreases eight; at the coasts of Cambay the tide comes in very rapidly in two hours, and the reflux in two; and in the Chalcidic Euripus the tide once occurred seven times a day, but now four. Finally, in some places it follows no fixed rule, which is regarded as a prodigy, as between Staten and Bergen on the coasts of Norway.

[Margin: A notable passage of Pliny on the tide of the sea.] With this qualification we must understand the words of Pliny, Book 2, chapter 97, which I am pleased to set down here: "Much has been said about the nature of waters; but the flowing-in and flowing-back of the tides of the sea is the most wonderful. It happens in many ways, but the cause lies in the Sun and the Moon. Twice between two risings of the Moon they flow in, and twice they flow back, always in twenty-four hours. First, as the heavens lift themselves up with the Moon, they swell; then, as it declines from the meridian summit of the sky towards its setting, they subside; again, as it approaches from its setting beneath the lowest parts of the sky and the regions opposite the meridian, they flood; and from then until it rises again they draw themselves back." The rest of his words concern the second observation.

[Margin: 2. Observation.] Second. It has been observed that the tide does not begin at the same hour, even in the same place, but later each day by 48^m, because the Moon rises later each day by as many minutes. This is owing to its own proper motion, by which it advances each day towards the east by about 12 degrees, and these require 48 minutes of the diurnal motion towards the west. Therefore, since at Antwerp, at new and full moon, the highest tide occurs at 6^h after midnight, on the following day it occurs only at 6^h 48^m, and on the third day after new and full moon only at 7^h 36^m; and so on, on each of the 15 days that lie between the syzygies of the Moon, the tides are put off by 48 minutes. And although the tides of the sea depend so greatly on the Moon, their turns nevertheless return after hours that are not temporal but equinoctial. [Margin: Pliny's remaining words.] Pliny himself recognised and taught all this, in Book 2, chapter 97, saying: "Nor does it ever flow back at the same time as on the day before, as though the star were pumping [?], drawing the seas with it in a greedy draught, and rising continually from a different place than the day before; yet they reciprocate at equal intervals, and always in six hours — not hours of any given day and night or place, but equinoctial hours. And therefore they are unequal in terms of the common hours, according as more of the measures of day or of night fall into them, and they are equal everywhere only at the equinox. A huge argument, full of light, of the daily alternation, that those are dull who deny that the stars pass beneath the earth and rise again the same, and that from then on a similar face is presented to the lands, indeed to the whole of nature, in the same workings of rising and setting," and so on. Thus the daily period of the tides has as its measure the lunar day of 24^h 48^m.

[Margin: 3. Observation.] Third. It has been observed, as Fournier has it (Book 9 of the *Hydrographia*, chapters 1 and 7), that although some places lie under the same meridian, or very near it, they nevertheless do not have the tide at the same hour. This happens partly because of the situation of the ports — for ports that stretch further out into the sea feel the tide sooner, and are freed from it sooner, than those that have receded inland, especially those set back in oblique bays; partly because of reefs or shallows, sandbanks and similar obstacles; and partly, finally, because of the nature of the soil and of the air, which in neighbouring places is sometimes very different, so much so that one place has the greatest serenity and another the most turbulent air. From the first of the three causes mentioned, the waters surging from south to north fill Bessunda, a port of Spitsbergen, at 3^h European time, and yet in a port a little further up the water is at its highest only at 9^h, although the one is not more than 20 German miles from the other. Thus on the coast of Frisia, on the day of new and of full moon, the living water, or highest tide, occurs at 9^h before noon, and yet at Enkhuizen it occurs at noon itself, and at Amsterdam at 3^h after noon, although these places are very near one another; for Amsterdam lies further within the gulf of the sea than Enkhuizen. So, if the coasts of Britain, Normandy and Picardy are considered, it will easily appear why the tide occurs

an hour sooner on the British coast, which stretches further out towards the west, than in Normandy. From the second cause it comes about that in some places the sea does not grow gradually but, once the obstacles are overcome, suddenly takes its whole increase, and the waves of the surging Ocean roll very swiftly one after another, like barrels, into the ports and onto the shores, so that they outrun the speed of any horse; this is seen at Mont-Saint-Michel near Avranches, on the bank of the Seine, and at the mouth of the Garonne.

[Margin: The error of Petrus Medinensis.] From what has been said it is clear that the rule of Petrus Medinensis [Pedro de Medina], which Crescentius refutes (*Nautica Mediterranea*, Book 3, chapter 3), is false: namely, that the sea fills when the Moon is at Graecus, that is, between north and east, or at Libycus, that is, between south and west, and that, by contrast, it falls when the Moon is at Magister, that is, between north and west, or when it is between east and south. For although this can happen in some places and at some times, it does not happen always or everywhere. [Margin: 4. Observation.] Rather, what the Lord of Candal observed, and Fournier reports from him (Book 9, chapter 1), is true: that the tide of the sea occurs in the same place each day at the same time at which the Moon cuts the same hour circle, that is, the circle drawn through the poles of the world.

De Menſtruis Periodis ac varietatibus Aeſtuum.

On the Monthly Periods and Variations of the Tides.

XVIII. Besides the increases which the sea undergoes every day as the Moon comes to the meridian above or below the horizon, it also at times undergoes greater ones at full moons than at new moons, and at new moons than far from them, and the least at the quadratures or a little after the quadratures; elsewhere, however, it undergoes more at new moons than at full moons. This is so true that even on those shores on which no perceptible tide appears during the whole rest of the month, some swelling nevertheless appears at new or full moon, as happens in the Gulf of Mexico and near Cuba and Hispaniola, and also on some coasts of the Mediterranean, and in that branch of the river Yanson which reaches as far as the city of Pachinum. In some places, therefore, the increases are greater at new moons, as at Calicut; elsewhere, by contrast, they are greater at full moons, as at the mouths of the Indus. In some places, too, the highest increases occur not on the very day of new or full moon, but two or three days after, as at Dieppe and elsewhere, where the tides are greater on the 17th day of the Moon than on the 15th; just as the standing, or middle state, of the waters occurs not at the quadratures themselves but about two days after. Hence that proverb among the Venetians: "From the eighth to the ninth the water does not move; from the twenty-first to the

[Margin: The Venetian proverb on the sea tide [?] around □ ☽.] twenty-second it goes neither up nor down." Rendered into Latin, this runs: "From the eighth to the ninth day the water does not move; from the twenty-first to

the twenty-second it neither rises nor falls." And at that time, as Crescentius says in Book 3 of the *Nautica Mediterranea*, chapter 2, the waters of the sea are called "waters of gall" [aquae fellis], whereas at the time of conjunction ☌ and opposition ☍ they are called "living waters" [aquae vivae]. There he adds, from his own experiments, that the greatest increases of the waters come at the new moon; that from then on they become smaller up to the eighth day of the Moon, when they are at their lowest, and so continue until the 11th day, within which days the smallest tides occur; that from the 11th to the 17th they rise, so that on the 17th day they are at their highest, and from there they fall until the 22nd and so persist until the 25th, within which days again the smallest flows occur.

[Margin: St Augustine's view on the sea tide.] But how the monthly variation of the tides behaves along the coasts of Africa, at Hippo and the neighbouring shores, or even along the shores of the Ocean, we shall learn better from St Augustine himself, in Book 1 [?] of *On the Miracles of Holy Scripture*, chapter 7, whose words are: "Concerning the daily floodings and ebbings of the Ocean the question always arises anew. For this daily flooding is accomplished twice a day, from time to time, always within twenty-four hours, and the alternation of Ledo and Malina accompanies it in alternate weeks. Ledo has six hours of flooding and as many of ebbing. But the great Malina boils up for five hours and for seven hours uncovers the backs of the shores. Yet it shows an agreement with the Moon: it always begins three days and seven hours before the Moon is born, and after the beginnings of the nascent Moon it usually keeps another three days and seven hours. Likewise it begins three days and twelve hours before the full moon, and after as much time again it completes the term of its course. Every common year has six Malinas of each season — of spring, that is, and of summer, autumn and winter — by lunar reckoning, that is, twenty-four in all; except, of course, the embolismic years, which hold twenty-six Malinas." On his view, therefore, a common year of twelve lunations has 24 great tides, twelve at the new moons and as many at the full moons. These begin to rise above the ordinary 3^{d} 7^{h} before the new moon and grow until the Moon is 3^{d} 7^{h} old; but the Malinas, or great tides of the full moons, begin to grow 3^{d} 12^{h} before the full Moon and increase until 3^{d} 12^{h} after the full moon.

[Margin: Scaliger's, [?] and Trimarchus's.] Here I should like to add the words of Scaliger, *Exercise* 52: "Indeed in the quarters there is a calm [malacia], commonly called *calma*; at the full moons the seas are more swollen, so that they seem to lift themselves up out of longing for the star." Now if we believe Iosephus Scaliger, Book 2 of *De emendatione temporum*, page 162, the first Franco-Saxons, who lived on the coasts of Gaul, distinguished the beginnings and ends of the lunar months in no other way than by the tides that occurred at the new moon, so exact and regular were they. Fournier subscribes to this in Book 9, chapter 21, adding that on the coast of Gaul the new-moon tide lasts for two or three days, and then falls until the eighth day, when the water is at its lowest, and stays so until the 11th day; then it rises until the 14th day

and stays so until the 17th; from there it diminishes until the 22nd and stays so until the 25th; then it rises towards the new moon. Trimarchus (*Meteora* 2, disputation 1, section 7) speaks a little differently of the tide of the sea. He says that on the 8th and 21st days of the Moon there is no tide, or the least possible, and that sailors therefore say the water is then tired and languid; but that at the new and the full moon it is greatest, and that sailors therefore call the first the "head of the water" [caput aquae] and the second "living water" [aqua viva]; yet he admits that these things are commonly observed in the Adriatic gulf. Chiaramonti, moreover, says in Book 13 of *De universo*, chapter 22, that at the harbour of Cesenatico sailors call the water that occurs at the quadratures of the Moon "water of gall" and "dead water".

[Margin: Resta's [?] opinion [?].] Franciscus Resta, treatise 1, *De mari*, in his *Meteorologia*, chapter 15, says: "At the interlunium and the full moon the tides are vehement, at the quadratures slack; somewhat fuller at full moon than at new moon."

[Margin: Albert the Great's [?] observation [?] of a single tide [?] in each month [?].] What I said above about the Chinese sea at the mouths of the Yanson also seems to be true of some other sea; for Albert the Great says, in treatise 2 of *De proprietatibus elementorum*, chapter 6: "A sea has been found which comes in from the beginning of the Moon until full moon, and goes out from full moon until the complete failing of the Moon, making in one month only one flow and one ebb."

[Margin: Pliny's [?] authority [?].] Nor is Pliny's opinion on this matter obscure, in Book 2, chapter 97, where he says: "For the lunar difference is manifold, and first in periods of seven days: the tides are moderate from the new moon to the half moon; from that point it overflows more fully, and at the full they seethe most. Then they grow milder, equal to the first ones by the seventh day; and again, on the other side, they increase at the half moon and are equal at the conjunction with the Sun. Plainly, when the same Moon is northern and withdrawing further from the lands, they are milder than when, having digressed to the south, it exerts its force with a nearer effort." He holds, then, that at the new moon the tides are great and at the full moon greater; that from the new moon and from the full moon they diminish for the first seven days of the Moon, down to the first and second quadratures; and that after each of these they take on increases. But he adds: "Yet not at the very moments of time that I have named, but a few days after; just as not at the full or the last moon either, but afterwards."

[Margin: Borro's singular view on the tide at ☌.] Although this is so, Hieronymus Borrus Aretinus [Girolamo Borro of Arezzo], in his dialogue on the flux and reflux of the sea, page 132, nevertheless says that at the new moons the tide is almost imperceptible, and that the Venetians therefore say then that the sea is "in oil" [Mare esse in Oleo], because it stands still just as if it were oil; and yet he concedes that the waters of the sea are then raised so high that they cannot be sailed without danger. But this, he says, comes not from the

tide properly so called but from the storms and winds and similar changes that occur at the new moons; and he adds that on those same days all the humours are greatly altered and give signs of a notable change. To this could be referred what Galen handed down in Book 3 of *De diebus criticis*, referring their changes chiefly to the Moon — although Io. Picus [Giovanni Pico della Mirandola], in Book 3 of *Against the Astrologers*, chapter 16, tries to refute him at length. But it does not seem likely to me that so many other ship-masters and writers would have asserted the greatness of the tides at the new moons unless they had noted it with the sea also calm. And surely the Venetians would be very unskilled to call the sea oil if it were heaved up and tossed by the most turbulent tempests and storms. Unless I am mistaken, then, they mean that the sea is at that time at its highest tide, but in such a way that it keeps that swelling calmly for some time; or else that the tide is perhaps not greatest on the very day of the new moon, but some days after. Yet the same Borro relates on page 175, from observation, that in the first 15 days of the Moon the flows are greater and longer-lasting than the ebbs, but in the remaining 15 days the former are smaller than the latter. So much for the monthly vicissitudes of the sea's tide.

De Periodis & varietatibus Annuis Aeſtuum, alijſque ad annuas reductis.

On the Annual Periods and Variations of the Tides, and Others Reduced to Annual Ones.

[Margin: The period of 8 years of the tides, from Pliny, and on the equinoctial tides.] XIX. Let us begin with Pliny, Book 2, chapter 97, so as to bring some light from his own words. Speaking of the differences of the tides that come from the Moon, after he had indicated the monthly ones, he added: "Over periods of eight years, too, they are brought back to the beginnings of their motion and to equal increases at the hundredth circuit of the Moon, the annual causes of the Sun augmenting all of these: swelling most at the two equinoxes, and more at the autumnal than at the vernal; but empty at midwinter, and more so at the solstice." And before him Tacitus, in Book 1 of the *Annals*, had said that "under the equinoctial star the ocean swells most". But why do these turns not rather return in 19 years, since the Moon and the Sun then return very nearly to the same turns — or at any rate in other lunar periods? We have said more about these in Book 4, chapter 19. But for now we are not inquiring into the cause, being devoted only to the history of the tides.

[Margin: St Augustine's authority on the equinoctial tides.] Let us hear, then, St Augustine, Book 1 of *On the Miracles of Holy Scripture*, chapter 7, speaking of the Malinas, or tides: "Of each Malina of the times already mentioned, the two middle ones — namely the equinoctial ones — and another when either the day or the night completes the term of its course, usually become stronger than usual and higher in flooding; but in the intervening spaces the Ledo is always interrupted again by the same amount." Indeed, if we listen to Trimarchus

(Book 2, *Meteora*, disputation 1, section 7), sailors speaking at least of the Adriatic tides think them greater in winter than in summer, and by day than by night. Franciscus Resta, in his *Meteorologia*, treatise 1, *De mari*, chapter 15, adds from Albert the Great and others that the tide varies with the Moon's nearness to the sea (as we have also learned from Pliny, Book 2, chapter 97, who says that when the Moon has digressed to the south the tides become greater because of the nearer force of the star); with the Moon's nearness to the zenith of those who live by the sea, that is, according as it is nearer to their vertex; and next with its varying relation to the Sun. On longer days, he says, the daytime tides are stronger, and conversely the night tides when the nights are longer than the days; yet in such a way that from the vernal equinox to the summer solstice, and from the summer solstice to the autumnal equinox, the flows are greater than in the rest of the year, but stronger in the lengthening of the days than in their shortening. He affirms, moreover, that the tides are greater when the Moon is in Pisces and at the end of Aquarius, and when the Pleiades assist the Moon. Delphinus, for his part, says in his treatise on this matter that Venus and Jupiter, when near the Sun and the Moon, help to stir up the waters. And Hieronymus Borrus, in his dialogue on the tide of the sea, page 175, says it has been observed that the flows are greater and longer-lasting than the ebbs in proportion as the Sun and Moon stay more hours above the horizon, but that in proportion as the luminaries are more hours below the horizon, the flows are smaller and shorter than the ebbs. I fear, however, that some uncertain things are still being reported about these matters, and from the presumption of conjecture rather than from trustworthy history. But this deserves full credence, which Fournier reports from the observation of the Lord of Candal in Book 9 of the *Hydrographia*, chapter 21: namely, that at the mouths of the Garonne and on the Medoacensian coast the tides are never greater than at the new and full moons that occur in September and then in March, and that the waters are lowest at the winter solstices, and next at the summer ones.

De Regulis Nauticis diſcernendi Horam aquæ viuæ ſeu ſummi æſtus, dato quouis die Lunæ in dato Portu Europæ.

On the Nautical Rules for Determining the Hour of Living Water, or of the Highest Tide, on Any Given Day of the Moon in a Given Port of Europe.

XX. The highest increase of the tide, wherever it occurs daily, depends on the Moon to such an extent, and follows its ascent to the meridian above the horizon, or its descent to the meridian below the horizon, with such fixed steps, that ship-masters long ago drew up for themselves very certain rules by which one can know at what hour the highest tide will come in this or that port, starting from the day of the new and the full Moon and expecting the highest tide each day 48 minutes later than the day before. We shall give a specimen of this, partly from Bartholomaeus Crescentius, Book 3 of the *Nautica Mediterranea*, chapter 3, and partly from our Fournier, Book 9 of the *Hydrographia*, chapters

2, 3 and 4. Crescentius admits that he drew rules of this kind from a certain distinguished Cantabrian ship-master, whom Nicolaus Sagrus of Ragusa, or Epidaurus [Nikola Sagroević], introduces in his dialogues on the tide of the sea. From him, then, we shall reduce into a shorter table the hours at which the highest tide occurs on the day of the new and the full Moon at the places listed below. For once this is known, the hour of the highest tide on the following days, counted from the new or the full moon, will easily be known by adding each day four fifths of one hour, that is, 48 minutes. For example: in the Strait of Cádiz [freto Gaditano], on the day of the new and the full Moon, the living water, or highest tide, comes at $1\frac{1}{2}^{h}$ after midnight and again at $1\frac{1}{2}^{h}$ after noon. So if you want to know the hour of living water for the second day of the Moon, or the 16th, which is the second after full moon, add 48^{m} to $1\frac{1}{2}^{h}$, that is, to $1^{h}\ 30^{m}$, and you will have $2^{h}\ 18^{m}$ after midnight, and likewise after noon. Thus on the third day of the Moon and on the 17th the living water will be there at $3^{h}\ 6^{m}$, both after noon and after midnight, as is clear by adding 48 minutes to $2^{h}\ 18^{m}$; and so on for the rest. We shall give the vernacular names, as he also gives them, since the Latin ones are often lacking or do not correspond exactly, and since on maps it is the vernacular ones that are usually written; and so that no one should take them for Latin, we shall mark them with a distinctive type.

Prima Tabula Horarum Aquæ Viuæ ſeu ſummi Aeſtus die Nouæ ac Plenæ Lunæ, in horis tum à meridie tum à media nocte numeratis, ex Nauclero Cantabro & Creſcentio.

First Table of the Hours of Living Water, or of the Highest Tide, on the Day of the New and the Full Moon, in Hours Counted Both from Noon and from Midnight, from the Cantabrian Ship-master and Crescentius.

Place	Hour of living water on the day of ☌ & ☍ [?], from midnight and from noon
In the Strait of Cádiz, commonly Stretto di Gibilterra, and also in the port of Calesi, and along the whole shore from the Cape of Carteia, commonly Capo di Tariffa, to the cape commonly called Capo di Rutta, the water is full and living at	$1^{h}\ 30^{m}$
From Capo di Rutta to the Cape of S. Maria	$2^{h}\ 15^{m}$
From the Cape of S. Maria to the Cape of S. Vincentius, and from there to the Celtic or Artabrian promontory, commonly Capo de Finis terrae,	
… and over a great part of the Cantabrian coast, commonly Costa di Biscaglia	$3^{h}\ 0^{m}$
On the coasts called de Caccioppi near Bordeaux, commonly Bordeos, and at the places called Las Bollienas and Ollona	$2^{h}\ 15^{m}$
In the straight run between La Rochelle, commonly Roccella, and the Isle of the King [Insulam Regis], which lies by the promontory del Plomo, up to the cape called Raso di Hontenaut	$3^{h}\ 0^{m}$

Place	Hour of living water on the day of ☌ & ☍ [?], from midnight and from noon
From the place called il Forno to the island di Hebas, in the run of the water	3^h 45^m
But in the ports beside these runs of the waters it comes later, namely at	4^h 30^m
From the island Hebas to Carnesule and at the place called Caschetti	5^h 15^m
But at the places on the mainland of France that face the three places already mentioned	6^h 15^m
From the place Carnesul through all the ports, shores and capes of Normandy and Picardy, as also at the places Blancarnes, Cales and Neuport	9^h 0^m
But in the middle of the Channel between France and England, off the places already mentioned, from Carnesul to Blancarnes	12^h 0^m
But from Cales to Neuport, in the run of the water ten miles out from land, the living water comes at	0^h 45^m
From Cales to Gravelines, in the run of the water	1^h 30^m
From Gravelines along the whole coast of Flanders, and in the island of Zeeland	3^h 0^m
But in the run of the water beside the coast already mentioned	3^h 45^m
On leaving Flanders towards the Channel of England: although the water is full at hour 3 on the shore and at 3^h 45^m in the run of the water, yet the further you withdraw from the shore towards the cape called de Dobla, the water will be full at hour 3, but in the run of the water at 4^h 30^m; and this course of the water, until it tires, lasts from Zeeland to the cape called di Monge, or as far as las Motricas	
At the place called Godoina and at Duna on Cape Dobla, up to Capo di Romaneus, on the shore, that is, and in the ports	9^h 0^m
But in the course of the waters	12^h 0^m
On Capo di Romaneus, and in the port Cameracensis, or de Cambray, and along the whole neighbouring coast	9^h 45^m
But in the run of the waters off the places already mentioned	11^h 15^m
At Erlaga, Beuceppe and the bay called di Soran, and along the whole coast that extends from the cape of Erlaga to the island called di Vuicche	10^h 30^m
But in the run of the water beside the coast already mentioned	12^h 0^m
Before you enter by the mouth of S. Lena to the island di Vuicche, you will find two syrtes, or sandy shallows, one called Almages and the other Ostriar, where, as also in the port Porceinua, the water is living at	11^h 15^m
In the Channel itself, between the island Vuicche and England, there are three syrtes, one called Zenciuiglia, another Ambra and the third Calzesores, where, as also in the port of Antona, the water is full at noon itself and at midnight, or	12^h 0^m
At Giaramua and at the point, or Aguglia, di Vuicche	9^h 15^m
But the water runs further still, up to hour 11¼	11^h 15^m
From the Aguglia already mentioned to Cape Porlan, and on its coast and in its port	9^h 30^m
But in the run	11^h 15^m
From Cape Porlan to Cape God-Esterch, in the run	10^h 30^m
But in the port Artemua and on the neighbouring shore	8^h 15^m
From Cape God-Esterch to Cape Lisuarte, in the run, that is	9^h 0^m
But in the ports di Plemua, Faiut, Falamua	7^h 30^m
From Cape Lisuarte to the Cape of Cornoualia, so cal-	

Place	Hour of living water
led Lungosneus, which is the chief cape of England, in the run of the water	$7^h\ 30^m$
At the place called Pesanz and Musol	$6^h\ 15^m$
In the ports of all the Surlingan islands	$4^h\ 30^m$
But outside their ports, at the capes of the islands	$6^h\ 0^m$
On the coast of Ireland, at the place called Manga di S. Giorgio, at the entrance di Duolin	$10^h\ 30^m$
In the port di Mirafurda	$5^h\ 15^m$
In the island dell'Hondectenebi, and at the place called Los Olmos	$6^h\ 0^m$
In the port di Patristo	$5^h\ 30^m$
At the place called Quinque Roda, and at another called Ancia Pristol	$6^h\ 45^m$
In the city called Galuei, as far as Gafurda, and in their ports, as also in Semerich, in … Tingle, in S. Michaele, in Baiam, Balensemor, Guinzala, Corca, Iiocla and Gattafurda, the water is full and living on the days of the new and the full Moon at	$4^h\ 30^m$

So much from Crescentius and that distinguished Cantabrian ship-master. There now follows another table, from Father Georgius Furnerius of our Society, Book 9 of the *Hydrographia*, chapter 2. We shall reduce it to another form, a little clearer unless I am mistaken, adding capital letters at the head of the former table, so that by means of them we may indicate, in the other part of the table, which places belong to such a position and time of full water. We shall teach the use of the table in numbers XXI and XXII.

Second Table of the Hours of Living Water, or of the Highest Tide, on Any Day of the Moon in the Ports Listed Below, from Father Georgius Furnerius of the Society of Jesus.

Part I of the table

Day of the Moon	Day of the Moon	A	B	C	D	E	F	G	H

Loca Reſpondentia literis in fronte tabulæ poſitis.

The Places Corresponding to the Letters Set at the Head of the Table.

Let-ter	Places	Hr	Min
		On the day of the ♂ and ☍ of the ☾, high water is after noon and after midnight:	
		Hr	Min
A	At the island of Jutland; off the coasts of Heuer, Eyder and the Elbe at Emden. Off Enkhuizen and Horn. Along the whole coast of Flanders, in England. At the river de Beuechier at Porshmout; at Hampton and Baruich. In France at Honfleur and at Caen. In Barbary, beyond Cape Quintin as far as Boiador. Above these stretches the tidal streams come down from Nesse as far as Boulogne.	12	0

Letter	Places	Hr	Min
B	Within the Meue at Camp Vere, at Vlissingen and Middelburg, at the coasts of Beuesier in the sea at Vinckelzee, in the sea of Garcenzey. Above these stretches the streams of the surging or ebbing sea come down from Boulogne, into the Somme.	12	45
C	Off the Meuse, that is, the Mosa, and Goeree; off Vere on the coast of Zeeland, off the Thames, and off Iarmuyen towards the western side of Vuict, at Morbian, off Blauet, at the Fair Island, and beyond these stretches as far as Cape Quentin. The tidal streams, moreover, flow down from Gravelines to Boulogne.	1	30
D	At Houge, outside the Ras de Fontenas; above the Fair Island; off Vuielingue; off the Meuse, that is, the Mosa. The tidal streams flow down between, through the middle, to Calais, and beyond Gravelines as far as Duncherquen, and from Caen as far as Estaples.	2	15
E	At Amsterdam, Rotterdam and Dort, outside the Shoals of Flanders, at the point off Conquet; at the mouths of the Garonne; on the southern coast of Britannia among the Pictones, that is, Poitou; in Aquitaine, commonly Guascogna; in Cantabria, that is, Biscaglia, in Galicia and Lusitania, and on the southern shore of Ireland. The tidal streams come down beyond Cape de Hague as far as the island of Ornay, and from Garnzeu to the Quasquettes.	3	0
F	Within Caletum, or Calais, and the Mosa, or la Meuse, at Rouen, at S. Mahe, at Rupella, commonly Rocchelle, at the Cassiterides islands, now the Sorlinges, at Venta Belgarum, now Bristou. In the harbours and on the shores of Aquitaine, that is, Gascony, in Galicia and Lusitania, and on the western coast of Ireland. The tidal streams, moreover, rush from Stuissart to Diepen.	3	45
G	From Thessel as far as Caletum, or Calais, at S. Paulus, or S. Pol, outside the harbour; between Garnezer and the Seven Islands; outside Four, and on the southern coast of Ireland. The tidal streams run and come down from Barfleur to Stuissart.	4	30
H	At Plemuda; in the sea of Galles, at Dormuda and Valmuda, at Mulfortium in the southern harbours of Ireland. The tidal streams roll down from the island of Basau, Cape de Four and the Cassiterides, or Sorlingues, to Cape Lysart, and from Portland to Vuicht.	5	15
K	At S. Malo, at Cancalen, at Antwerp, or Anuers, and off it at Bremen, at Hamburg, commonly Hamborg; at Thessel, at Goësan, or Goës, at Gouda. The tidal streams flow down from the headland, or promontory, of England to Lezordia.	6	0
L	At Bristol, or Bristou, at Cay between Foye and Valmuda, off S. Nicolaus. The tidal streams come down from the island of Bas to Matuanem along the length of the land.	6	46
M	At Thessel above Raden, at Lezarda near land by Pleymouth, in the sea at Passage. The tidal streams arrive descending from Barfleur to the Cape of the Seine.	7	30
N	Outside the Quasquettes near Vuicht, and from Vuicht to Beuesier near land, outside Vlie. The tidal streams come down from behind Garnozey and within the Seven Islands.	8	15
O	Within the Seine, or La Seyne, at the Ras of Portland; on all the shores of Friesland, between GarneZaij and les Quasquettes; and at Cherebourg. The tidal streams, having slipped down, reach between Morlaix and Octobers.	9	0
P	Near Garnezey, at the channel next to Lesartia, at Iarmouth, at the point or tip of Vuicht. The tidal streams flow down off Cancale.	9	45

Let-ter	Places	Hr	Min
Q	At Diepen and S. Valerius, at Fesqua, and the greater part of the shores of Picardy and Normandy, and at Senegal. The tidal streams come down from Barfleur to Alborga.	10	30
R	Off the Thames, at Hansonna and at Estreham. The tidal streams come down beyond Fontenay as far as Cape de Four.	11	15

Vſus Præcedentis Tabulæ.

The Use of the Preceding Table.

XXI. Across the head of the preceding table run three bands. In the first are large characters in alphabetical order; they denote the places belonging to that column, which are to be indicated after the tables by the same characters. In the second are the points of the winds, following the more recent ship-masters, by which these men have been accustomed to indicate not only the situation of places but also the hour of the tide on the day of the new and the full Moon: they assign three hours to each of the eight rhumbs, 1½ hours to half a rhumb, and three quarters of an hour to a quarter of a rhumb. So when they want to express that full and high water occurs at Amsterdam or Rotterdam on the day of new and full Moon at 3 o'clock after noon and at 3 after midnight, as you see in Column E, they say that Amsterdam and Rotterdam lie Sud Ouest and Nord Est; this is indicated by the initial letters S O and N E set in the second band of the head. If you wish to know the winds and points indicated by these letters, consult our tables 2 and 3 set out in Book 2, Chapter 17. Where this fraction ¼ stands, it signifies one quarter of the next rhumb. If anyone does not wish to use this mode of indication, he may omit it, since it is not at all necessary to the reader. Finally, in the third band of the head stand the letters H. M., signifying Hours and Minutes, that is, sixtieths of an hour.

Moreover, in the 1st and 2nd parts of the table there are ten columns. The first of these contains the first 15 days of the lunation, counted from the ☌, that is, from the day of new Moon; the second the remaining 15 days, counted from the ☍, that is, from the full Moon. The rest contain the hours at which the highest tides, or high waters, occur in the places indicated by the capital letters of the 1st or 2nd head, corresponding to the age of the Moon, that is, to the days counted from new Moon or from full Moon. With these laid down, we shall teach, following Fournier, how to solve the principal hydrographic problem by means of the table already mentioned, or also by Crescentius's table.

Problema. Dato Die Lunæ, ſcire Horam Aquæ viuæ ſeu ſummi æſtus, in dato Portu aut littore.

Problem. Given the Day of the Moon, to Find the Hour of High Water, or of the Highest Tide, in a Given Harbour or on a Given Shore.

XXII. Look up in the catalogue of places the place you are in doubt about, and see which of the initial letters it belongs to. Then look for that initial letter in the topmost head of the first or second part of Fournier's table: in its column, opposite the given day of the Moon, which is marked in the first or second column, you will find the hour, both after midnight and after noon, at which the highest tide occurs in that place. [Margin: Example of the problem.] EXAMPLE: We wish to know at what hour the highest tide occurs at the mouths of the Garonne on the day of new and full Moon, or also on the 4th day.

If you run through the catalogue of places, you will find that the mouths of the Garonne belong to the letter E; this letter is found above the seventh column at the head of the first part of the table. Going down that column, then, you will see opposite day ☌ 0, that is, the day of new Moon, and opposite day 15 ☍, that is, the day of full Moon, the hour 3 0; but opposite day 4 after new Moon, the hour 6 12′. Conclude, therefore, that at the mouths of the Garonne the highest tide occurs on the day of both new and full Moon at 3 o'clock after midnight and again at 3 after noon; but on the 4th day of the Moon (to which day 19 also corresponds) it occurs at 6 hours and 12 minutes, that is, one fifth of an hour, after midnight, and again at 6 12″ after noon.

[Margin: The way to check the figures of the table.] If you use Crescentius's table, in which only the hours of the highest tide on the day of new and full Moon are marked, and you are concerned about other days, multiply 48′ by the number of days, that is, of the age of the ☾, and divide the sum by 60. Add the quotient of the division, with its fractions if there are any, to the hours of the highest tide at new or full Moon, and subtract 12 hours from the sum if it exceeds them; the remainder will give the hour of the highest tide for the given day of the Moon. In the example adduced a little earlier, the 4th day of the Moon is given, and the hour of the highest tide at the mouths of the Garonne on the day of new Moon is 3 o'clock. Multiplying 48′ by 4, then, gives 192 minutes; dividing these by 60 gives a quotient of 3 hours 12′; adding this quotient to 3 hours gives 6 hours 12′, as above. And this is the way to check the figures of Fournier's table, in case some error has crept in through the fault of the printers — as we found more than once that one had crept into Fournier's table, and corrected it.

Indicantur Opiniones de Cauſa Aeſtus Maris.

The Opinions on the Cause of the Tide of the Sea Are Set Out.

XXIII. Our Causinus, in his *Dogma de Resurrectione*, commending the divine works of the first week, said very sharply that the flow and ebb of the sea is *the grave of human curiosity*. For no schools, says Simon Maiolus [Simone Maioli] in Colloquy 10 of the *Dies caniculares*, have yet untied this question sufficiently. Not without reason does Julius Caesar Scaliger begin this treatment in Exercise 52 with these words: *Perhaps silence would have done more for the opinion of a*

good reputation than boldness. For what I am accustomed to proclaim everywhere, that we know nothing, suits above all this inquiry, which treats the motion of the sea; and further down: *Now some god from the machine* [Greek: θεὸς … ἀπὸ μηχανῆς (theos … apo mēchanēs, "a god … from the machine")] *must be called up by us. For who would not say that in this matter philosophy itself stammers?*

[Margin: The difficulty of knowing the cause of the tide, but more so of the ebb of the sea.] The ebb of the sea seems much more difficult to explain than its flow. For this reason St Augustine — having said, partly in Book 7 of the *City of God*, chapter 22, and partly in Book 1 of *De mirabilibus Sacrae Scripturae*, chapter 7, that the Romans consecrated two goddesses to this matter, namely Venilia, or Malina, for the flow of the sea, which the Italians call *Marea*, and Salacia, or Ledona, or Lidona, for the ebb — said: *But the flooding of this rational persistence, the one that recedes, is hidden from our minds; human knowledge prepares no less progress for those who do not know.* And a little later: *We are permitted to observe the swellings of the sea as it floods, but we are deprived of understanding of it as it recedes.* To these add the verses of Lucan adduced in Book 2, chapter 15, at the end of Scholium 5.

And truly the features of this motion are so varied and so wonderful that they will always seem to defeat every effort of the human mind, whoever wishes to investigate their sufficient cause and reason and, having investigated it, to explain it. [Margin: The heads of the difficulty, and a summary of the wonders in the tide of the sea.] For what mortal could explain why a large part of the sea lacks a tide, when a large part is likewise subject to one? Why it displays such dependence on the Moon, and yet, when the Moon is silent at new Moon or lies hidden below the horizon, the same tides return, or greater ones? Why in many places the flow is completed in six hours and the ebb in as many, and yet in some places the rise takes about seven hours and the fall five, as roughly at the mouths of the Garonne; elsewhere the waters flow in for four hours and flow back for eight, as at the mouths of the Niger and the coasts of Guinea; elsewhere, as on the coast of Cambay, they burst in very rapidly in two hours and in two hours flee back and are swallowed up again? Why, again, in other places fifteen whole days are required — namely from new Moon to full Moon — for the fullness of the waters, growing continuously, to reach its highest increase, and as many days for them to subside, namely from full Moon to the following new Moon, which happens in the Chinese sea at the mouths of the river Pachinensis, and also in some seas around Cuba and Hispaniola? Why, moreover, at the mouths of the Indus the tides are greater at full Moon than at new Moon, while near Calicut, on the contrary, they are greater at new Moons than at full Moons, but universally they are greater at new and full Moons than at the quadratures? Further, why, in harbours or river-mouths lying close together and almost on the same meridian, the highest tide nevertheless occurs some hours sooner at one than at the other? Besides, why in some places the Ocean swells so proudly that it rises with its tide by 80 cubits, as in Britain, while elsewhere, as at Marseille, Ancona and Rimini, they

scarcely rise to a foot or a foot and a half? Finally, who could relate why, of the wells at Gades and at Seville, some rose with the tide of the sea and sank with its ebb, some did the reverse, and some behaved in both ways at different times? We have chosen to gather all these truly wonderful features of the sea's tide into a single summary, so that we need not repeat them so often when we review the individual opinions to show their insufficiency.

[Margin: 1. The opinion of Timaeus and Chiaramonti.] XXIV. The first opinion, that of Timaeus in Plato and in Plutarch, Book 3 of *De placitis philosophorum*, chapter 17, assigns the cause to rivers. *Timaeus,* says Plutarch, *alleges as the cause the rivers that burst through the mountains of the Celts into the Atlantic: by thrusting the sea forward with their impetus they stir up the tide, and conversely, when the impetus slackens, they drive the sea back again and make the ebbing tide.* This very opinion of Timaeus was quite recently revived by Scipione Chiaramonti in Book 13 of *De universo*, chapter 22, but embracing all rivers, not only those of the Celts; and he adds that by the dashing of the waves against the shores the water is thinned into exhalations and vapours. Since, therefore, the waters of the rivers continually flowing in produce so great an increase that the motion that occurs either in the ebb or in the interval between flow and ebb is not enough to evaporate them, the waves of the sea must swell and cause the tide; but from this very swelling they collide with one another with greater motion, and the evaporation increases from that, until the water that was in excess, thinned into exhalations, decreases and appears to flow back. For since he believed he had shown earlier that the tide of the sea arises from an increase of the waters, and yet not from rarefaction, he argued that it can arise from no other source than the water of the rivers flowing in, since water naturally increases in no other way than either by rarefaction or by the addition of water to water, through a new generation of waters or through their inflow and concourse into one place. And in chapter 26 he accordingly asserts that on the coasts of the Ligurian and the rest of the Tyrrhenian sea no perceptible flow occurs, because few and small rivers enter that sea. As for why the tide is smaller at the Moon's quadratures than on the days nearest to new and full Moon, so that the waters are then called "waters of gall" [aquae fellis], he gives the cause in these words, supposing, from Ptolemy, that the Moon is then nearer to the Earth: *The motion of the water of the sea, as it glides onto the shore and glides back, is due to evaporation, as I said before. In the waters of gall the approach is greater than in the flow, smaller than in the ebb; and as it glides back, the falling back is greater than in the flow, smaller than in the ebb. The collision for evaporation is therefore smaller than in the flow, but greater than in the ebb; for this reason, that the Moon is nearer the Earth, it helps the water towards evaporation more than when it is more remote, and therefore a smaller collision of the waves suffices to dissolve the same amount of water into vapours.*

[Margin: Refutation of the 1st opinion.] XXV. But against both opinions there are many and most evident arguments. For the tide would have to occur on the opposite banks towards which the rivers would thrust the water; and

so the Celtic, or Gallic, rivers would raise a tide at the islands and mainlands lying opposite, towards the west of Gaul. And where the waters of two great rivers meet each other head-on — say, the river Niger flowing from Africa towards America, and the river of the Amazons flowing from America — there, that is, in the intervening sea, a greater tide and heaping-up of waters would occur than at the shores. Moreover, since very great rivers enter the Caspian Sea, a very powerful tide would have to occur on its shores or in its middle. Further, the tide would have to increase continuously, just as the rivers run down into the sea continuously, and indeed more in spring than in autumn, because of the abundance of melting snows. All of this is false. In addition, the very mouths of the rivers, rather, suffer the tide from the sea, and are driven back by it towards their springs: when the sea flows in, the rivers flow back, and when it flows back, they flow. So Franciscus Resta [Francesco Resta] sharply noted against Timaeus in Book 3 of the *Meteorologia*, tractate 1, chapter 16, adding that there are many seas which receive great rivers and yet have no tide, or do not have a tide proportionate to the size of the rivers. Vicomercatus [Francesco Vimercati], for his part, used to object to Timaeus the scantiness of the water the rivers carry into the sea, which is unfit to raise so vast and wide a surface by a perceptible increase. Chiaramonti, on the contrary, in Book 13 of *De universo*, chapters 17 and 19, undertakes to demonstrate that the water brought in by the rivers bears a perceptible proportion to the water of the sea. In chapter 17 he supposes, for good measure, that the Earth is covered with waters on every side, and that their depth everywhere is one Italian mile; that the semidiameter of the Earth alone is 3034 Italian miles, but with the water 3035, and so the diameter is 6070. He makes its ratio to the circumference 7 to 22, and therefore the circumference 19,077 miles. From this, by Archimedes' rules, he gathers that the solidity of the terrestrial sphere together with the waters is 117,142,218,733 cubic miles. [Margin: The quantity of the water of the sea, by Chiaramonti's calculation.] Likewise, taking the diameter of the Earth alone as 6068, he gathers a circumference of 19,070 and a solidity of 117,033,475,546 cubic miles. Subtracting these cubes from the former, therefore, there remain for the water alone 108,743,187 cubic miles, so that the Earth alone contains the water 1076 times. But because only half of the Earth is covered with waters, and even this half is not everywhere one mile deep but at most half a mile, only a fourth part of the preceding sum actually falls to the water of the sea, namely 27,185,797 cubic miles. In chapter 19, to investigate the quantity of water that the rivers carry into the sea, he uses the river Arno, on which, he says, boats travel from Florence towards Pisa as far as Callo, 40 miles distant, in 8 hours when the river is moderately fast, and that without oars or sails. So that water covers 40 miles in 8 hours, that is, 13,333 perches (for he gives a mile 333⅓ perches), and therefore completes a single perch of length in at most two seconds of an hour. Now let the Maragnon have the same velocity; its width at the mouth is 70 leagues, that is (says Chiaramonti), 105 miles, or 35,000 perches; and let its depth likewise be one perch everywhere at the mouth. Then the

Maragnon will pour out 35,000 cubic perches in two seconds of an hour, and in a whole year 3,030,480. What of so many other rivers of the whole world?

In the calculation just described, however, considering the water the rivers bring in over a whole year is superfluous, since the tide of the sea occurs in many places daily, and every twelve hours. One ought therefore to have considered the water brought in in 12 hours, or at most in one day. Then, to establish what proportion it bears to the water of the whole sea, one ought to have gathered a more probable sum from all the rivers of the world, at least those described in geographical maps and histories, and compared it with the water of the sea. We have done this elsewhere, in a complete little work shared with judicious men, which we shall perhaps publish in Volume 2 of the *Almagest*, Book 4, which will be the geographical book; and we showed, with the greatest probability, that all the known rivers taken together do not pour more than 150 cubic miles into the sea in 6 hours. [Margin: The quantity of the sea, by our calculation.] Distributed into paces, or cubic feet, these would make 150,000,000,000 paces, and 18,750,000,000,000 feet. Now, from what was said in Book 2, chapter 14, the surface of the terraqueous globe is 336,434,176 square Italian miles. Half of it, therefore, as we said in the same place, falls to the surface of all the seas taken together, namely 168,217,088 square miles, [Margin: The tribute of the rivers carried into the sea.] which make 168,217,088,000,000 square paces, that is, 4205,427,200,000,000 square feet. Dividing these by the whole tribute of the rivers, which is 18750,000,000,000 cubic feet, the quotient comes out as 224, neglecting fractions. If, therefore, the water of the rivers were to be distributed over each foot of the sea's surface, added at an equal height everywhere, the height of water falling to each foot would be a 224th part of a foot — scarcely the thickness of a grain of barley. So far is that water from being able to produce the tide of the sea; and much less still, if the sea transmits a great part of the water it receives from the rivers through subterranean passages to another neighbouring sea, and that sea to other abysses, as Fournier learnedly discusses with regard to the Caspian and the Mediterranean in Book 9 of the *Hydrographia*, chapter 6.

[Margin: 2. The opinion of Plato.] XXVI. The second opinion was that of Plato himself, who attributed the tide of the sea to waters alternately bursting out of Tartarus, or the abyss, and being swallowed back. Plutarch says this of him in Book 3 of *De placitis*, chapter 17: *Plato ascribes the cause to a certain lifting: for the waters are raised up by the opening of a certain cave and flow out widely, and then flow back into the same place, and from this the surging seas are tossed.* [Margin: Refutation of the opinion [?].] But from this the cause can be given of almost none of the features we reviewed at number XXIII, and especially not of those connected with the phases of the Moon. Granted — let us not deny it — that there are deep abysses of waters in the bowels of the Earth, and that their whirlpools contribute something to the variety of the tides; and Philippus, as cited by Resta, refers to this the words of Job, chapter 38, in the reading of the Seventy translators: *Have you entered into the springs of the sea?*

[Margin: 3. Opinion, and that of Pandulfus Sfondratus.] XXVII. The third opinion was that of Pandulfus Sfondratus [Pandolfo Sfondrati], in a treatise on this subject. He attributes the tide to the motions of the sea from east to west and from north to south, because so much water cannot pass at once through the narrows of the Strait of Gades, of the Strait of Magellan and the like; and he says that these motions of the sea occur so that it may run to make up what the Sun has consumed into vapours, and to keep the sea in its equilibrium. [Margin: Refutation of the 3rd opinion.] But the tide of the sea is far different from those two motions, and has far more wonderful and different features, of which no reason can be given through the motions just mentioned alone. And truly, since the Pacific does not run eastward before the tide, it cannot be the cause of the tide in the Strait of Magellan that comes from the Pacific Sea. Nor can the sea's course towards the north be the cause of those huge flows that occur at the coasts of Britain, since the sea rather runs from the north towards the equator — and not in alternating spells of six hours, but perpetually.

[Margin: 4. The opinion ascribed to Io. Picus and Buccaferreus.] XXVIII. The fourth opinion is attributed to Io. Picus and Buccaferreus [Ludovico Boccadiferro], on the ground that they refer this effect to the diversity of the shores, which resist and repel the waters, and to the differing slope of the basins in which the sea is contained — just as in a shaken vessel the water floats this way and that towards the sides unevenly, according to the vessel's bottom and its differing rims. But of Io. Picus's opinion shortly. Meanwhile, whoever's it may be, it is shown to be insufficient by the connection of the sea's tide with the Moon and by the features enumerated at number 23. [Margin: Refutation of the 4th opinion.] Add that, while the tide occurs on one shore, an ebb would have to occur from the opposite shore, which, however, no history confirms.

[Margin: 5. The opinion of Adelandus, approved by Picus.] XXIX. The fifth opinion was that of Adelandus, speaking from the opinion of the Saracens. Io. Picus writes of him thus in Book 3 *Against the Astrologers*, chapter 15: *Since,* he says, *the arms of the sea themselves — those, namely, that the interposed mass of land divides — hasten with a hurried impetus to meet and flow together, it comes about, both from the interposed mountains and from the very situation of the land, that while they fall short of that same course they are carried back, and that from there they are recalled, by the very situation of the place, to where both a paternal and a natural motion impels them.* And a little later Picus says: *This opinion of his is not greatly at variance with likelihood, since the parts of each element are borne by a natural propensity towards their own wholeness. What wonder, then, if, shut off in place by the lands lying between, and present, they strike the shores of the Ocean as they come up while they eagerly seek to run together, and, repelled by the obstacle, likewise draw back? With this cause removed (as happens in the southern ocean), we see that these tides do not appear.* Besides the differing situation of the shores, therefore, these authors suppose a natural propensity of water towards mutual concourse and, as it were, embrace through the arms of the sea, so that the parts may be preserved with their whole. [Margin: Refutation of the 5th opinion.]

But against this opinion, besides the connection of the sea's tide with the Moon and the effects reviewed at number 23, there are the arguments of Franciscus Resta, Book 3 of the *Meteorologia*, tractate 1, chapter 14, and of Cabeo, Book 2 of the *Meteorologica*, text 6, question 6. For if water seeks union with other water, and the tide occurs for that reason, it ought to occur also in lakes, pools and the Caspian Sea. Next, since, apart from the Caspian, the other seas are already continuous, what need was there of a greater union? And in what part of the sea, after all, must this union take place? Besides, there are no further seas on this side of those shores at which the sea nevertheless makes a tide by approaching them: for either the tide stops at the banks, if they are low, or, overflowing above them, it covers the shores, so that the sea seems rather to seek union with the land than with water. For what sea is there on this side of the Venetian, Gallic, British or Indian coast? None, certainly. And yet to these coasts there flows in, with so great a tide, the sea. It seems, then, rather to flee the waters that are in the middle of the ocean, and to be separated from them by a kind of sedition, than to be joined to them — unless perhaps it repents of that sedition and, by flowing back, rolls back to the place it had withdrawn from. But if you say that near the shores there is a friendly and sympathetic water with which it wishes to be joined, then let it cling to that water once it has joined itself to it, and not be parted from it by flowing back. But enough has been said against this fiction.

[Margin: 6. The opinion of the Stoics and of Apollonius of Tyana.] XXX. The sixth opinion was that of the Stoics, as reported by Solinus, chapter 36. They held that the world is an animal, and that through chasms of the earth close to the floor of the sea, as though through bodily nostrils of breath, it alternately sucks the waters back and blows them out, by a reciprocal inhaling and exhaling, and so stirs up the tide as if panting. So too Apollonius of Tyana attributes the same to spirits panting beneath the sea; and that animal faculty which Kepler attributes to the whole globe, compacted of earth and water, favours them not a little. Cabeo rises against this fiction with several arguments, Book 2 of the *Meteorologica*, text 6, question 6; [Margin: Refutation of the 6th opinion.] but it is enough to have enumerated the features of the sea's tide, connected chiefly with the Moon, as we did at number 23: for it is at once apparent that those effects cannot be produced by this panting, however great the soul. Rather, someone might attribute this to the inhaling and exhaling of the Moon, an opinion St Basil mentions in Homily 6 on the *Hexaemeron*, saying: *The sea, as if by the exhalations of the Moon, is drawn backward, and by her breathing-in again is driven up to its proper measure.*

[Margin: 7. The opinion of Alpetragius and of certain Arabs.] XXXI. The seventh opinion attributes the tide of the sea to the diurnal motion, which sweeps all things along with it. So certain Arabs, as reported by Albert the Great, *De proprietatibus elementorum*, tractate 2, chapter 6, and among them Alpetragius, if we believe Io. Picus, Book 3 *Against the Astrologers*, chapter 15. But if this opinion were true, the flow and ebb would occur only in the

direction of longitude, [Margin: Refutation of the 7th opinion.] and would be greatest under the Equator; nor would the vicissitudes of the lunar motions produce so great a variety of tides. Besides, it is false that the sea is swept along by the diurnal turning of the heaven, especially once the fluidity of the heavens is posited, for which enough was argued in Section 1 of this Book, chapter 7.

[Margin: 8. Opinion, likewise of Io. Picus.] XXXII. The eighth opinion, which Io. Picus adduces in second place in Book 3 *Against the Astrologers*, chapter 15, refers the cause to vapours and winds stirred up from the denser water: from these come turmoil and violent motion, and from that comes heat seeking more room, and from that the tide; and when this has cooled, the seas are laid flat and subside. [Margin: Refutation of the 8th opinion.] But since Picus is wholly occupied there in excluding the Moon, and yet so great a relation of the tides to the Moon is confirmed by history, he ought to have shown how, without the Moon, the vicissitudes of the tides are nevertheless adjusted to the Moon's motions. Add to this that even a calm sea, stirred by no winds, is nonetheless subject to the tide; indeed, when a violent storm comes on, the tide properly so called is diminished, as Trimarchus affirms, Book 2 of the *Meteorologica*, disputation 1, section 7.

[Margin: 9. The opinion of Thomas Lydianus.] XXXIII. The ninth opinion attributes the tide of the sea to ebullition, but ebullition caused by heat and subterranean fires — to which I, as a younger man, had ascribed a large part of this cause. So Thomas Lydianus [Thomas Lydiat], as reported by Fromondus, says that a fire lies hidden beneath the floor of the sea and kindles the abundant bitumen present there, so that the sea swells as the fire exhales. And although Franciscus Resta, Book 3 of the *Meteorologia*, tractate 1, chapter 14, does not think it improbable that the tide is a kind of ebullition of the sea, like that of boiling water, produced by spirits and breaths rising from the sea floor — for if a spirit shut up in the earth stirs up earthquakes and moves the earth, how much more easily can it move the waters and raise them — he nevertheless afterwards drew back from this view. [Margin: Refutation of the 9th opinion.] For the necessity always remains of giving the reason why the tides occur with those vicissitudes preserved which we reviewed at number 23, and why they receive their laws from the Moon in so many effects. Cabeo adds, Book 2 of the *Meteorologica*, text 6, question 6, that motions produced by fire are lawless and tumultuous, as appears in earthquakes, in Vesuvius, in Etna; but tides are periodic and return at fixed times. Finally, against this opinion stand the arguments against rarefaction to be adduced at number 37.

[Margin: 10. The opinion of Lessius.] XXXIV. The tenth opinion has recourse to Intelligences, which, just as they are the movers of the heavens, are also the movers of the seas. This opinion is attributed by Fromondus to Leonardus Lessius [Leonard Leys], who asserts that the Intelligence presiding over the waters is called in the Apocalypse "the angel of the waters". On this occasion Franciscus Resta, in the passage just cited, says that it could also be attributed to evil spirits, since of Behemoth, that is, an evil demon, it is

said in Job 41: *He will make the deep sea boil like a pot, and will make it as when ointments boil.* But this opinion has not been accepted, for three reasons. [Margin: Refutation of the 10th opinion.] First, because it has recourse to a machine without necessity, or out of weariness with inquiring into the proper cause in nature. Second, because the tides of the sea are irregular in many places, and so do not seem to be the work of an Intelligence. Third, because the sea's tide is altogether lunatic [Lunaticus], that is, adjusted to the vicissitudes of the Moon; so it seems that recourse should be had to the Moon rather than to an Intelligence — and to the Moon, in the end, most authors have recourse, though without excluding the Sun, as we shall soon see.

[Margin: 11. The opinion of Pliny and Pytheas.] XXXV. The eleventh opinion, then, throws the tide of the sea back onto the Luminaries, but chiefly onto the Moon. Pliny the Elder, indeed, asserted this without determining it, in Book 2, chapter 97, saying: *That the tides of the sea come in and go back is most wonderful: in many ways indeed, but the cause lies in the Sun and the Moon*; nor does he explain the manner. But in Plutarch, Book 3 of *De placitis*, chapter 17: *Pytheas of Massilia: the approach of the sea comes about with the waxing of the Moon, and its recession with her waning.* This opinion has by far the most authors on its side; but the whole difficulty lies in the manner in which the Luminaries produce the varieties of the tide that we adduced at number 23 — the Moon especially, even when she lies hidden below the horizon, or is new and does not reflect the Sun's rays to the earth and the sea, or is within the Torrid zone and does not strike the waters of the temperate or frigid zones with perpendicular rays. Meanwhile, to the common opinion belongs that passage of Caesar, Book 4 of the *Commentaries*: [Margin: Caesar's opinion.] *On the same night it happened that there was a full Moon, which usually makes the greatest tides in the Ocean.*

[Margin: 12. The opinion of Contarenus and Faber.] XXXVI. The twelfth opinion, accordingly, has recourse to occult influences of the Luminaries, as do Contarenus [Gasparo Contarini] and Faber, and certain astrologers whom Picus censures in Book 3 *Against the Astrologers*, chapter 15 — on the ground that the Moon could not move the waters in this way when she is beneath the lowest part of the earth, since the light of the Moon, which is the vehicle of influences, cannot then reach them. But this opinion does not solve the question; it is just as if one said that the cause of the tide is unknown and hidden from us. [Margin: Refutation of the 12th opinion.] Cardinal Contarenus, moreover, adds that by this occult power of the Moon the waters of the sea are rarefied, and that, once they have been rarefied to the highest degree, they produce the tide. But it does not appear how the Moon, placed beneath the lowest part of the earth, could rarefy them — besides the other objections we shall shortly raise against this rarefaction.

[Margin: 13. Opinion.] XXXVII. The thirteenth opinion, closely akin to the ninth, holds that the Luminaries, and above all the Moon, produce the tide by heating and rarefying the waters and thinning them into vapours, but

not consuming them. [Margin: Of Contarenus, Aversa, Crescentius, Borrus, Rheita.] So hold Contarenus, Book 2 of *De elementis*; Raphael Auersa [Raffaele Aversa], tome 2 of the *Philosophia*, question 42, section 7; Crescentius, Book 3 of the *Nautica*; Hieronymus Borrus [Girolamo Borro], in his treatise on this subject, page 125; and most recently Antonius Maria de Rheita [Anton Maria Schyrleus de Rheita], in his *Radius Sidereomysticus*, Book 4, chapter 3. For they say that the Moon, as she ascends, gradually rarefies the waters until, as she comes to the meridian, they swell, rarefied to the highest degree; and that as she descends from the meridian, striking the waters with more oblique rays, she diminishes the rarefaction, and the waters, condensed, flow back more and more and return to their former state, or are resolved into vapours. But Galileo, in the fourth dialogue *On the System of the World*, Chiaramonti, Book 13 of *De universo*, chapter 22, and Franciscus Resta, tractate 1 *De mari*, chapter 14, prove that the waters of the sea are not rarefied by the Moon's heat during the tide. For if the water were rarer, it would also be lighter in the same bulk; some heat would be felt in it, and some smoke would appear, as in boiling water. But if an equal quantity of the same sea water, drawn before the tide and during the tide, is weighed, it is found to be of the same weight, and no sign of rarefaction or heat is detected in it, whether from density or from smoke. Nor do ships sink deeper during the tide than at other times, which would necessarily happen if the water were rarefied and became lighter. [Margin: Refutation of the 13th opinion.] Galileo adds that, if the tide were produced in this way, a violent heat would be necessary (which cannot come from the Moon), and so great that it would make the sea water unbearable from its heat to a finger dipped in it. Against this view Cabeo, Book 2 of the *Meteorologica*, text 6, question 6, adduces must, which, swelling violently, boils without unbearable heat; and, conversely, water heated long before, which nevertheless boils no more, because its subtler parts, rarefied in the first boiling, into bubbles have vanished, and these into the air. But granted that rarefaction is not ruled out on this head, it still remains to give the reason why the Moon, placed beneath the earth, can rarefy the waters more as she approaches the lowest meridian than when she is above the horizon and receding from the meridian; and why she can do more on more remote waters, such as those around Ireland, England, Holland and Belgium, where the tides are strongest, than on nearer ones, such as those from Gades as far as the Tropic of Cancer, where there is no perceptible tide; and why, likewise, she does more at new Moon than at the quadratures, in which she both pours more light onto the waters and comes nearer to them; and so of the other diversities adduced at number 23. To the first difficulty, however, Borrus and others answer, with Albumasar, Book 2 of the *Introduction*, that the rays of the Moon, when she is below the horizon, are reflected back onto the earth and water of our hemisphere by the opposite heaven. But these men suppose that the heaven is hard and fit for reflecting light; and besides, that light would be much fainter, and the flow would accordingly be almost three times smaller.

[Margin: 14. The opinion of Scotus, Io. a S. Thoma, Resta, Mastrius, and nearly that of Pliny.] XXXVIII. The fourteenth view has recourse to that power of the Moon by which she predominates over humours. For just as the humours of plants, of shellfish and of the other animals are stirred, and abound especially at full Moon, so the waters of the sea seem able to be stirred and to swell by the action of the Moon, and to grow not only through rarefaction but also through a new increase. So Scotus, on Book 2, distinction 14, question 3; Ioannes a S. Thoma [João Poinsot], as reported by Mastrius, disputation 4 *De caelo ac meteoris*, question 4, number 154; nor does it displease Mastrius himself; Resta acquiesces in it, tractate 1 *De mari*, chapter 14; and Pliny favours it, Book 2, chapter 99, where, after setting out the tide of the sea in chapters 97 and 98, he says: *From which a true conjecture arises, that the Moon is not without reason thought to be the star of breath; that it is this which saturates the earth, and as it approaches fills bodies, and as it departs empties them; that therefore shellfish grow with its increase, and that those creatures which have no blood feel its breath most*, etc.; and in chapter 101: *The Moon, a feminine and soft star, loosens moisture and draws it, does not carry it away.* Just as shellfish, then, abound in moisture — not because they feed more copiously at full Moon, as Vallesius [Francisco Vallés] would have it, chapter 71 of the *De sacra philosophia*, but because of the warmer nights and the heat that loosens congealed humours, as Aristotle teaches, Book 1 of *De partibus animalium*, chapter 5 — so tides occur when the thick humours are loosened. [Margin: The 14th opinion is refuted.] But against this account there militate the things we brought, toward the end of number 37, against opinion 13; and besides, all waters — of the sea, of rivers and of lakes — ought to undergo a tide, at least at full Moon, if indeed the Moon, by predominating over all moist bodies, can produce the swelling of moist things.

[Margin: 15. The opinion of Aristotle, Heraclitus, Thyaneus, Vallesius.] XXXIX. The fifteenth opinion [?] refers the cause of the tide to breaths and blasts beneath the waters and around the waters of the sea, stirred up by the Sun and by the Moon according to their varying disposition. Plutarch says, Book 3 of *De placitis*, chapter 17: *Aristotle and Heraclitus hold that this is produced by the Sun; for by its turning it carries round with it a great many blasts, and when these rush in and push the Atlantic forward, the Atlantic swells and makes the tide; and when they are at last lulled, it draws back, gathering in its tide, and this is the reciprocation.* Perhaps Thyaneus [Apollonius of Tyana] meant the same when he said that it is produced by spirits bursting out of the sea and stirred up around it; and so too Vallesius, chapter 52 of the *De sacra philosophia*, who refers the proximate cause of the tide to blasts shut up within the caverns of the earth, but the remote cause to the Moon and the Sun, which generate and stir those blasts. [Margin: The opinion of Trimarchus.] Trimarchus too, Book 2 of the *Meteorologica*, disputation 1, section 7, numbers 86 and 87, refers this motion to exhalations under the sea, like those under the earth at the time of earthquakes, which, once they have been rarefied by the heat of the Sun and the Moon, seek an exit and burst out with great force; sailors attest that when the tide comes

on, ships tremble, even in calm weather, as in an earthquake. These exhalations bursting out into blasts, he thinks, were infused into the sea by God from the beginning of the world, yet are preserved by the action of the stars; and, pressed by the mass of the sea, they are driven back into the caverns, and from this the ebb results. [Margin: The opinion of Bacon.] Indeed, before him Rogerius Baccon [Roger Bacon], in the *Letter to Clement V*, Supreme Pontiff, said that the light of the Moon stirs up vapours under the waters, which engorge the waters with bubbling swellings, vapours that it cannot consume; that fewer are stirred up by weaker rays, when she shines obliquely on the seas, and more by stronger and more direct rays, when she strikes them on the meridian; and that the same rays, while the Moon is beneath the lowest part of the earth, are reflected from the highest heaven, or from the eighth or ninth sphere, as being dense and bounding the sight. But he adds that the tide becomes more sluggish as the Moon nears the meridian, because of the vapours dissolved by the stronger rays; and for this he is censured by Io. Picus, Book 3 *Against the Astrologers*, chapter 15, on the ground that he speaks against the experience of a greater tide on the meridian.

[Margin: Cabeo's opinion.] Our own Cabeo, Book 2 of the *Meteorologica*, text 6, question 9, having taught that this motion does not arise from rarefaction or from a real increase of the water, nor from a local motion alone impressed by the Moon — since then the tide would occur everywhere and always toward the west — adds that in the Moon, besides heat and light, there are other active qualities, manifest to us in their effects though unnamed, from which come the catarrhs and very troublesome fluxes in lunatics at the time of the lunar syzygies, even if they live shut up in their rooms. Similarly, then, the tide arises not from a thinning of the water itself, but from a thinning, or ebullition, of spirits rising from the floor of the sea — not as though they boil from heat, but because they are moved by the Moon by a peculiar force, just as a swelling occurs in must without heat, and just as catarrhs are moved by the Moon. The spirits on the floor of the sea, moreover, are analogous to the spirits of saltpetre and sulphur, and so the tide occurs only in those waters in which there are spirits of this kind; nor do clouds, or the earth interposed between the Moon and our sea, stand in the way, just as the walls of houses do not prevent the Moon from stirring, by her peculiar power, the spirits or humours in our bodies and provoking fluxes or catarrhs. [Margin: Fournier's opinion.] Finally, our Fournier likewise, Book 9 of the *Hydrographia*, chapter 8, professes that the tide of the sea is a kind of secret and a very great mystery to be observed in the sea, but that its probable cause is a stirring, by the Moon, of the vapours and breaths enclosed in the sea water. For just as the causes of fevers can be reduced to two heads — namely, to the disposition of the humours of the human body and to the active power of an external agent — and the mass of humours, like a kind of leaven, is cooked by the force of the external agent, is inflated, putrefies and, percolated through the blood, is inflamed, so that from the diversity of the inflammable humours there arises a diverse species of fevers, and from that same

diversity, and also from the diverse power of acting of the external agent, the motions and periods of fevers are slowed or quickened: so the material cause of the sea's tide is hot vapours and breaths, which are in the soil and ground lying beneath the sea and are probably of the same nature as the rest of the earth from which metals are dug. For it is established that in digging these out, when the diggers have gone beyond 80 or 100 paces, though they always felt cold before, they soon meet so great a heat that they cannot bear it beyond three hours without danger and must withdraw from there; this has been reported above all by those who explored the mines of Hungary, whose depth is greater than 300 cubits. And although hot and viscous breaths and vapours of this kind come from the Sun, the Moon nevertheless has the power to stir them by her influxes; and, swelling them further, partly by her light and partly by her other influxes, she raises the seas and causes the tide, according to the disposition both of the vapours and breaths already mentioned and of the harbours, shores and coasts. From this, too, comes what Pliny said in Book 2, chapter 98: *All seas are purged at full Moon, some also at a fixed time. Around Messina and Mylae refuse like dung is cast out on the shore, from which comes the fable that the oxen of the Sun are stabled there.* Strabo had noted this earlier, in Book 1 of the *Geography*, saying: *When the sea belches, the shores give back a hoarse voice, so that the flood has a certain force such that it repels what is foreign. And indeed they call this a kind of purging of the sea, by which both corpses and the fragments of shipwrecks are carried out onto the land.* Finally, Fournier says that if anyone attentively considers the history of the sea's tide, he will find in it all the symptoms of fevers, and that the only difference lies in two points. [Margin: The tide of the sea [?] is its fever.] The first is that the Moon applies herself to stirring the sea more regularly than any external agent applies itself to the human body in provoking fevers; the second, that the human body, because of the greater compactness of its parts, cannot swell from fevers and alter its former shape. Had Pliny heard this, he would far more willingly have pronounced what he said in Book 2, chapter 97: *But these motions are detected about the shores more than in the deep, since in the body too it is the extremities that feel the pulse of the veins, that is, the breath, more.*

XL. The sixteenth opinion prefers to recognise in the Moon a certain magnetic power, by which, through loca- l motion, she attracts the waters to herself and entices them, until, by their own weight and because of the excessive heap, they fall back again and subside. [Margin: 16. Opinion: of the Conimbricenses, Zanardus, Scaliger.] Of this opinion seem to be the Conimbricenses, on Book 2 of the *Meteorologica*, tractate 8; Zanardus, question 30; and Scaliger, Exercise 52. Scaliger, having said of the tide of the sea, on the authority of many authors, *Since it had been observed to follow the course of the Moon, they judged the Moon to be its author*, and having at once objected, *But the Moon does not touch the waters*, at once solves the objection, saying: *This gave trouble to some of the Peripatetics, to whom the magnet too ought to have given it. If that motion is produced in iron by the stone without contact, why will the sea not follow the body of the noblest star?* And towards the end of that exercise: *I would dare to affirm that there is then no*

new generation of waters — namely, when the tide occurs; *with what purpose I should profess rarefaction, I truly do not know. But that they are lifted up at that time, like iron by the magnet, every month, in all places except that one shore alone, has been found by continual observations.* He speaks chiefly of the full Moons, at which, however, the increases of the sea at the coasts of the Indus are smaller than at the new Moons. [Margin: Gilbert's.] William Gilbert tacitly insinuates this very thing, Book 6 of *De magnete*, chapter 6, when he attributes to both the Moon and the Earth a magnetic power for attracting and leading round kindred bodies. [Margin: Kepler's.] But most lucidly of all Kepler, in the Introduction to the *Commentaries on Mars*, whose opinion we shall set out only in his own very words, distributed into several propositions, which are as follows.

[Margin: Kepler's theses [?] on the tide of the sea.] 1. *If the Moon and the Earth were not held, each in its own circuit, by an animal force or some other equivalent one, the Earth would ascend to the Moon by a fifty-fourth part of the interval, and the Moon would descend to the Earth by about fifty-three parts of the interval, and there they would be joined — supposing, however, that the substance of both is of one and the same density.*

2. *If the Earth ceased to attract its waters to itself, all the waters of the sea would be lifted up and would flow into the body of the Moon.*
3. *The orb of the attractive power that is in the Moon is stretched out as far as the earth, and entices the waters under the Torrid zone — to meet it, that is, wherever it falls on the zenith of a place: imperceptibly in enclosed seas, but perceptibly where the beds of the Ocean are widest and the waters have ample freedom of reciprocation. When this happens, the shores of the lateral zones and climates are laid bare, and any shores, even under the Torrid zone, formed by the more recessed bays of the neighbouring Ocean. And so, as the waters rise in the wider bed of the Ocean, it can happen that in its narrower bays — provided they are not too tightly enclosed — the waters even seem to flee from the Moon when she is present: for they subside, their supply of waters having been drawn off outside.*
4. *But since the Moon flies swiftly across the zenith, and the waters cannot follow so swiftly, a flow of the Ocean does indeed occur under the Torrid zone towards the west, until it strikes the opposite shores and is bent back by them; but at the Moon's departure the gathering of the waters, or the army that is on the march towards the Torrid zone, is dissolved, as being deserted by the traction that had called it forth; and, having gained an impetus, it returns, as in vessels of water, leaps against its own shores and covers them; and this impetus, during the Moon's absence, begets another impetus, until the Moon, returning, takes up the reins of this impetus, moderates it, and leads it round together with her own motion. Thus all shores equally open are filled at the same hours; the more recessed ones later, and some in different ways because of the differing approaches of the Ocean.*

Yet the same Kepler, in the *Epitome of Copernican Astronomy*, Book 1, page 128, adds as an auxiliary cause of the tide the natural inertia of the waters, which

hang back in the west while the earth withdraws itself towards the east; and from this, he says, comes a flow of the waters that makes navigation towards the west easier, which, however, is not felt on the shores of America towards the east, because of the vast length of the Ocean, which strikes no obstacle.

[Margin: Refutation of the [?]6th opinion.] But how many things are asserted here, how many concealed, against the testimony of history? For how false it is that the tide occurs primarily and of itself from east to west, when several tides occur from north to south and the reverse. Moreover, if the Moon enticed the waters by a magnetic force and by local motion alone, she would certainly entice those that are nearer to her, or would entice all of them most when she herself came nearest to them. But the opposite happens: for the greater tides occur at the English, Dutch and Belgian shores, whose waters are farther from the Moon than in many parts of the Torrid zone; and when the Moon, at the quadratures, descends towards the earth, the tides are nevertheless the smallest. Again, if in more recessed seas the tides are smaller than in more open ones, why is the tide not greater in the Tyrrhenian than in the Adriatic, especially in places set under the same meridian? Finally, there are many other features, recounted by us at number 23, whose cause does not appear in this magnetic power.

[Margin: 17. Opinion. Of Seleucus. And of Galileo.] XLI. The seventeenth opinion ascribes this motion of the sea to the motion of the Earth, diurnal and annual together. This was devised long ago by one Seleucus, whoever he was, of whom Plutarch speaks thus expressly, Book 3 of *De placitis philosophorum*, chapter 17: *Seleucus the mathematician, who himself also moves the Earth, says that the turning of the Moon runs counter to the Earth's revolution and motion; and that, as by this impetus the breath gathers itself between these two bodies and rushes into the Atlantic, the sea, with probable reason, is thrown into disturbance.* But Galileo, though passing over Seleucus's name in silence through forgetfulness, criticises his opinion in the fourth dialogue *On the System of the World*, Latin page 343, on the ground that the Moon's motion is not contrary to the Earth's motion, since it is directed towards the same quarter. And so Galileo himself explained the tide of the sea in another way, through the unequal motion of the Earth, as we have already related from number 1 to number 10. We shall shortly show this to be most evidently false, from number 43 on.

[Margin: 18. Our opinion.] XLII. The eighteenth — our own opinion, gathered and selected from many of the preceding — is that the tide of the sea is likewise produced by the Moon, which stirs the humours, vapours and breaths on the floor of the sea, and moves them without perceptible rarefaction at the surface of the sea, according to their diversity, as opinions 14 and 15 hold; yet in such a way that to its variety there concur not only the Sun and the other positions of the stars, but also the inrush of rivers nearer to the tidal places, as opinion 1 holds; and the twofold course of the sea, of which we spoke from number 11 to 15, as opinion 3 holds; and the whirlpools of waters vomiting out the waters from subterranean chasms and sucking them back again, as opinion

2 holds; and the differing situations of the basins and shores, as opinion 4 holds; and at times winds, as opinion 8 holds; and subterranean fires, as opinion 9 holds. Yet even when all these are fused into one, the effects we enumerated at number 23 will always be worthy of wonder, and especially the one seen in the daily period of the tide that returns when the Moon, below the horizon, approaches the lowest part of the meridian. For I am not yet persuaded that the Moon transmits her power through the whole terrestrial globe, and that it is not at all blunted or weakened; or that it reaches as far as the opposite part of the highest heaven, from which it would be reflected to us after twice traversing an immense space (since we hold that the other heavens are by no means solid). Nor can we explain this daily vicissitude through the Moon's monthly libration and the varying emergences or concealments of her spots at the edges. Nor have I so far found anyone who satisfies me on this point; and I am not ashamed not to know it, since I do not doubt that I am ignorant of many other things easier to know. [Margin: The final cause of the sea's tide.] The final cause of these motions Franciscus Resta touched on briefly and readily, following Bodinus [Jean Bodin], Book 3 of the *Meteorologia*, tractate 1, chapter 15. For the tide of the sea serves now for washing away and keeping off its filth, now for fisheries, now for the more convenient arrival of ships for bringing in and carrying out goods, now for salt-pans, the natural workshops for making salt, now for stirring up many animals; and I add, for supplying abundant matter for the praises of God the Creator and for acknowledging the weakness of our wit. Now to Galileo, who imposed on us the necessity of so lengthy a treatment, lest we should seem to wish to demolish with a light arm an argument that he himself judged to be of such weight for the motion of the Earth.

Refutatio Cauſæ Diurni Aeſtus à Galilæo adductæ.

Refutation of the cause of the daily tide adduced by Galileo.

XLIII. Here we must go over again the doctrine of Galileo set out from number 4 to 7, together with the diagram given in the same place. For he said that the cause of the daily flow and ebb, which returns every twelve hours, is the unequal diurnal motion of the Earth HKFG about its own centre B, towards the eastern quarter, from H to K; that this motion is faster in the upper semicircle GHK, because it assists the motion of the centre B, carried by the force of the annual motion towards the same quarter, from B to C; but that in the lower semicircle KFG the Earth's motion is slower, since it strives against the annual motion of the centre B; and that therefore there occurs alterna- tely the flow and the ebb, and the other things we described there. But against this cause there are very many arguments, partly of others, partly our own; and the first, that of Chiaramonti, which strikes directly at Galileo's foundation, must be set out, although in truth it is invalid.

Diagram. Galileo's figure for the tide, set in the left column. A small circle about the centre B carries the points H (top), K (left), G (right) and F (bottom). A larger circle passes above it through O, and a long arc runs from P on the left through O to Q at the right. Below, a large circle about A carries C (left), E (right) and D (bottom), with M and N inside it on either side of A and an inner arc running from M up towards L and down to N. Two small crescent Moon signs are drawn, one on the arc just below O and one beside L.

- O (top, on the upper arc): O
- H, K, G, F (on the small circle about B): H, K, G, F
- B (centre of the small circle): B
- P (left end of the upper arc): P
- sign at the right end of the upper arc: a loop with a curled tail resembling the sign of Leo [?]
- L (below F): L
- A (centre of the large circle): A
- M, N (inside the large circle): M, N
- C, E, D (on the large circle, left, right, bottom): C, E, D

[Margin: 1. Argument against Galileo, from Chiaramonti and Cabeo, but invalid.] *First.* Scipione Chiaramonti, in his Italian defence of the *Antitycho*, part 4, chapter 25, charges Galileo with a truly shameful equivocation: Galileo transfers properties that presuppose a true and real inequality of motion to an inequality that is merely apparent. For the inequality of the Earth's diurnal motion (this motion being granted meanwhile for the sake of argument) is not real, says Chiaramonti, but optical, and merely apparent to an eye imagined to be at A. The parts GHK will appear faster beneath the Firmament, because the centre B of the circle GHKF is carried forward in the same direction, as if it were the centre of an epicycle; but the parts KFG will appear retrograde a little below the points K and G, because their motion is contrary to the motion of the centre B. It is by this reasoning that Galileo himself tried to show that the retrogradation of the planets is not real but apparent. Add that for us, who are not at A but on the surface GHKF, on which we watch the motion of the sea, the motion of the Earth not only is not unequal — since Galileo admits that in reality it is equal in itself — but cannot even appear unequal: both because we are turned in the same way with the Earth, and because we cannot observe by any sense even any motion of it at all, let alone its inequality. But if we were at the centre B, the motion of the Earth would appear equal to us.

[Margin: Galileo's argument in form.] Now Galileo's argument, reduced to form, ran like this: *In every vessel full of water and moved now more slowly, now more quickly, the water flows now to one edge, now to the other edge. But the Earth is a vessel of this kind; therefore, etc.* To this argument Chiaramonti grants the major premise as regards real speed and slowness, and denies it as regards merely apparent; the minor premise, by which the Earth is supposed to move more slowly and more quickly, he denies as regards real speed and slowness, and grants as regards apparent speed, for an eye imagined at A. Cabeo touched

on something similar, somewhat obscurely, in Book 2 of the *Meteorologica*, text 6, at the end of question 8. But both are mistaken. For not only for an eye at A, but for one placed anywhere, the point H of the Earth, in the space of the world, through the motion compounded of the diurnal motion about the centre B and the annual motion of the centre B about the centre A, would have completed a much longer path than if it had been moved by the diurnal motion alone about the centre B. So much so that, according to what was said with Kepler in chapter 6, number 2, such a point on the Equator would complete in one hour 240 German miles by the diurnal motion, but 740 by the force of the annual motion, that is, 980 miles by the compounded motions; whereas the point F would complete 500 miles in one hour.

[Margin: 2. Argument against Galileo.] *Second.* Galileo contradicts both himself and Copernicus, since he attributes to the water a motion different from, and sometimes contrary to, the motion of the Earth, and yet attributes its origin to the diurnal and annual turning of the Earth itself, and not to anything else. I too noted this inconsistency long ago, and I have seen it remarked by Chiaramonti in the defence of the *Antitycho*, part 4, chapter 25, and by our Fournier, Book 9 of the *Hydrographia*, chapter 15. For Copernicus, raising against himself in Book 1 of the *De revolutionibus*, chapter 7, the objection why heavy bodies thrown straight upward fall back onto the same point of the Earth, although that point has meanwhile been carried away from under them with such speed, and why the clouds themselves, and whatever else hangs in the air, do not appear always to be carried to the west if we are rolled with the Earth towards the east, replies in chapter 8 with these words: *What then should we say of the clouds and the other things hanging in the air in any way, or sinking down, or again tending upward? Only that not only the Earth with the watery element joined to it moves in this way, but also no small part of the air, and whatever things have a kinship with the Earth in the same way. Either because the neighbouring air, mixed with earthy or watery matter, follows the same nature as the Earth; or because the motion of the air is acquired, a motion it shares from the Earth through contiguity, in perpetual revolution and without resistance.* Galileo accepts this doctrine in Dialogue 2 on the System of the World. Therefore, if not only watery bodies but also the clouds and things like them, which are near the Earth and yet cohere with it less, are moved with the same speed and kind of motion as the Earth towards the east, then the whole water of any sea must likewise be moved equally with the Earth's globe in the same direction, if this common motion is considered; nor could it be moved elsewhere, or unequally, except by some particular motion from outside, for instance by winds. Therefore, when Galileo attributes to the sea a motion of flow and ebb different from the diurnal turning of the Earth, on the ground that water is fluid and does not wholly obey that motion — which the air near the Earth, though much more fluid, does obey — he contradicts both Copernicus and himself.

[Margin: 3. Argument.] *Third.* If the diurnal motion of the Earth together with the annual could produce the flow and ebb of the sea, it would have to

produce it through a sudden change of motion and an abrupt passage from speed to slowness, or from slowness to speed, as is evident in a vessel full of water: for unless the water is shaken by a sudden change, it does not perceptibly surge, nor is it raised now to one edge, now to the other. But even if the Earth is admitted to move unequally, the change from speed to slowness still does not happen all at once, in a single impulse, nor immediately, but gradually and by degrees, without being felt, about the points K and G, exactly as in planets moved on an epicycle. I afterwards found this argument in Cabeo, Book 2 of the *Meteorologica*, text 6, question 8. Indeed, this inequality is itself imperceptible, especially far from the points F and H, as we shall show in chapter 19, from numbers 9 and 11.

[Margin: 4. Argument.] *Fourth.* From the account of the daily tide of the sea given from number 17, and from the nautical rules for determining the hour of the highest tide, or high water, given from numbers 20, 21 and 22, it is evident that the tide of the sea has a very great connection with the Moon's motion, both daily and monthly. It is evident, too, that in the same places where it occurs, the tide is postponed each day by about 48 minutes — that is, by as many minutes as the Moon rises later each day because of its proper motion — and that the highest tide occurs as the Moon approaches the meridian above or below the horizon, even outside midday or midnight. Sailors gathered these rules from long observation and very certain experiments, since ignorance of them would have been very dangerous to them. But if the tide of the sea depended on the motion of the Earth, and took its vicissitudes and laws from it, the rules already mentioned would be vain and most deceptive: for no cause can be drawn from the motion of the Earth why the highest tide of the whole day or night should occur as the Moon approaches the meridian, or why it should be delayed each day by 48^{m} of time [minuta horaria]. And so Galileo, in that Dialogue 4, as if in jest, not to say contempt, belittles the opinion of those who ascribe the tide of the sea to the Moon; and he either shows himself ignorant of nautical matters, or cunningly conceals their rules. But he could not deceive the experts, nor will he ever be able to persuade sailors to take the rules of the tides from this feigned motion of the Earth, uncertain and imperceptible as it is, and to abandon those which they obtained from the motion of the Moon, with such agreement among practitioners and such success in navigation.

[Margin: 5. Argument.] *Fifth.* If the flow and ebb of the sea came from the diurnal whirling of the Earth towards the east, but unequal in the way Galileo imagines, it would have to be universal for every sea extended along the longitude of the Earth from west to east, and be felt alternately on every eastern and western shore. And thus the coast of Africa, which runs from the western mouth of the Strait of Cádiz [Strait of Gibraltar] as far as the Tropic of Cancer, and is free of tide, would have to experience a tide when the waters returned from the eastern coast of America; or the western coast of Spain would feel a tide as the waters came back from the coast of Syria, at least during those 8 hours in which the people of Cádiz have observed the waters of the Mediterranean

flowing out through that strait into the Ocean. I say this because Galileo says that no tide occurs on the eastern coast of Spain, on the ground that the waters of the Ocean, entering through the Strait of Cádiz, resist the waters of the Mediterranean carried towards Spain; which is not true of the whole day, but at most of 15 or 16 hours.

[Margin: 6. Argument.] *Sixth.* If the tide of the sea came from the diurnal turning of the Earth, as Galileo holds, then on those shores which face towards the eastern or the western quarter, and at the same time lie under very nearly the same meridian, the tide would occur in the same way, at the same hour and with the same measure, without perceptible difference. But this conflicts with daily experience and with the account of the tide already given: for if anyone considers the tides that occur on the coasts of England, the Low Countries, France, Portugal and Guinea, he will find a very marked difference both in the time and in the measure of the tides. Moreover, it would have to be that at the time when the sea is high on one eastern shore, it is low on the western shore opposite it, which is likewise against the account of the sea's tide; and much less could the waters of two seas, meeting each other in the same stretch of sea, cause a tide; rather, at the same time both would run towards the east, or both towards the west. But it happens otherwise in the Strait of Magellan: there the waters rushing in from the Atlantic Ocean on one side and from the Pacific Sea on the other, and meeting each other, produce a notable tide in the middle of that strait, and afterwards, subsiding, flow back, the one into the Atlantic, the other into the Pacific.

[Margin: [?]. Argument.] *Seventh.* If the sole cause of the sea's tide were the inequality of the Earth's motion towards the east, then certainly no perceptible or great tide could occur on shores and in ports situated towards the north or the south; and that is why Galileo, from either ignorance or cunning, denied that a tide occurs in the Red Sea. But the account of the sea's tide shows, by very many plain experiments, that this is false. For a tide occurs not only in the Red Sea, but also on the southern coasts of America beyond the Gulf of Mexico, and likewise on the southern coast of the East Indies from Calicut to Cambodia, where it is so rapid and violent that in two hours it covers at least 15 miles of shore, and in as many hours, flowing back, lays the same shore bare; it drives the waters of the river Indus back upstream towards their source, and then, flowing back, leaves ships high and dry. And if the English, the Dutch and others who sail every year to Spitsbergen to take whales, as far as the 80th degree of polar altitude, are asked, they will testify that the waves of the tidal Ocean roll down and rush from south to north, and indeed more violently than happens anywhere from east to west, or from west to east. So too in the Archipelago of St Lazarus the tide is carried every day towards the south with such force that it breaks ropes 27 fingers thick, as Fournier relates in Book 9 of the *Hydrographia*, chapter 16; he uses this very argument against Galileo, as does Cabeo, Book 2 of the *Meteorologica*, text 6, question 8.

[Margin: 8. Argument.] *Eighth.* The continuous motion of the Earth towards the east, so rapid that in 24 hours it would turn the whole globe of the Earth with the waters enclosed in it, would hinder not only the tides strictly so called, which occur through the motion of the sea towards the poles or the Equator, but also the other flows of the sea running towards the north or towards the south: for it would at length overcome their motion and roll them along together with itself. But it is established that the waters of the sea run from the north or from the south towards the Equator, as is clear from the account given at number 12. Moreover, there would be hindered both the tide, or flow and ebb, of the Euripus of Chalcis, and that of the currents between Africa and the island of St Lawrence, and the course of the ice rushing down from the north, of which we spoke at the same number 12.

[Margin: [?]. Argument.] *Ninth.* In the preceding figure Galileo supposes the motion of the Earth to be slower in the lower semicircle KFG, which is lit by the Sun, and faster in the nocturnal semicircle GHK. So if the tide arose from the motion of the Earth, the sea would have to flow everywhere for about 12 hours each day and ebb for as many; and of the two effects of this motion, one would be felt in places moving from K through F to G, the other in places moving from G through H to K, in perpetual succession. Yet observation is against this motion.

[Margin: 10. Argument.] *Tenth.* If the tide of the sea, properly and strictly so called, is rightly considered, it is not a mere local motion, but a kind of swelling upward from the very floor of the sea — granted that the waters, swelling in this way, then run towards the lower parts of the sea or of the shores. But if it came from the motion of the Earth, it would be a mere flowing in and flowing back, by local motion, of waters going and returning this way and that.

[Margin: 11. Argument.] *Eleventh.* If the motion of the Earth towards the east, by its inequality, were the sole cause of the sea's tide, then everywhere the variation arising from the passage from speed to slowness would always be observed at sunrise, and that arising from slowness to speed at sunset; and the variation arising from the greatest slowness would be observed at midday, while that arising from the greatest speed would be observed at midnight. For in the preceding figure set out by Galileo, the passage from the fast motion of the Earth to the slow occurs at the point K of the terrestrial Equator, and similarly on its parallels, where the Sun A begins to be seen; and the passage from the slower motion to the faster occurs about the point G, where the Sun ceases to be seen and appears to set; while the greatest slowness occurs at the point F, for which the Sun A makes midday, and the greatest speed at the point H, where it is midnight. But no experiment supports this observation; rather, almost the whole account of the sea's tide opposes it. For its variations, as to the beginning and end of the tide, or as to its greatest or least measure, do not depend on the four cardinal points of the day, but on the Moon's elevation above the horizon and her descent, and on her approach to the top or the bottom of the meridian.

[Margin: 12. Argument against Galileo.] *Twelfth.* Suppose the flow and ebb of the sea arose from the Earth's diurnal whirling in 24 hours. Since in each hour 15 degrees of the terrestrial Equator and of each of its parallels revolve towards the east, then, for this motion to be proportioned to the impetus of the Earth driving the waters, the waters running from west to east would have to reach from the eastern shore of a western region to the opposite shore in about as much time as the degrees of longitude intercepted between the western and the eastern shore require: namely after about one hour if they were 15 degrees apart, after two if 30 degrees, and so on. And so from the coast of Spain the waves would at some time have to reach the coast of Syria in 3⅔ hours, since the two are about 55 degrees apart in longitude; and from the coast of North America, in the land of Florida, to the western coast of Spain — just as from the coast of New France to the western coast of France — they would at some time take the same amount of time, since these too are about 55 degrees apart in longitude: at some time, I say, namely when, because of the inequality of the diurnal motion that Galileo asserts, they struck the shores of the western land and from there turned back eastward to the opposite shores on the same parallel. And from the eastern coast of England to the western coast of Denmark or Norway, which are six or seven degrees of longitude apart, the waves would flow within 24^{m} or 28^{m} of time. But three absurdities would follow from this, that is, three effects that conflict with nautical experience. First, ships sailing eastward on parallels of this kind would experience an incredible speed of their own accord, even when the winds did not oppose them, and such as they have never experienced. For on the parallel of latitude 30°, along which one generally sails from Spain to Syria, each degree contains 61⅕ Italian miles, of which, according to what was said in Book 2, chapter 7, one degree on the Equator contains 72¼. Therefore, if in each hour the water of the sea carrying a ship completed 15 degrees, that ship would certainly run through 918 Italian miles in one hour, [Margin: The greatest speed of ships.] and in latitude 45° it would complete 756 miles in one hour; whereas, even on the fastest course, it barely completes 500 miles in a whole day in the Mediterranean, and 200 in the Ocean, as I said in Book 2, chapter 16, number 8. *Second*, ships meeting on a contrary course the waves flowing back from west to east would meanwhile experience an incredible and insuperable resistance; and yet it is certain that those sailing westward are perpetually helped by the course of the sea towards the west, as we showed at number 13. *Third*, it would follow that in that stretch of sea which lies between England and Denmark or Norway the waves would flow within 24^{m} or 28^{m} of time, and flow back as often to the opposite shores; and so there would be 24 tides a day and as many ebbs — which has not so far been detected, not only there, but not even in any Euripus.

[Margin: 13. Argument.] *Thirteenth.* From Galileo's opinion — admitted, though with little consistency as regards the motion of the Earth, yet as a hypothesis — it would follow that no perceptible tide occurs in seas or gulfs that are rather narrow along their length and enclosed within neighbouring

shores, especially those facing north and south. Of this kind are not only the Red Sea, of which we spoke above, but also the sea between England, Norway, Denmark and the Low Countries; our Adriatic Sea, which is narrower than the Tyrrhenian, or Gulf of Venice; the Persian Gulf; the Bay of Bengal; and the Gulf of China. And yet notable tides occur in them, so much so that between England and the Low Countries they rise 50 and 70 feet on the one side and 15 and 20 on the other, as our Fournier often observed and related in Book 9 of the *Hydrographia*, chapter 20. But reread the account of the sea's tide, where the tides of gulfs and straits are discussed.

Refutatur Cauſa varietatis Menſtruæ & Annuæ marini Aeſtus à Galilæo ficta.

The cause of the monthly and annual variation of the sea's tide devised by Galileo is refuted.

XLIV. Recall what I said at number 7. Galileo holds that the diurnal motion of the Earth and of the lunar heaven, taken together, is slower at new moons, because the Moon must then describe in the same time a greater arc of the annual orb, but faster at full moons, because it describes a smaller arc. And from what was said at numbers 8 and 9, on Galileo's hypothesis the diurnal motion adds more to the annual motion at the solstices than at the equinoxes. In this way he tries to defend the monthly and annual variations that occur in the sea's tide, which, however, he did not set out definitely — I believe lest a candid exposition of them should harm his hypothesis. But against Galileo's hypothesis there are the following arguments, taken in great part from Cabeo, Book 2 of the *Meteorologica*, text 6, questions 9 and 10, and from Fournier, Book 9 of the *Hydrographia*, chapter 19.

[Margin: 1. Argument against Galileo.] *First.* If at new moons the diurnal motion of the Earth turns out faster than at full moons, and this difference is so great that it produces a perceptible difference in the sea's tide, then this difference would long ago have been observed in the diurnal motion of the Sun, for which Galileo and all the Copernicans substitute the motion of the Earth — and the more easily, the more often this happens within the year, that is, at least twelve times at new moons and twelve times at full moons. But neither Copernicus nor Tycho nor any other astronomer observed this difference, though they observed other differences of the celestial motions that are subtler, and that grow large only with time.

[Margin: 2. Argument.] *Second.* For the Moon to be faster at new moon and slower at full moon, it would not be necessary for the Earth itself to move faster or more slowly at that time. The Earth's customary motion would suffice, together with the varying distance of the Moon from the centre of the annual orb: brought nearer to it, the Moon would be faster at ☌ [conjunction]; brought further away, it would appear slower at ☍ [opposition].

[Margin: 3. Principal argument.] *Third, and principally.* From Galileo's hypothesis it would follow that greater tides occur at new moons, since the Earth is then quickened in its diurnal motion and the waters consequently surge more; and greater also at the quadratures than at full moons, and indeed on the very days of new moon. But we have already shown at number 18, from the account of the sea's tide, that the contrary happens. For in most places the tide is greater, or not less, at full moons than at new moons; nowhere, however, is it greater at the quadratures than at full moons; and in many places the highest increases of the tides do not occur on the very day of new or full moon, but one or two or even three days after, as we said there.

[Margin: 4. Argument.] *Fourth.* Suppose it follows — because the diurnal motion of the Earth is fastest at the solstices, as Cabeo, though rather timidly, gathers from Galileo's doctrine set out at numbers 8 and 9, since the diurnal motion conspires most with the annual and adds as much as the whole diameter of the Earth requires — that the tide is greater at the solstices than at the equinoxes, and greatest of all at solstitial new moons, as the same Cabeo gathers. But this is contrary to experience and to the account given at number 19. If, on the other hand, as Fournier gathers from it, the tide is smaller at the solstices than at the equinoxes, it would follow that the tide occurring at a solstitial full moon grows each day towards the quadrature, the further one moves from the solstitial day; and conversely that tides occurring at equinoctial quadratures are greater than tides occurring at solstitial new or full moons. But experience establishes that both are false, and that tides occurring at the solstices, whether the Moon is new or full, are far greater than those occurring at the quadratures, as was said at number 18.

To anyone, then, who rightly considers this whole hypothesis of Galileo, it will be clear that for the most part it not only does not explain the cause of the sea's tide, but even destroys the effect itself, and utterly overturns almost the whole account of the tide handed down by the most expert sailors. Now, therefore, to sail out of this tide, let us dissolve Galileo's argument, reduced to form.

[Margin: Galileo's argument in syllogistic form.] XLV. *That hypothesis is to be rejected by which no account of the tide of the sea can be given, and that one, on the contrary, is to be embraced by which it can. But by the hypothesis of the immobile Earth no account of the tide of the sea can be given; and by the hypothesis of the Earth moved with a diurnal and an annual motion it can. Therefore the hypothesis of the immobile Earth is to be rejected, and the hypothesis of the Earth moved with a diurnal and an annual motion is to be embraced.* [Margin: Proof of the major premise.] The MAJOR premise does not seem to need calling into question. For even if other things were unequal, and by the hypothesis of the Earth at rest an account were given equally well or better of some motions, at least the elemental ones, still the variety of the sea's tide is so great, and the question of the sea's tide is so celebrated and of such moment, that if it can at last be settled by some hypothesis, and a sufficient and highly probable cause can be adduced of all, or

of the principal, effects and accidents that appear in that motion, there is no reason why that hypothesis should not be preferred to one which can exhibit no sufficient cause of them. The first part of the MINOR premise, which is negative, is proved from Galileo's statements scattered here and there, indicated from number 3 to 10; and from the refutations and difficulties against all the opinions on the cause of the sea's tide that suppose the Earth unmoved, or do not count its motion among the causes, which we ourselves adduced from number 23 to 42. The second part is clear from Galileo's doctrine, explained from number 2 to 10.

[Margin: 1. Reply [?].] I reply, *first*, by granting the major premise and denying the minor as to both its parts. As to the first part: because without the motion of the Earth, through the 18th opinion presented at number 42, an account is given — not indeed evident as to all the effects of the sea's tide, but evident as to some and probable as to others. And where that account falls short, it falls short at the point on which Galileo, by the hypothesis of the moving Earth, has given no account at all: namely, why the tide occurs in just the same way when the Moon is placed below the horizon as when the Moon is above the horizon. For Galileo recognizes no necessary connection between the daily tide and the motion and position of the Moon, nor does he adduce from the motion of the Earth a particular cause for this particular effect, just as he does not for many other effects either. Therefore, although by the hypothesis of the Earth at rest the account given of the sea's tides is not absolute and wholly satisfying to our mind, yet, compared with the accounts which Galileo tried to beg from the hypothesis of the moving Earth, it is rendered much more probable, agreeing with very many effects and conflicting with none.

The second part of the minor premise, however, is denied because of the twelve arguments made against Galileo at number 43 and the four at number 44. From these it is clearly established that Galileo, in very many respects, conflicts with the most manifest experiments and observations about the sea's tide, made from the time of the Phoenicians to our own times; and, as our Fournier rightly said in Book 9, chapter 16 of his most learned *Hydrographia*, that he investigated the cause of a thing that does not exist at all in the nature of things — that is, the cause of a certain chimerical tide, devised by himself, but not of the tide such as it really is, and such as it has long been observed to be by those skilled in maritime matters.

[Margin: 2. Reply [?].] It is replied, *second*, by turning very many of the arguments set out at numbers 43 and 44 back against Galileo, saying: If the Earth moved, and by its motion were the efficient cause of the sea's tide in the way Galileo explains, the sea's tide would not be such as it really is; therefore either the Earth does not move, or by its motion it is not the cause of the sea's tide in the way Galileo explains.

CAPVT XV.

Chapter 15.

The system of Signor Giovanni Battista Baliani is set out, for explaining the cause of the sea's tides through the motion of the Earth better than Galileo managed — not asserted, but devised as a mere hypothesis.

I. I am indeed convinced that the Most Illustrious Signor Giovanni Battista Baliani, a patrician of Genoa, will not be unwilling if I publish the letter he wrote to me. It contains nothing secret that may not be revealed, and it takes nothing away from the esteem he long ago won among prudent judges of these matters by his most learned books on the natural motion of heavy bodies, solid and liquid. Indeed, the letter that follows will show his singular piety and prudence joined to keenness of mind, since he pays the Sacred Congregation of Cardinals such reverence, as is fitting, in this matter of the Earth's motion. His letter to me, faithfully rendered into Latin, runs as follows.

[Margin: Signor Baliani's letter to the author of this Almagest.]

Some time ago Signor Hieronymus Bardius showed me a letter of Your Paternity's, in which you express a wish to see my system, in which the Earth would revolve around the Moon. I replied that I do not deny that this conception once came into my mind, or my fancy. I came close to writing to Your Paternity about it, but refrained, because I gave this figment no assent and did not think it true, for many reasons, but chiefly because I believed it to be contrary to the decrees of those who hold the authority to judge matters pertaining to the Faith. But when I was very recently in conversation with Father Niccolò Cabeo (who, to my great sorrow, departed this life not long ago), and he warmly recommended Your Paternity's Almagest to me, the occasion arose for me to write these few lines to Your Paternity: to ask that you kindly let me know when the New Almagest may be hoped to come to light, and at the same time to give the reason for which I once conceived the system already mentioned, of the Earth around the Moon. It arose from my having seen that Galileo thought it could be demonstrated that the Sun is the centre of the flux and reflux of the sea — in which he plainly erred, as I wrote to him at once, after he had sent me his book. On that occasion I found that a true cause of the sea's tide would emerge if the Earth revolved around the Moon. I did not, however, assent absolutely to this hypothesis, for the reason already mentioned, and also because I do not yet see how the Moon could be placed at the centre of the universe, or how, with the Sun placed at this centre and the Moon set at the centre of the Earth's epicycle (which are the two ways of defending the sea's tide), all the celestial phenomena could be saved. So I wished to tell Your Paternity this slight foundation for the report made to you that I had it in mind to publish such a system. And finally I reverently kiss your hands. Given at Genoa, 1650 July 9.

Your Very Reverend Paternity's
Most devoted servant
Giovanni Battista Baliani.

II. When I had answered this most courteous letter that it seemed to me very difficult to uphold all the celestial phenomena by the system already mentioned without multiplying the motions in the Moon, he did not hesitate to write back to me this second letter.

[Margin: Another letter of the same man to the same.]

What Your Paternity told me in your most courteous letter about the publication of the Almagest would have been far more welcome had it offered me hope of a much earlier edition of that work. I pray nonetheless for Your Paternity's life and the very best of health, so that you may complete so great a work for the use and learning of men of letters. I then considered what Your Paternity wrote to me about that system of mine. And although I persist in believing that the Earth is in fact at the centre of the universe, I am still not persuaded that, if the Sun were placed there and the Earth turned around the Moon, it would be necessary to ascribe to the Moon other motions besides those that Copernicus conceived and those that he himself followed. For at first sight it seems to me that the appearances can be defended without new motions of the Moon around the Earth — at least none worth considering; but that one would nevertheless have to suppose the Great Orb much larger, and assume the Sun's distance far greater, and so also the distance of the fixed stars much longer, than even the Copernicans themselves reckon. I do not doubt that this would be a great paradox. Notwithstanding this, it seems to me that if GOD had willed to found such a system, it would answer to the experiments both of the celestial motions and of the sea's tide. May Your Paternity hold me excused if I importunately press these tiresome propositions, full of tedium, upon you, and may you deign to command me in something on your own account. Genoa, 1650 July 30.

Your Very Reverend Paternity's
Most obliged servant
Giovanni Battista Baliani.

III. This is what I had to point out to my reader about the system already mentioned — not so much to add the judgement of so great a man against Galileo, as so that others may learn from his example: if the conceptions of their own minds happen to be by no means in agreement with the authority of Holy Scripture or of the sanctions of the Church, then either not to give birth to them, but to suppress them by a pious and prudent, and therefore fruitful, miscarriage; or, if they happen to have given birth, to confine them within the swaddling-bands and cradle of mere hypothesis.

CAPVT XVI.

Chapter 16.

Toward a better understanding and solution of the argument for the diurnal and annual motion of the Earth together, drawn from the increase in the speed of heavy bodies, select theorems and problems on the speed of heavy and light bodies and on the increase of speed are put forward, drawn from our own experiments both in air and in water.

CAPVT XVI.

I. For twenty centuries and more there has flourished in the academies of the natural philosophers, especially the Peripatetics, together with Aristotle (*De caelo* 1, chap. 88), a principle and axiom gathered by induction from experiments and well enough known to the senses of itself: *heavy bodies descending by natural motion through a lighter medium move continually faster and faster the nearer they approach the end toward which they tend* — that is, the nearer they approach the centre of the Earth, whether this happens because this centre is the centre of gravity, or because it is the centre of the whole terrestrial element, to which whole all earthly bodies seek to be joined. This increase of speed, plain to the attentive eye itself, has shown itself far more evidently in the much more violent sound and the much more powerful impact that follow when some heavy, hard body is let fall from a higher place rather than from a lower one. Aeschylus, had he survived, could have borne witness to this. An eagle, hovering very high above in lofty flight directly over him, let fall a tortoise it had earlier seized in its talons onto the bald scalp of his head, which it took for a stone; and seeing the tortoise broken, it suddenly swooped down to devour the creature's flesh, like a kernel taken out of its natural shell. For they say Aeschylus died of that blow, which would by no means have happened to him from it, if that body had been let fall from close by. So the tortoise, a brute animal, when it struck and was struck back, broke the shell of a rational soul — a skull holding no ignoble brain — in such a way that, shattered in the wound of the other, who was soon to die, it perished itself. And while it left the corpse of Aeschylus in that field exposed to the crows, as far as lay in it, it went as food — itself the meaner fare, and the slowest of creatures — to the nobler and swiftest of birds. Yet this increase of impetus, inseparably connected with the increase of speed and manifest to the three principal senses, sight, hearing and touch — indeed even to the birds themselves — has not lacked people who dared to call it into doubt, or even flatly to deny it.

[Margin: Five errors concerning the descent of heavy bodies.]

II. In this matter, however, I have found five different errors. [Margin: 1st error.] First, some deny that heavy bodies descending naturally move uniformly difformly, that is, with an unequal but ever greater speed toward the end; and they dare to affirm that these bodies move equally, considering not only their real motion, but also the motion that appears to us to take place along a straight perpendicular line. Among them is Simplicius, on *De caelo* 1, text 88, commentary 86, toward the end, where he calls this into doubt. [Margin: Of Simplicius.] But plainly in this class is our Rodericus Arriaga [Rodrigo de Arriaga], disputation 4 *De generatione*, section 5, subsection 3, affirming that the same mobile, whether it is heavy and moves downward or light and moves upward, always moves with equal speed. [Margin: Of Arriaga.] Niccolò Cabeo, too, on book 1 of the *Meteorologica*, text 17, at the end of question 3, professes himself undecided on this matter, when he said of a descending heavy body: *Nor is this very thing certain to me, whether the speed grows uniformly difformly in equal parts of time and of space, and consequently whether it can make a triangle of*

speed; therefore I can establish nothing certain. [Margin: Of Cabeo.] He is alluding to Galileo's triangle, of which more below.

[Margin: 2nd error.] Secondly, Galileo, in dialogue 2 on the twofold system of the world, Latin page 120, Italian page 159, concedes an apparent inequality in the descent of heavy bodies along a perpendicular line. [Margin: Of Galileo.] But he says that this motion, because of the annual motion of the Earth, in reality takes place along a circular line, and in such a way that equal arcs are traversed in equal times. The author of *Philolaus* too — that is, Boulliau (for in book 1, chap. 7 of the *Astronomia Philolaica* he professes himself the author of that book) — teaches in book 1 of *De vero Mundi Systemate*, chap. 4, that this motion, which appears to us to be in a straight line and irregular, in reality takes place, or is composed, from two circular motions, each of which is equal and uniform, granted that one of them is faster than the other. [Margin: And of Philolaus revived, or of Boulliau.] We shall explain all of this in the next chapter, with figures attached.

[Margin: 3rd error.] Thirdly, some grant that the motion already mentioned is uniformly difform, at least as it appears to take place in a straight line, if any heavy body is considered by itself. But if two heavy bodies of different gravity are let fall from the same height to a ground or floor equally distant, they deny that the heavier moves faster and reaches the floor sooner than the lighter. So Galileo, whose person Salviati bears in dialogue 2 on the two systems of the world, Latin page 164, Italian page 218. [Margin: Of Galileo.] When he wished to investigate the time in which an iron ball would reach the Earth from the concave of the Moon, and Sagredo had said: *Let us take, then, a ball of determinate weight, and indeed that very one whose time of descent from the Moon we wish to measure*, Salviati replies: *That makes no difference at all, for balls that weigh one, ten, a hundred, indeed a thousand pounds will measure those same hundred cubits in exactly the same time*; and he adds that he has certain and firm experiments of this, to be brought out in due time in a treatise or dialogues on motion. Since, then, he wants the calculation he presently sets up from the experiment with a height of a hundred cubits to hold good for investigating the time in which an iron ball would descend from the Moon to the Earth, he certainly holds that if two balls were dropped from the very concave of the Moon, one of one pound, the other of a thousand or any number of pounds, each would traverse that space in the same time and strike the Earth at the same moment — at least if they are of the same material or the same species. This same thing, finally, Giovanni Battista Baliani, patrician of Genoa, affirms in book 1 of his short but very pithy treatise on the natural motion of heavy bodies, solid and liquid. [Margin: Of Baliani.] There he says that when he was serving as prefect of the fortress of Savona he found by repeated experiments *that two cannonballs — either both of iron, or one of stone and the other of lead — let fall by him at exactly the same moment of time through a space of fifty feet, even if one weighed only a single pound and the other fifty, struck the ground in an indivisible moment of time, so that only one blow of the two was perceived by the senses.* He then adds that he used two

bodies of almost the same bulk, one of wax, the other of lead: *I found*, he says, *in the wax one a somewhat longer delay in the descent, yet far below the proportion of the weights. For that wax ball, descending through the given distance of fifty feet, was about one foot from the ground when the lead one touched the plane beneath, the intervening air, unless I am mistaken, resisting appreciably and impeding the motion.* From these and other experiments he admits that he came round to the opinion that perhaps gravity behaves as the agent and the material body as the patient, and therefore that heavy bodies move according to the proportion of gravity to matter; and that where they are borne naturally by perpendicular motion without impediment, they move equally, because where there is more gravity there is equally more matter, or material quantity. But if some resistance is added, the motion is regulated according to the excess of the agent's power over the resistance of the patient, or over the impediments to the motions.

[Margin: Of Cabeo.] Niccolò Cabeo agrees with Baliani, ever since he came to know him at Genoa while he was preaching there, and I could never draw him away from that opinion. So much so that on *Meteorologica* 1, text 17, questions 5 and 6, he most emphatically affirms, from his own often repeated experiments, that if two balls are dropped together from the same height, one of one ounce, the other of ten pounds or of any greater weight — whether both are of lead, or one is of lead and the other of stone or wood — then, provided that the air is still and the lighter one is not of such slight weight that, unable to overcome the resistance of the air or breeze, it floats in the air (as a feather or paper does), both will reach the ground at the same moment, and no appreciable difference can be noted in the fall. From this he infers that the speed of all falling bodies is of itself equal. I do not know from what height he dropped those balls. But this I remember for certain: when we were together at Ferrara in the year 1634 and were dropping stones of different weight, and also wooden balls, from the tower of our church of the Society of JESUS, I placed a bronze basin under one and a wooden board under the other, so as to distinguish better by the difference of sound which reached the ground sooner; and I noticed that the heavier one arrived a little sooner. But because that difference was slight — for the place in the tower from which they were dropped did not exceed 80 feet — he could never be brought to admit that inequality, or any, or a difference in the fall.

[Margin: Of Arriaga.] Finally, Arriaga too, disputation 4 *De generatione*, section 5, subsection 3, and, subscribing to him, Bartholomaeus Mastrius and Bonaventura Bellutus, disputation 3 *De caelo*, question 3, from no. 52 to no. 57, assert that any two heavy bodies whatever, whether of the same or of different species, or bulk, or shape, however great their difference in gravity, descend from the same height in the same time and glide down with a speed equal of itself. The foundation of so great an assertion is Arriaga's experiment, in which he says that he often dropped together from the same table a dry crust of bread of two fingers, the pen with which he was writing, and a huge stone which he could scarcely hold up in his hands, and noticed that they struck the floor

together at the same moment and moved equally fast. From this he exclaims and complains that in so easy a matter none of the philosophers ever confirmed this descent by experience, but that nearly all remained in the faith of their forebears.

[Margin: 4th error.] Fourthly, others asserted that heavier bodies descend sooner and move faster, but affirmed too great a difference in the descent and speed of two bodies that are not equally heavy. For they said that speed is to speed as gravity is to gravity, so that if, of two balls, one is of one pound and the other of ten pounds, and both are dropped together from the same height, the one of ten pounds reaches the ground ten times sooner than the other, or in the same time traverses a space ten times longer. So Aristotle taught. [Margin: Of Aristotle.] For he taught not only in *De caelo* 2, text 46, *that what is greater is borne faster*, but also in texts 77 and 79 *that a small particle of earth, if raised and released, is borne downward, and the greater it is, the faster it mo-* ves; but also in *De caelo* 3, text 27, that as body is to body of the same species, or as gravity is to gravity in two bodies of the same species, so speed is to speed, and space traversed in an equal time to space. Many of the Peripatetics later lent their votes to this.

[Margin: 5th error.] Fifthly and lastly, some have strayed from the truth in establishing the increase of speed of heavy bodies and its proportion, though in different ways. Galileo, in dialogue 2 on the two systems of the world, Latin page 163, Italian page 217, had asserted from his experiments that an increase of this kind takes place according to the odd numbers counted from unity — or, what comes to the same thing, that the spaces traversed by a heavy body in natural descent are to one another as the squares of the times, that is, have to one another the doubled proportion of the proportion that the times in which that passage was made have to one another. So if a heavy body covers one palm in the first interval of time, in two intervals it covers 4, in three 9, in four 16, and so on; and therefore, taking the intervals separately, 1 palm answers to the first, 3 palms to the second, 5 to the third, 7 to the fourth. When, I say, Galileo had asserted this from his experiments, and Gassendi had subscribed to it in his second letter *De motu impresso a motore translato*, Cabeo nevertheless, on *Meteorologica* 1, text 17, question 3, not only calls it into doubt, but says that this increase (if it be granted at all that heavy bodies move with unequal speed, uniformly difformly) more probably takes place in arithmetic progression: so that if in the first interval of time the speed was as 1, in the second it is 2, in the third 3, and so on, according to arithmetic progression. [Margin: Of Cabeo.] Baliani, too, in book 4 on the motion of heavy bodies, page 110, thought this much truer. [Margin: Of Baliani.]

[Margin: Of Chiaramonti.] Scipione Chiaramonti, however, in book 12 of *De Universo*, chap. 28, in order to show that the increase of this speed does not grow without limit, but at length decreases so that the speed becomes equal, says that he divided a line AB, about a perch and a half long, into three equal parts, namely AC, CD and DB. To measure the time he used both a beating

clock and water flowing gently from the small spout of a vessel, always with the same weight. The weight, he says, reached B from A in a time of 514 small parts; from C to B in a time of 451; and from D to B in a time of 320.

Diagram. A vertical line set in the left column beside Chiaramonti's account, divided into three parts by two short cross-ticks; the labels are read off the block.

- A (top end of the line)
- C (upper cross-tick)
- D (lower cross-tick)
- B (bottom end of the line)

Since, then, says Chiaramonti, the time from C to D is equal to the time from D to B (understand: if the weight is dropped now from C, now from D), if you subtract DB, 320, from the time CB, 451, there remains DB, of 131 parts. Again, since the whole time from A to D is as much as from C to B, that is, 451 parts, and AB is 514, if you subtract AD from AB, DB remains, a time of 63. Finally, since the time AC equals the time DB if the weight is dropped from A to C or from D to B, and AC, or DB, is 320, then to run through the equal parts the following times are required in order: for the 1st, AC, a time as 320; for the 2nd, CD, as 131; for the 3rd, DB, a time of 63. But the ratio of 320 to 131 is greater than that of 131 to 63. Therefore the ratio of the increase of speed diminishes as the descent proceeds.

So far I have spoken of the — I do not say opinions, but errors — of others, because their opposite is now, for us and for others who were present as witnesses at our observations (which will be reported shortly), not merely probable but evident and certain. And so we shall proceed not from likely conjectures but from infallible physico-mathematical science, by way of the following experiments, to certain conclusions.

I. Classis Experimentorum pro Leuitate distincta à Grauitate.

First class of experiments, for lightness as distinct from gravity.

[Margin: 1st experiment: of air piercing water so as to tend upward.]

III. Take a glass tube or small pipe AB, as we sketch it in the first figure following, at least three feet long and as straight as possible, closed at one end, A, by continuous glass. Fill it almost wholly with water, leaving only a small space AM, as large as the breadth of the smallest finger, the ear finger. Then close the mouth of the tube with a wooden lid, but smear round the vents with bitumen, or with a cerate made of virgin wax, pitch, and powder of Armenian bole or of flower of red stone, so that no more air can enter, much less water escape even drop by drop. When this is done, turn downward the part of the tube whose top, AM, the enclosed air will now have occupied, setting the tube up perpendicular to the horizon. You will see that the air which at B, the bottom of the tube, had had the form of a cylinder occupying the whole cavity of the tube in breadth, soon rises, and rises in such a way that, narrowing itself,

it stretches out lengthwise; and that the upper surface of that little cylinder, which was flat like a little disc, has now become conoidal, as you see at C — so that, namely, it may more easily pass through the water, and as it were perforate it by that shape, and by narrowing itself give way on all sides to the water tending downward. You will notice moreover that this blunt cone, or rather cone of air, becomes more pointed and narrower in its ascent, and hence that more of the descending water passes between its convexity and the cavity of the glass than before; and that finally, when it has flown up to the top of the water, it restores itself to its former cylindrical shape, if the tube's cavity is such. These points being posited, which are most true and which I have often shown to many people, it follows (philosophizing, however, sincerely and prudently) that although the ascent of the air and the yielding of the water begin at the same moment, yet by nature and causality the air moves upward before the water flows in to fill the place the air vacates. For it is the air that, swelling upward, enters the water and forces it to yield to it, as if a wedge were driven into its middle. Otherwise, if the air tended upward for this reason, that it is thrust out upward by the water tending downward, the water would rather pass wedgewise through the air (just as water falling outside a tube breaks through the air beneath it, and does not surround it and receive it into itself) — and that all the more easily, the less fit the air is, by its rarity, to resist what drives it; or at least the water would blunt from above the swelling with which the air swells upward, and, compressing it from below as with forceps, would constrict its lowest part into a conoidal shape. Now if the air is prior in this motion and behaves actively, it certainly does so by some force moving it upward; and philosophers and non-philosophers alike commonly call this lightness. There is therefore a lightness distinct from gravity, and lightness does not consist in the privation of greater gravity.

[Margin: 2nd experiment.]

IV. But take another experiment, perhaps more evident to you, or try it yourself. Fill the tube already mentioned, or another, DE, in the 2nd figure, almost wholly with water, but pour three or four drops of oil on top, still leaving a very small space for a little portion of air, DL. Then close it well, as above, and with the end D turned downward set it upright, perpendicular to the horizon. You will see the air borne upward very quickly and the oil very slowly, so that the air which was at E, penetrating the oil F, is already at H when the oil is still a little above F; and when the air has reached the top of the tube, D, the oil will not yet have got through half the way. So, while the oil is struggling upward around the middle of the tube, turn the lower part of the tube upward again: at once the air H will fly upward, passing wedgewise through the oil G, and will fly through to K. Sometimes, however, it will pass upward through the oil, perforated in this way, in such a manner that a little portion of air, formed into a small globe I, clings to the oil at its top; and then the oil G will tend upward far faster than it would otherwise in the same position, because it will enjoy a twofold motion: one from its intrinsic lightness, the other of traction, by

which it is drawn by the air I. It is therefore a sign that the air is borne upward by its own lightness; otherwise the water, pressing on the oil G, would more easily compress the air I or scatter it to the sides. Nor can any physical and solid reason be given why that compound of oil and air moves faster than the oil alone. For it cannot be said that the air is thrust upward by the oil G as it descends, as the less heavy by the heavier, since the eye plainly sees the oil G borne continuously upward, and not falling back down intermittently so as to drive the air. Nor can it be said that the water, by descending faster, also expels the oil upward faster, since there is no greater mass of water above the oil than before, and the water would very easily compress the bubble of air I. Nor, finally, can it be said that the compound of G and I is something lighter than an equal quantity of water in the same bulk, and that the water therefore exceeds it in gravity more than it exceeds the oil taken by itself, and therefore seeks to occupy its place sooner. For if there is no lightness, and the little portion of air I has some gravity, then rather a heavier body has been made from it and the oil than the oil alone would be.

[Margin: 3rd experiment.]

V. Finally, make a cylindrical vessel ONPQ whose bottom OP is parallel to the horizon, and set on the bottom a wooden cylinder TOPX — but one such that it floats in water, that is, it is not heavier than water but specifically lighter. Holding a rod SR in your hand, press the cylinder down with it, so that it is not lifted upward while someone else fills the vessel with water. Once the agitation of the water has settled, remove the rod SR: the cylinder will then be carried upward with such impetus that it leaps out above the water, occupying in that leap the space ZNQV, and afterwards, settling back, it will float at rest with no small part of it above the water.

That leap, therefore, is a sign of an impetus produced by an intrinsic lightness. For the water cannot thrust the cylinder further than it needs to in order to occupy the lower place, unless the water itself is first carried upward; and that is against its own gravity, and the water does not usually do it except to fill a vacuum and to succeed into the place of another body moved upward by some other force. Moreover, when the cylinder was on the bottom OP, no part of the water can be found that thrusts it upward. Not the part on the bottom: for I suppose a physically perfect cylinder and a bottom of the vessel exactly flat, so that no sensible part of the water can slip in underneath while the cylinder is held there by force by the hand S, by means of the stick RS. Nor the part of the water NTXQ, equal to the breadth of the cylinder: for if that part weighed, it would rather hold the cylinder down in proportion to its own measure. Nor the parts TO on one side and PX on the other, pressing on the sides of the cylinder. For either they press so that the pressure acts along a line parallel to the horizon, or downward, and so they would hold it in the same position; or upward with an oblique effort — and not even this can they do unless they themselves first tend upward, which, as I said, is against the gravity of water, which naturally tends downward or is at rest, and is never carried

upward except to prevent a vacuum, such as would arise from a body raised upward by another force distinct from the power of the water. And this very motion is held by many to be rather one of traction, exerted by a body tending back. Nor, finally, the parts enclosed between NT or QX and the sides of the vessel: for neither do they actually weigh downward, or not more than the parts enclosed within NTXQ, which are of greater bulk and would prevail by their weight in holding the cylinder down.

But what will the adversaries say if in the bottom of the vessel there were a wide hole Y, narrower than the cylinder, however, and closed, which was opened at the same moment that the hand lifts the rod RS? For the water would certainly flow out downward, and yet that cylindrical wood would tend upward. Let them acknowledge, therefore, some lightness in that wood which, by producing an impetus upward, first by nature moves and drives the water, and is the cause that the water, being a fluid body, yields to it so as to slip into its place, lest a vacuum be given. Let them acknowledge too that the water does not actually exert gravity, but rather that the upper parts of the water are pushed by the wooden cylinder and yield place to it by moving aside to the sides, so as to fill the place of those parts which slip in below into the place of the cylinder.

Diagram. Four numbered experiment figures stand in the left column between the opening lines of § V and the rest of its text.

- Figure 1: a tall stippled tube (water), A at the top, M near the top (the small air space), C at the base of a white bell-shaped bubble of air in the lower half, B at the foot.
- Figure 2: a tube with hatched bands at the top (L) and the foot (F), D at the top, E at the foot; three bell-shaped bodies — K beside the upper white one, G beside the dark middle one (the oil), H beside the lower white one; I stands between the upper and middle ones, with a small round mark [?] just below it.
- Figure 3: a cylindrical vessel N Q / O P, with a block T X (R inside it) on its bottom; a hand S presses a rod down onto the block; a dotted rectangle Z V stands above the rim (the space of the leap); Y marks the foot below the vessel (the hole of the closing question).
- Figure 4: a tall tube, A D at the top, B C at the foot, crossed by dotted lines E F, I K, L M and G H, each with a dot on its right-hand dotted line (and a dot at E).

II. Classis Experimentorum Pro Inæquali motu Grauium in Aere velociùs ac velociùs descendentium, quò plus accedunt ad terminum, ad quem tendunt.

Second class of experiments: for the unequal motion of heavy bodies in the air, descending faster and faster the nearer they come to the end towards which they tend.

[Margin: 1st experiment, from sound and hearing.]

VI. The first experiment is taken from sound. Drop a ball of wood, bone or metal from a height of 10 feet into a basin set beneath it, and attend to the ringing that arises from the impact. Then drop that same ball from a height of 20 feet, or two perches: you will hear a much greater and more widely diffused sound. Next raise the basin to a height of 10 feet and drop the same ball into it from a height of 10 feet: you will hear a ringing like the first. In the second fall, therefore, the ball acquired a greater impetus from falling from a greater height than from the lesser one in the first and third falls; and in the second half of its path downward it acquired more impetus than in the first half. So it moved downward with an unequal velocity, and so unequal that in the second fall it descended faster through the last 10 feet than through the first 10. For it is clear from constant experiments that a faster motion of the moving body follows a greater impetus.

If you want a more homely experiment, pour water into a cup from a vessel two or three finger-breadths away from the cup, and you will hear no noise; raise the vessel to two or three feet, and you will hear a noise from the falling water. Hence those who lived at the Catadupa, or cataracts of the Nile, are said by Cicero in the *Dream of Scipio* to have gone deaf from the crash of the waters rushing down from on high in a headlong fall.

[Margin: 2nd experiment, which can be estimated by touch itself.]

The second is taken from an impact perceptible to touch itself. Put your hand under a playing ball while someone else drops it from a height of 10 feet, and you will experience a very light impact; but if it is dropped from a height of 50 feet or more, you will feel your hand struck, not without some pain. The ball, therefore, acquired a greater impetus from the higher fall. This greater impetus, as I was saying, the wretched Aeschylus felt from the tortoise dropped by an eagle from on high onto his head; and the brute bird itself foresaw it, having no doubt of the outcome to come. Elpenor felt it when he fell from a tower; hence Ovid's well-known comparison in Book 1 of the *Tristia*:

> He who falls on level ground (though even this scarcely happens)
> falls so that he can rise from the earth he has touched; but wretched
> Elpenor, fallen from a high roof, met his king as a tearful shade.

And hence that adage, and the very well-known warning of the Poet:

> ..... They are raised on high that they may fall with a heavier crash.....

Finally, do not those who run down some slope conceive so much impetus that, even if they wish, they cannot afterwards check the course which they could very easily have checked at the beginning?

[Margin: 3rd experiment, from an impact that can be estimated by the eyes.]

VII. The third experiment is taken from the greater impact of bodies falling from a height, an impact that the eyes can estimate. A ball of clay which, dropped from a small height, is not itself broken, or cannot break an eggshell or a nutshell placed perpendicularly beneath it, or raise a weight placed in a wooden balance, or penetrate a palm's depth of water, at length accomplishes all

these things if it is dropped from a higher place: for it breaks and is broken, and it raises that weight. So too a wooden ball, or a playing ball, falling from a low height into a cistern or a large vessel full of water, sinks a few finger-breadths below the water; but if it falls from a very high place, it penetrates many feet below the water, and sometimes right to the bottom. And by countless other experiments of this kind it is made evident that a heavy body falling naturally from a higher place has always acquired a greater and greater impetus at the end of its motion.

[Margin: 4th experiment, from the rebound of a playing ball.]

The fourth is taken from the repercussion and rebound of a playing ball upward. We had a leather ball of this kind, very hard and no larger than the yolk of an egg, so that it would strike the ground at a more acute angle, dropped from a height of 37 feet onto a stone-paved floor, and it rebounded up to 7½ feet; but when it was dropped from a height of 73 feet, it rebounded to 11¼ feet. Another leather ball, however, larger and striking the floor at a more obtuse angle, rebounded to about 6 feet when dropped from a height of 37 feet, and to 7½ feet when dropped from a height of 73 feet. But I seem to myself to be playing, so long as I do not proceed to nobler experiments, which demonstrate most evidently not only the inequality in the motion of heavy bodies, but also that the increase of their speed grows uniformly difformly toward the end of the motion.

[Margin: 5th experiment.]

VIII. The fifth experiment, then, which we made very often, was the measurement of the space that a heavy body covers in natural descent in equal times. I had indeed tried this at Ferrara with Father Cabeo in the year 1634, but from the tower of our church, which does not exceed a hundred feet, and with a pendulum [Perpendiculo] whose exact times in the primum mobile I did not yet know. But when I was at Bologna in the year 1640, and had by then examined pendulums of different lengths by the transits of the fixed stars through mid-heaven, I chose for this experiment the smallest one, which has a length, from the vertex of the motion to the centre of the little ball, of one inch and fifteen hundredths more of an inch of the ancient Roman foot.

[Margin: A pendulum applied to the most precise measurement of times.]

As I showed and set out in Book 2, chap. 21, a single simple vibration of this pendulum is equal to 10 thirds of hourly time of the primum mobile, and six vibrations equal one second most exactly. So a single simple vibration of it is very nearly equal to the time that musicians usually mark by the note of the semiquaver [ſemichromatis], if the choirmaster or conductor regulating the voices raises and lowers his hand in the ordinary way. But because the oscillations, or vibrations, of so short a pendulum are very fast and very frequent, and I judged that not even an error of one should be admitted, we used to begin the count again from one after each ten vibrations, each ten being marked by raising a finger of a hand already closed, so that no confusion or deception should creep into the count before the eye. And we used to pronounce the numbers

below ten very rapidly one after another with a shortened nomenclature, such as these Italian words, but pronounced more briefly, as is commonly done here at Bologna: *Vn, dù, tri, quatr, cinq, sei, sett, ott, nou, dies.* If, as I said, you set musical semiquavers under these, and follow the ordinary measure of the musical beat, you will have a very close specimen of the times that a single simple vibration of this pendulum of ours measures.

We also accustomed others to this way of counting, especially Fathers Francesco Maria Grimaldi and Georgius Cassianus, whose help I used a great deal in the experiment about to be set out. And it is indeed wonderful to tell: when those two and I used such pendulums — they standing on the cornice [coronis] of the Asinelli Tower, I on the floor of the platform below — and each of us separately had noted on a sheet the vibrations in which the heavy body descended from there to the floor, there was never, though the experiments were repeated, a difference between us of a single whole little vibration. I know that some will scarcely believe this, and yet I testify that it was most truly so, and the Fathers of our Society already mentioned will always attest it. So much for the pendulum and the measurement of times.

After this we prepared a very large basket full of clay balls, each of which weighed eight ounces. For measuring the shorter intervals we used the windows of our College; for the higher ones, various towers — not the whole towers, but their windows or small windows: namely the tower of San Francesco, which is 150 Roman feet high, that of San Giacomo, 189 feet, that of San Petronio, 200 feet, and that of San Pietro, 208 feet; but chiefly and most frequently the Asinelli Tower, which is 312 feet high in all, but from the cornice to the base, or parapegma, only 280 feet. Since this tower is most convenient for experiments of this kind, just as if it had been built for this purpose, I wish to set it before the eyes.

[Margin: The height of the towers of Bologna.]

[Margin: Description of the Asinelli Tower.]

IX. In the following diagram, let IBCD be the shaft of the tower, the thicker part, standing on a nearly cubical base VYZX much thicker than the shaft of the tower. From this base rises the parapegma YZH, enclosed by rather broad stone railings [cancellis], so that at least six men can walk safely round the tower on it at once, in a single row, between the railings and the tower. At the top, moreover, the cornice BC projects, enclosed by beaked stone railings, so that from the openings G, Φ, O, as from windows, any man of ordinary stature can look down safely and, letting a plumb line down from there to the floor of the parapegma ID, measure the height GI, as we did more than once; and this, as I said, we found to be 280 ancient Roman feet. The other heights we measured partly with rods, and the whole height also by altimetry, together with Father Grimaldi.

[Margin: The suitability of the Asinelli Tower for these experiments.]

The tower, therefore, has very great advantages for this business. For balls dropped from the windows G, Φ, O fall perpendicularly onto the floor ID,

neither striking the foot of the tower nor falling outside the railings YZ. Next, there is no need to stop anyone from crossing the square laid round its base while the balls are being dropped from the cornice; they can be dropped again and again without danger to anyone. Besides, the tower has certain iron bands around F and T, with iron clasps binding the opposite walls together, which we used as limits for measuring the remaining interval to be covered by the ball when it had reached T or F. The line NH, moreover, stands in for the other towers and heights that we used.

Diagram. A woodcut of the Asinelli Tower, standing in the right column beside the text of § X: a tall square brick shaft with a cupola and weathervane on top, set on a broad base; to its right a vertical measuring line.

- G, Φ, O (crowning parapet; Φ in the central opening, O at the right): the openings from which the balls are dropped
- B (left), C (right): the projecting cornice at the top of the shaft
- Q, R, S (down the right side of the shaft), F (left, low on the shaft), T (low on the shaft): points on the tower; F and T are the iron bands of the text
- I, D (foot of the shaft): the floor of the parapegma
- Y (left), Z (right): the railings of the parapegma on the base
- V (left), X (right): the foot of the base
- N (top), M, L, K, β, H (foot), dots on the vertical line: the line NH, standing for the other towers and heights

X. In the year 1640, then, in the month of May, and at other times afterwards, we sought the height Hβ that would be such that a clay ball of eight ounces, let go to itself, would strike the floor after exactly five vibrations of the pendulum already mentioned, that is, in a time of 50 thirds; and we found it to be 10 Roman feet, the experiment being often repeated. Next we sought the height needed for the descent of another ball of the same species and weight in double the time, that is, in ten vibrations, and we found it to be 40 feet, which the interval KH marks. Climbing higher from here, we sought the height due to a time three times longer, that is, to exactly 15 vibrations, for the descent of such a ball, and we found LH to be 90 feet. So for a time of 20 vibrations we found the height MH to be 160 feet; and for 25 vibrations NH to be 250 feet. Finally, because we could not climb to as great a height as 30 vibrations require, a ball was dropped nevertheless, and often, from the cornice of the Asinelli Tower, namely from G to I, an interval of 280 feet; and it struck the floor when we — I standing at I, and Fathers Grimaldi and Cassianus at G — had counted 26 vibrations, as was clear when we exchanged our sheets with one another.

Now let us imagine the intervals of the line NH transferred to intervals of the line OT, and let the interval traversed by the ball in the first five vibrations, that is, in the first time, be OC: for it will be 10 feet, as much, namely, as βH was. The interval of the second time, OQ, will be equal to KH, 40 feet; the interval of the third time, OR, will be equal to LH, 90 feet; and the interval of the fourth time, OS, will be equal to the space MH, 160 feet. Finally, the whole

interval OT, comprised in the 25 vibrations of the fifth time, will be equal to the whole NH, 250 feet. Note, however, that here we take for T some mark on the face of the tower between S and the floor.

[Margin: The increase of the speed of heavy bodies.]

The ball already mentioned, therefore, descended faster and faster the further it receded from O and the nearer it approached D. Taking the intervals separately, each answering to the measures of equal times, it covered OC, 10 feet, in the first time; CQ, 30 feet, in the second; QR, 50 feet, in the third; RS, 70 feet, in the fourth; and ST, 90 feet, in the fifth; and these numbers added together make 250. This increase is remarkable and worth noting, and it is to be confirmed by the following experiment. For here we are inquiring only whether heavy bodies falling naturally through the air along a straight line perpendicular to the horizon descend uniformly or difformly uniformly, and whether with a decrease or with an increase of speed.

III. Classis Experimentorum pro Proportione Incrementi velocitatis Grauium per Aerem descendentium.

Third class of experiments: for the proportion of the increase of speed of heavy bodies descending through the air.

XI. It is true that in the year 1629, when, with Father Daniele Bartolo [Daniello Bartoli] and Signor Alphonsus Iseus, a distinguished geometer, I first began on another occasion to examine two pendulums of the same length and weight let go together from the same point — whether each would always proceed at an equal pace along its arc — I noticed that the oscillations of one and the same pendulum are all, to sense, equal to one another in time, or synchronous; and afterwards, at Ferrara in the year 1634, I established this very thing most certainly with Father Cabeo. Yet I had not yet understood or learned the proportion of the increase of speed of heavy bodies handed down by Galileo in the second dialogue on the system of the world, and asserted to follow the odd numbers [pariter impares] beginning from unity. Indeed, at that time I had suspected from my cruder experiments that it was continually triple, that is, according to these numbers: 1, 3, 9, 27.

[Margin: The proportion of the increase of speed asserted by Galileo.]

Afterwards, however, when permission was granted me to read those dialogues, which the Sacred Congregation of the Index had prohibited and marked with censures, I found in them, at Italian page 217, Latin page 163, that the increase already mentioned was found by him through experiments to follow the odd numbers [pariter impares] counted from unity, namely as 1, 3, 5, 7, 9, 11, etc. I suspected, however, that some deception lay hidden in his experiments, because in the same second dialogue, Italian page 219, Latin 164, he asserts that an iron ball of a hundred pounds, dropped from a height of a hundred cubits, reached the earth in five seconds of time; whereas my clay ball of 8 ounces descended from a much greater height, namely from GI, 280 feet, which make

187 cubits, in exactly 26 vibrations of my pendulum, which make a time of the primum mobile of 4 seconds and 20 thirds. And I was certain that there had been no sensible error in my counting of the time; and Galileo's error, which lay hidden in a time not adjusted exactly to the time of the primum mobile and the transit of the fixed stars through mid-heaven, I transferred to the intervals covered in the descent of that ball. Moreover, I found it hard to believe that he could have used an iron ball of so great a weight, especially since he had not named the tower from which he had had it dropped. So, full of this suspicion, I began, as I said, already from the year 1640, the measurement of this increase with all precision, hoping that I might find some other proportion, perhaps closer to my own. But in fact I found that the one Galileo had asserted is rather the true one.

[Margin: 1st experiment.]

For from what was said in the preceding experiment, set out in number 10, I recognised that the increase followed the proportion of the feet 10, 30, 50, 70, 90, which is just as if it were expressed in the smallest numbers 1, 3, 5, 7, 9.

[Margin: 2nd experiment.]

But not yet fully satisfied with that, I changed the time and took 6 vibrations of the pendulum, which make one whole second of the primum mobile, and with Father Grimaldi I sought the height due to them, such that a clay ball of eight ounces, let go to itself, would reach the floor; and I found βH, 15 feet. Then at the end of another second, that is, of exactly 12 vibrations, I obtained the height KH, 60 feet; at the end of 18 vibrations, that is, of the third second, it was LH, 135 feet; and at the end of 24 vibrations, that is, of the fourth second, it was MH, 240 feet. But a similar ball traversed the 280 feet in the Asinelli Tower, again and again, in 26 vibrations, that is, in 4 seconds and 20 thirds. For although in the greater distances a foot or two taken beyond or short does not introduce a difference of one whole vibration, I nevertheless found that the number of vibrations already mentioned answered most exactly to the intervals already mentioned.

[Margin: The same proportion confirmed by us.]

Hence by this experiment likewise, separating the intervals due severally to equal times, I was certain that this proportion was kept in the feet 15, 45, 75, 105, which is exactly such as holds between the numbers 1, 3, 5, 7: for as 1 is to 3, so is 15 to 45, etc. I found the same by some other experiments, which I pass over here for brevity's sake and because they are entangled with fractions; a third one, however, I shall set out in the following small table.

[Margin: 3rd experiment.]

So I went with Father Grimaldi to Father Bonaventura Cavalerius [Bonaventura Cavalieri], principal Professor of Mathematics in the University of Bologna and formerly a pupil of Galileo, and told him of the agreement of my experiments with Galileo's, at least as regards this proportion; for, confined to his bed or his chair by gout in the hands and feet together, he could not be present at

them. It is incredible to tell how much he was cheered by this joint testimony of ours.

[Margin: The proportion of the spaces covered by heavy bodies in descent.]

XII. Those not ignorant of geometry now recognise that the spaces covered in equal compounded times by heavy bodies of this kind descending naturally are to one another in the doubled ratio of their times, that is, are to one another as the squares of the compounded times. Galileo gathers this very thing in that second dialogue, on the same page, 217, or 163. For in the first experiment the vibrations were, in order, these: 5, 10, 15, 20, 25, whose square numbers (that is, those produced by multiplying the same number into itself) are 25, 100, 225, 400, 625; and the spaces covered were, in order, 10, 40, 90, 160, 250 feet. Now as 25 is to 100, so is 10 to 40; and as 100 to 225, so 40 to 90; and as 225 to 400, so 90 to 160; and finally as 400 to 625, so 160 to 250. So too in the 2nd experiment the order of the vibrations was 6, 12, 18, 24, 26, whose squares are 36, 144, 324, 576, 676; and the intervals traversed and compounded were, in order, 15, 60, 135, 240, 280 feet. But as 36 is to 144, so is 15 to 60; and as 144 to 324, so 60 to 135; and again as 324 to 576, so 135 to 240; and finally as 576 to 676, so 240 to 280. The spaces already mentioned, therefore, are to one another as the squares of the vibrations, or times.

For ease, however, those equal times can be reduced to the smallest numbers, so that the first time counts as 1, the second as 2, the third as 3, the fourth as 4 and the fifth as 5; and so these squares, 1, 4, 9, 16, 25, can be applied to examine the proportion just stated. In the third experiment, however (which you have set out in the small table about to be shown), there ought to have been 288 feet for the proportion already mentioned to be kept exactly; but we could not conveniently test this except from a height of 280 feet. I wish, then, to gather what we have said so far about so beautiful a proportion, and its foundations, into one small table, and to offer it to the Reader to taste in a brief synopsis.

I add, however, that this proportion was not found by us, as I once hoped, in the weight that a falling ball can raise, granted that it tends toward this proportion. For if a ball falling from a height of one foot raises a weight of one ounce, it will not raise a weight twice as great from a height of 4 feet, or a quarter-pound weight from a height of 9 feet, etc. See below, the 12th class of experiments.

Order of experiments	Simple vibrations of a pendulum 1 15/100 inches high	Time of the primum mobile answering to the vibrations (seconds, thirds)	Square numbers of the vibrations	Spaces covered by a clay ball of 8 ounces at the end of the times (Roman feet)	Spaces covered separately in the single times (Roman feet)	Proportion of the increase of speed of heavy bodies in our air (smallest numbers)

IV. Classis Experimentorum pro Duorum Grauium diuersi ponderis Deseensu [recte: Descensu] Inaequali ex eadem altitudine per Aerem.

IV. Class of experiments: for the unequal descent through the air of two heavy bodies of different weight from the same height.

XIII. This experiment is very deceptive unless it is carried out with great diligence and circumspection, and unless conclusions are drawn from it only after prudent regard to everything that can concur to quicken or retard a motion. For the best comparison of all, and one that would remove every doubt, would be to let go, from the same height and at the same moment of time, two balls of the same size and the same species and yet of different weight: if, that is, out of two balls of clay or of metal — one with a diameter of one palm and weighing one pound, the other with a diameter of two palms and weighing eight pounds — we could so rarefy the one-palm ball that, without any other body entering it, it would become two palms across and still keep its solidity. For then, if the heavier descended faster, it would descend by the force of its greater heaviness alone, and the slowness of the other could not be put down either to a difference of species or to a difference of size, which, because of a blunter and more spread-out figure, would break with more difficulty through the larger body of air beneath it; since in everything else there would be parity, except in heaviness.

Nor, on the other hand, is it useful to drop two cylinders or two prisms of equal breadth but of unequal height and weight, made of the same material; for they waver about their centre of gravity in the air and leave the cause of the faster or slower descent in doubt. But since this cannot be done, Father Grimaldi and I prepared what comes next to it and is the best means among the rest: twelve clay balls of solid clay, each weighing 20 ounces, and another

twelve of clay equal in size to the first but hollow inside, each of ten ounces, and so half as heavy as the first. Then we collected many other balls, differing in species, or in size, or in weight, and set up various comparisons.

In the year 1640 in the month of May, in 1645 in August, in 1648 in October, and most recently in the year 1650, we dropped various pairs from the cornice of the Asinelli Tower, having called together many witnesses from our Society. Though not all of them were always present at the same experiments, those present were, namely, Fathers Stephanus Ghisonus, Camillus Rodengus, Iacobus Maria Pallavicinus, Francesco Maria Grimaldi, Vincentius Maria Grimaldus, Franciscus Zenus [?], Paulus Casatus with his pupils, Franciscus Adurnus and Octavius Rubeus — all distinguished for intelligence, judgement and religious integrity.

[Margin: Witnesses and helpers [?] of the experiment.]

And indeed among them were three or four Masters of Philosophy or Theology who, with Galileo, or with Cabeo and Arriaga, had held that any two heavy bodies whatever, let go together from the same height, however great, descend to the earth in the same physical moment of time. But they at once laid this opinion aside.

[Margin: 1st experiment.]

For the lighter clay ball, that is, the one of 10 ounces, let go from G at the same moment as the other clay ball, of the same size but of 20 ounces, was let go from O, appeared still at F, at least 15 feet distant from the floor I, at the moment when the heavier had struck the same floor at D and had already burst into countless fragments. Even before either of them reached the floor, in fact, the lighter — which, to tell them apart, Father Grimaldi by agreement always let go with his left hand — was already plainly seen, well separated from the heavier, a little below the middle of the tower. And when the time was counted by means of the pendulum, the heavier descended in exactly 23 vibrations, that is, in 3″ 30‴ [?], and the lighter in 26 vibrations, namely in 4″ 20‴ of the primum mobile. This experiment, repeated twelve times, always had the same outcome.

Since, then, the difference of the interval FI was easier to observe and made a greater discrepancy than the difference of time, it seemed advisable, in the descent of the other balls, to attend to the interval still remaining to the ball descending more slowly rather than to the difference of time. What we obtained the following table will show more briefly and more clearly; in it the earlier experiments concern pairs of balls of the same size, the later ones balls of different size.

Order of experiments	Balls of the same size	Weight of the balls: ounces	Weight of the balls: drachms	Ball that was faster	Distance of the slower from the floor already struck by the faster
1	Clay, hollow	10	0	The heavier	15 feet
	Clay, solid	20	0		

Order of experiments	Balls of the same size	Weight of the balls: ounces	Weight of the balls: drachms	Ball that was faster	Distance of the slower from the floor already struck by the faster
2	Clay, hollow	20	0	The heavier	16
	Clay, solid	45	0		
3	Clay	9	0	The heavier	20
	Wood	2	4		
4	Clay	20	0	The heavier	12
	Wax	15	0		
5	Wood	4	6	The heavier	15
	Wax	6	7		
6	Wax	1	5	The heavier	30
	Iron	11	7		

[Margin: The 1st experiment was repeated twelve times, the 2nd twice.]
Second part of the preceding table.

Order	Balls of unequal size	Weight of the balls: ounces	Weight of the balls: drachms	Ball that was faster	Distance etc.
7	Clay	5	0	The heavier	5
	Clay	4	0		
8	Clay	21	4	The heavier	12
	Clay	11	4		
9	Clay	27	3	The heavier	15
	Clay	14	1		
10	Clay	18	7	The heavier	35
	Wax	1	0		
11	Clay	2	0	The heavier	25
	Lead	2	4

	Lead	1	0		
20	Clay	38	0	The clay one	3
	Lead	1	0		
21	Lead	1	0	The heavier	5
	Lead	0	4		

Corollaria ex praecedenti Tabula.

Corollaries from the preceding table.

XIV. I here take it that a thing is heavier in species which, in an equal size naturally proper to it, is of greater weight: as lead is said to be heavier than wax, because if two balls one palm across were weighed, one of lead and the other of wax, the lead one would weigh more pounds, or ounces, or drachms, etc., than the wax one. And that a thing is heavier in the individual which is of greater weight absolutely, whether it is of the same species as the other, or of a different one, in respect of which it is called heavier: as a wax ball of a hundred pounds is called heavier than a lead ball of one ounce. Hence arise five useful combinations.

[Margin: 1st combination: of things equally heavy.]

For some things are found that are equally heavy in species and in the individual, as are two lead spheres of one pound each; and these are naturally of the same size — naturally, for nothing prevents one of them, rarefied supernaturally or preternaturally, from becoming of greater size.

[Margin: 2nd combination: of things equally heavy.]

Others are equally heavy in species but not in the individual, as are two lead balls of which one weighs one pound and the other two. Of these, if they are solid, the one that is heavier in the individual, that is, the two-pound one, is also larger — granted that by supernatural or preternatural condensation it could become equal to the other or smaller. But if one of them is hollow inside, or filled with air or with a lighter body, it can, though lighter in the individual, equal the size of the other.

[Margin: 3rd combination [?]: of things equally [?] heavy.]

Others again are equally heavy in the individual but not in species, such as a lead ball and a wax ball each weighing one pound; and naturally the one that is lighter in species, the wax one, is larger — granted that supernaturally or preternaturally it could be condensed so as not to be larger than the other.

[Margin: 4th combination [?]: of heavier things.]

Again, some things are heavier than others both in species and in the individual, as if a lead ball weighs 10 pounds and a wax ball one pound; and these can be equal to the others in size, or smaller, or larger.

[Margin: 5th combination [?]: of heavier things.]

Some, finally, are heavier in species but lighter in the individual, as a small lead ball of one ounce is heavier than a wax ball of a hundred pounds; and these are

naturally smaller than the others. In this combination, through the correlative term, is contained the combination of what is heavier in the individual but lighter in species. For if lead of one ounce, heavier as regards species, is lighter in the individual than wax of a hundred pounds, then conversely wax of a hundred pounds is heavier in the individual but lighter in species than lead of one ounce. With these things laid down, the corollaries written below follow from the preceding table.

[Margin: 1st corollary.]

First. Two spheres equally heavy in species and in the individual naturally descend equally fast through the same medium — understand always: if they are let go together from the same height; for they are of equal size, and so everything is equal. If, however, one of them, supernaturally or preternaturally, became either larger by rarefaction or smaller by condensation, the smaller would descend faster, because the angle of contact — the interior one, with which it would strike the plane of the air beneath it — would be more acute.

[Margin: 2nd corollary.]

Second. Of two spheres equally heavy in species but not in the individual, the one heavier in the individual naturally descends faster through the air: whether they are of equal size, because one of them is hollow inside, as is clear from experiment 1, repeated twelve times, and from experiment 2; or of different size, as is clear from experiments 7, 8, 9, 13, 14, 15, 16, 21. Among these there are some in which I would believe that the speed did not keep, against the excess of individual heaviness, a proportion like the one that appeared in the others — either because of too great an excess of size, which would make an obtuse angle, or because the balls were not perfectly rounded all over. But it is better to report experiments faithfully than to dress them up by trimming them.

[Margin: 3rd corollary.]

Third. Of two spheres equally heavy in the individual but not in species, the one heavier in species naturally descends faster through the air. This is established by experiment 12. And the reason is that, naturally, the one heavier in species is of smaller size than the other, which is equally heavy with it in the individual; therefore it surpasses that other not only in specific heaviness but also in the sharpness of its figure, or of its angle of contact, which arises from the smallness of the sphere — besides the fact that in our case wood is more porous than lead and, because of the lightness of the air or vapours hidden within its pores, less suited to gravitate.

[Margin: 4th corollary.]

Fourth. Of two spheres of which one is heavier both in species and in the individual, the heavier naturally descends faster through the air: whether it is larger than the other, as appeared in experiment 10; or equal to it, as was established by experiments 3, 4, 5, 6; or even smaller, as we saw in experiment 11.

[Margin: 5th corollary.]

Fifth. Of two spheres of which one is heavier in species but not in the individual, the one heavier in species can (speaking naturally) descend faster through the air; it can also descend equally fast; and it can descend more slowly. An example of the first case we had in experiments 12, 17 and 18; an example of the third case in experiments 19 and 20. For the second and third we have a sufficient argument in comparing experiment 8 with 18. In both, the clay ball was of 11 ounces, the drachms being neglected for the moment. Now the clay ball of 11 ounces, let go with the clay ball of 21 ounces in experiment 8, was so much slower that it was 12 feet from the floor when the clay ball of 21 ounces struck it; whereas the clay ball, likewise of 11 ounces, let go in experiment 18 with a lead ball of about 2 ounces, was slower only by as much as the interval of one foot marks. Therefore, if the clay ball of 21 ounces had been let go with the lead ball of about 2 ounces, it would have left the lead ball behind by an interval of 11 feet, or at least of more than one, and would have turned out faster in descent. Since, then, by an increase of individual heaviness it went from slower to faster, the individual heaviness of the clay could certainly have been increased by so little that it would descend equally fast with the lead. I said *at least of more than one* because I am moved by experiments 19 and 20, in which a small lead ball of one ounce gained more in speed through its smallness than it fell short of the heavier clay ball by reason of weight — although that weight was far greater — so that it was indeed slower than the clay ball, but only very slightly slower. The more perfect roundness of the lead balls, compared with the clay ones, also contributed to this.

[Margin: 6th corollary.]

Sixth. Of two spheres let go together from the same height through the same air, the one that is lighter on every count never naturally descends faster or equally fast; for the other is heavier either in species and in the individual, or in the individual, or in species. Therefore, speaking simply, heavier things descend faster naturally — at least in our air. But it rarely happens that they are of different weight and the defect of individual heaviness is compensated by the sharpness that comes of smallness in size, so that they descend equally fast.

V. Classis Experimentorum pro Inaequali descensu Grauium per Aquam.

V. Class of experiments: for the unequal descent of heavy bodies through water.

XV. Although it is by no means necessary, it is nevertheless very useful — both for the argument now in hand and for the completeness of physical speculations — to explore whether, and in what proportion, the speed of heavy bodies descending naturally through water continually increases.

[Margin: 1st experiment.]

First, then, we used two glass tubes, one of which was 3 1/3 Roman feet high and the other 4 feet and 2 inches. We divided them in two by a mark, filled them with water, set them upright to the perpendicular, and let various small

balls down through them. A lead ball of 4 drachms and 10 grains completed the first half of the first tube in about 5 small vibrations of our smallest pendulum, that is, in 50‴, and the remaining half in two vibrations, that is, in 20‴; so it completed the whole height of the tube in 7 vibrations, or in one second of the primum mobile and 10‴ besides. It was therefore far faster at the end of its motion than at the beginning. A glass ball too, whose weight was 15 grains of wheat, measured out the whole tube in its descent in exactly 2″, that is, in 12 vibrations of the smallest pendulum, but the first half in 8 or 8 1/2 vibrations, and the second in about 4. Finally, a bone ball weighing 2 drachms and 6 grains descended through the whole tube in 10 vibrations, namely 1″ 40‴; through the first half of the tube in 7 vibrations, namely 1″ 10‴; and through the second in 3 vibrations, or 30‴. Altogether, then, heavy bodies of these three species descended much faster at the end of their motion than at the beginning. For the rest, see the following small table; these things will be confirmed further by the small table to be shown at number 17.

Length of the glass tube	Order of experi-ments	Balls let down through the glass tube full of water	Weight: ounces	Weight: drachms	Weight: grains	Time of descent through the first half of the tube	Time of descent through the second half of the tube
	1	Lead	0	4	10	0″ 50‴	0″ 20‴
	2	Lead	0	2	6	1″ 10‴	0″ 30‴
3 1/3 feet	3	Glass	0	0	15	1″ 25‴	0″ 40‴
	4	Glass	0	0	7 1/2	1″ 40‴	0″ 50‴
	5	Bone	0	2	8	1″ 10‴	0″ 30‴
	6	Bone	0	0	10	1″ 30‴	0″ 40‴
	7	Lead	0	4	20	0″ 50‴	0″ 20‴

VI. Class of experiments: for the increase of speed of heavy bodies descending through water.

[Margin: Examination of experiment 1.]

XVI. *First.* From the experiments of the table just preceding one may get wind of the proportion we are investigating; for it comes very close to the one we found in air and explained at numbers 11 and 12 — namely, to the proportion of the spaces with the squares of the times. For in experiment 1 the lead ball completed the first half of the tube in 50‴ and the second in 20‴, and so the whole tube in 70‴. But as space 1 is to one twice as long, that is, to 2, or as the half is to the whole, so, as nearly as can be, is the square of the first time, 50‴, namely 2500, to the square of the whole time, 70‴, namely 4900; for 2500 is a little more than half of 4900.

[Margin: Examination of experiment 2.]

Again, in experiment 2 the lead ball covered the first half in 70‴ and the second in 30‴, so that the whole time of passing through the tube was 100‴. But as 1 to 2, so very nearly is the square of the number 70, 4900, to the square of the number 100, 10,000; for 4900 is a little under 5000, which is half the number 10,000.

[Margin: Examination of experiment 3.]

In experiment 3 the whole time of descent of the larger glass ball was 125‴, and the time of the first half of the space was 85‴ (for we resolved the second into 60 thirds). Now as 1 to 2, so very nearly is the square of the number 85, 7225, to the square of the number 125, 15,625, whose half is 7812 1/2; and 7225 comes close to that number.

[Margin: Examination of experiment 4.]

Now in experiment 4 the time in which the smaller glass ball descended to the bottom of the tube was 150‴, but the time of the first half of the space was 100‴. And as 1 to 2, so very nearly is the square of the number 100, 10,000, to the square of the number 150, 22,500.

[Margin: Examination of experiment 5.]

In experiment 5 the larger bone ball passed through the whole tube in 100‴ and through the first half in 70‴. And as 1 to 2, so is the square of the number 70, 4900, to the square of the number 100, 10,000, very nearly.

[Margin: Examination of experiment 6.]

In experiment 6 the other bone ball ran through the tube in 130‴ and through the first half in 90‴. Now as 1 to 2, so very nearly is the square of the number 90, 8100, to the square of the number 130, 16,900.

[Margin: Examination of experiment 7 and of the rest.]

Let us now examine the experiments made in the longer tube, of 4 1/6 feet, and very nearly the same proportion will be found. For in experiment 7 the time of the first half was 50‴, whose square is 2500, while the time of the whole space was 70‴, whose square is 4900 — that is, very nearly twice as large, just as the whole space is double its half. It is well known, moreover, that to these differences of the squares there answer much smaller differences still in their roots.

When the rest are examined in this way, then, the squares of the two times — of the first time for the half space, and of the whole time for the whole space — are found to have stood very nearly as 1 is to 2, which the following small table sets before the eyes.

Order of experiments	Square of the first time	Its root	Square of the whole time	Its root
1	2500	50‴	4900	70‴
2	4900	70	10000	100
3	7225	85	15625	125
4	10000	100	22500	150
5	4900	70	10000	100

Order of experiments	Square of the first time	Its root	Square of the whole time	Its root
6	8100	90	16900	130
7	2500	50	4900	70
8	6400	80	13225	115
9	84100	290	168100	410
10	90000	300	176400	420

XVII. But to investigate by more certain experiments whether the proportion just mentioned was true and continuous, we used three tubes whose heights kept the order of the squares, so that the first was as 1, the second as 4 and the third as 9: that is, the first was of 18 inches, the second of 72 inches and the third of 162 inches — which is the same as saying that the first was of 1 ½ feet, the second of 6 feet and the third of 13 ½ feet. Thus, if the time of the second space completed were double the time of the first, and the time of the third space, or tube, triple the time of the first tube, each traversed by the same ball let down through these tubes filled with water and set perpendicularly upright, we would be certain of the proportion just mentioned. Moreover, since the tubes were unsuited to balls of larger bulk because of their narrowness, and since, as the water fluctuated in the descent and passed through the narrow space, the balls struck alternately against the sides of the tubes, we used a well whose water was 12 feet deep and a cistern whose water was exactly 3 feet deep. The depth of the water in the cistern was therefore to the depth of the well as 1 to 4, that is, as the square of unity to the square of two. In this way too it would be established for us whether the time of descent through the well water of 12 feet was double the time of descent of the same ball through the cistern water of 3 feet, as it ought to be if the increase of speed went according to the squares of the times. What we obtained will be clear from the selected experiments faithfully set out in the following table.

Order of experiments	Balls let down through water	Weight: drachms	Weight: scrupples	Weight: grains	Time of descent, depth 1 ½ feet	Time of descent, depth 6 feet	Time of descent, depth 13 ½ feet
Through water enclosed in tubes							
1	Ebony	2	0	14	3″ 0‴	6″ 10‴	9″ 20‴
2	Ebony	1	0	10	4″ 20‴	8″ 30‴	12″ 50‴
3	Holm-oak	2	1	6	1″ 10‴	2″ 20‴	4″ 0‴
4	Holm-oak	1	1	0	1″ 20‴	2″ 40‴	4″ 10‴

Order of experiments	Larger balls	Weight: pounds	Weight: ounces	Time of descent, depth 3 feet	Time of descent, depth 12 feet
Through well water					
14	Iron	2	1	0″ 50‴	1″ 40‴
15	Iron	1	0	1″ 10‴	2″ 20‴
16	Ivory	0	3	1″ 40‴	3″ 30‴

XVIII. Of the experiments just mentioned, those that agree exactly with the proportion just mentioned are 8, 11, 14 and 15; for the spaces covered in equal times compounded stood to one another as the squares of the compounded times. Experiments 1, 2, 4, 6, 7, 9, 10, 12 and 16 nevertheless support it very nearly, since they exceed or fall short of the desired measure of time by one or at most two vibrations of the pendulum, that is, by 10‴ or 20‴. The rest exceed it by a little more. We, however, set more store by experiment 14 and 15, because the width of the well, the entirely free descent of the balls and the great force of the iron for overcoming the resistance of the water gave us a more evident observation, and one repeated more often. It therefore seems more certain to us that heavy bodies descending naturally through water also have the same increase of speed that they have in air — provided corrected and selected observations are considered. This is said of bodies whose heaviness in species stands to the heaviness of water as it does in iron and similar bodies, and is greater than the heaviness of ivory.

VII. Classis Experimentorum pro Inaequali Descensu per Aquam Grauium Duorum diuersi ponderis.

VII. Class of experiments: for the unequal descent through water of two heavy bodies of different weight.

XIX. Now from the tables set out at numbers 15, 16 and 17 it is apparent that, of two balls of the same species, the one that was heavier in the individual and greater in bulk than the other always descended more quickly from the same height to the same bottom of the water. For the lead ball of 4 drachms and 10 grains ran through the first tube in 70‴, which the lead ball lighter by almost half, that is, of 2 drachms and 6 grains, completed only in 100‴; and so with the other comparisons in the table of number 15. So too in the table of number 17 you will see that the pairs of balls of the same species, or nearly the

same, always descended in such a way that the heavier descended more quickly. This was so evident in water that several of our people who were present — setting aside even a more exact count of the time, and judging the time of the fall by common esti- mation — discerned with certainty that the lighter ball descended somewhat more slowly. I said *nearly of the same species*, because the ivory and the bone balls were not of the same lowest species; and I did not have two boxwood balls that would descend in water, for boxwood is rarely found that sinks to the bottom of the water unless it is knotty.

But since up to this point we had compared balls of different bulk with one another, we wished to compare balls of the same bulk as well. Since we could not attend to the difference of space — either because of the opacity of the tube, or because their narrowness made it hard to let two balls go together — we used the difference of time, which, because of the slowness of motion through a denser medium, namely through water, was more evidently observable for us. Among the balls of the same bulk we made two pairs of nearly the same species, namely one clay ball solid and the other hollow inside; the rest were of different species. The difference of time, then, was as you see in the small table immediately following.

Time of descent of balls of the same bulk.

Order of experiments	Balls let down through water	Weight: ounces	Weight: drachms	Weight: scruples	Weight: grains	Time of descent	Depth of water, feet
1	Clay	1	0	0	0	2″ 0‴	6
	Boxwood	0	3	1	18	9″ 30‴	
2	Lead	0	4	0	10	1″ 20‴	6
	Holm-oak	0	1	1	0	2″ 40‴	
3	Iron	12	0	0	0	2″ 20‴	12
	Ivory	3	0	0	0	3″ 40‴	
4	Stone	37	0	0	0	3″ 20‴	12
	Stone	12	0	0	0	4″ 0‴	
5	Stone	12	0	0	0	4″ 0‴	12
	Iron	25	0	0	0	1″ 40‴	

The stone balls, moreover, were made of the dust of baked brick bound together, and so were of far greater bulk than all the others.

VIII. Classis experimentorum pro Ascensu Inaequali Leuium per Aquam, seorsim sumptorum.

VIII. Class of experiments: for the unequal ascent of light bodies through water, taken separately.

[Margin: The ascent of air and oil through water.]

XX. At numbers 3 and 4 we have already established positive lightness by experiments taken from air and oil enclosed with water inside glass pipes; and we used the same pipes described there to test the inequality of the ascent of

air and of oil through water. Look, then, at the first and second figures set out at number 5. In the first, the air B reached C, the middle of the pipe, in 30 vibrations of the somewhat larger pendulum, but, ascending from C to A, it completed the remaining half in 24 vibrations.

[Margin: 1st experiment.]

The oil, on the other hand, in the second pipe ascended from F to G, the middle of the pipe, in 14 vibrations, and from G to L in 12 vibrations. The reason why the air, which ought to have been faster, was nevertheless slower than the oil, was this: the air alone, keeping its rarity, rose through the narrow channel of the pipe in such a way that it left only the thinnest of paths around itself for the water succeeding into its place; and since the water had to be thinned out, it needed brief delays of time. The oil F, by contrast, pushed by the air E as it penetrated upward, lost some of its original bulk during the ascent, a part of it adhering to the underside of the air itself and flying upward with the air. Hence it came about that around the oil the path for the water succeeding into its place was looser, and so great a delay was not needed, since the water required almost no thinning. But setting aside these rudiments of experiments begun in pipes that were too narrow, let us come to others that are more certain.

[Margin: 2nd experiment.]

Second, then, we used tubes full of water with heights of 4 or 6 feet; letting various balls lighter than water go from the bottom, and then letting the same balls go upward from the middle of the tube, we always found that light bodies move faster towards the end of their motion. For example, a small glass sphere full of air inside, let go from the middle of the tube, ascended upward through a height of 3 feet in a time of one second and 20‴; let go from the bottom of the tube, it ascended through a height of 6 feet in a time of 2″ and 10‴. But if it moved uniformly, it ought to have completed double the space in double the time, namely in 2″ and 40‴. What I say of this one we found by very many other experiments with various small balls lighter than water. But since the narrowness of the tubes did not allow so convenient an operation, we decided to go back to the well, whose water was 14 feet deep. We therefore let down to its bottom a pole made up of partial shafts fastened together; at its lower end was a cylindrical vessel with a lid that could be tipped open in an instant by a drawing-cord, and enclosed in the vessel itself was a sphere lighter than water, which the weight of the lid held inside the vessel. Then, once the pole had been let into the well until the vessel was at the bottom of the well, and the vibrations of the pendulum had begun to be counted at the same moment as the lid was raised, we counted the time in which the sphere rose from the vessel and the bottom of the well to the surface of the water. The same operation was repeated three times, four times or more, so that I and Father Grimaldi, and the others who were present, might be made more and more certain of the same number of vibrations. Further, 7 feet having been marked on the pole just mentioned, the vessel with the same sphere enclosed in it was let down

to the middle of the well water; and the sphere being freed by the raising of the lid, turned back or tipped up so that it could at once make its way upward, we began at the same moment to count the vibrations of the pendulum, until the sphere burst out at the surface of the water. The more select experiments, and those repeated more often, we shall set out in the following table with the utmost good faith; we do not doubt that it will be borne out for those who are willing to try the same things with equal diligence. The pendulum used to count the times equals 10‴ of the hour with each simple vibration, so that 6 vibrations equal one second of the hour. Note, however, that the wax sphere and the bladder were not exactly round on every side, as the other spheres were.

Species of spheres	Diameter: inches of the Roman foot	Diameter: fraction of an inch	Weight: ounces	Weight: drachms	Weight: scruples	Ascent through 14 Roman feet: vibrations	Ascent through 14 Roman feet: time	Ascent through 7 Roman feet: vibrations	Ascent through 7 Roman feet: time
Beech	3	0	5	0	0	28	4″ 40‴	16	2″ 40‴
Beech	2	1/5	2	6	0	37	6″ 10‴	22	3″ 40‴
Wax	2	1/5	3	0	0	88	14″ 40‴	49	8″ 10‴
Glass full of air	3	0	1	4	0	26	4″ 20‴	15	2″ 30‴
Glass full of air	2	1/5	0	7	0	33	5″ 30‴	19	3″ 10‴
Glass full of air	1	1/2	0	1	2 1/2	38	6″ 20‴	20	3″ 20‴
Bladder	2	0	0	0	0 9/24	30	5″ 0‴	16	2″ 40‴
Glass full of water	3	0	9	1	0				
Glass full of water	2	1/5	3	5	1				

From all these and very many other experiments it is evident to us that light bodies in their natural ascent through water move unequally, in such a way that they move faster and pass through the first half of the space in a longer time than the second. For example, ascending through the first half of the water, that is, the seven-foot depth, the beech sphere tra- versed it in 16 vibrations, and the whole water, twice as high, that is, of 14 feet, in 28 vibrations. It therefore completed the later half in 12 vibrations, when it ought to have taken 16 had it moved evenly; and so with the others. The reason why the wax sphere ascends so slowly is both its lack of the most perfect roundness and the slight difference of specific heaviness between water and wax. For the wax sphere and the glass sphere filled with air each had the same diameter, namely 2 1/5 inches, and the wax sphere weighed 3 ounces, the glass one 7 drachms. We filled that same

glass sphere with water, and its weight was 3 ounces, 5 drachms and one scruple. Taking away, then, the weight of the glass alone, which was about 7 drachms, there remains a weight of water of 2 ounces, 6 drachms and one scruple — but of water whose diameter is smaller by twice the thickness of the glass sphere, which was certainly small. From this we gather that, if a sphere of water were equal to the wax sphere, the water sphere would be slightly heavier. This is also clear from the immersion itself, for the wax floats in water in such a way that, although it does not descend to the bottom, it is nevertheless almost wholly submerged below the surface.

IX. Classis Experimentorum pro Incremento Velocitatis Leuium per Aquam Ascendentium.

IX. Class of experiments: for the increase of speed of light bodies ascending through water.

XXI. From the experiments of the eighth class it is quite clear that the light bodies we used do not increase in their ascent through water in such a way that the spaces covered stand to one another as the squares of the times; rather, the square of the whole time in which 14 feet were traversed is much more than double the square of the time in which 7 feet were traversed. For example, the time in which the larger beech sphere traversed 14 feet was 28 vibrations, whose square is 784; but the time in which the same sphere traversed 7 feet was 16 vibrations, whose square is 256. Yet 784 to 256 is more than as 2 to 1, since it is as 3 to 1 and more. And so you will find with the other times corresponding to the whole space and to the half; you may see the squares of these times in the following small table, in the same order as we kept in the preceding one.

Vibrations	Squares	Vibrations	Squares
28	784	16	256
37	1369	22	484
88	7744	49	2401
26	626	15	225
33	1089	19	361
38	1444	20	400
30	900	16	256

Therefore the proportion that bodies of this kind keep is inconstant. In some, the time of the first equal space seems to be to the time of the second equal space as 4 to 3; in some, as 5 to 4; in some, nearer to equality, as 10 to 9. For in the first experiment 28 vibrations belong to the whole space of 14 feet, but 16 vibrations to its first half; when these are taken from 28, 12 remain. And as 16 is to 12, so is 4 to 3. Likewise, when 22 is taken from 37, 15 remain; and as 22 is to 15, so very nearly is 4 to 3. But it is not so in the other experiments, as you will learn if you subtract the time assigned to the first half from the time of the whole space.

[Margin: Why is the increase of speed less in light bodies than in heavy ones?]

The reason why bodies of this kind do not have so great an increase of speed in water is not heterogeneity alone — as in the glass spheres made up of glass, which is heavier in species than water, and of air; or in the wooden ones, which soak water into their pores the more, the more often the experiment is repeated within a short time. The sole or chief reason is that the excess of the heaviness of water over the heaviness of the bodies just mentioned is far smaller than the excess of the heaviness of a metal or stone sphere over the heaviness of water, or over the slight heaviness of our air. But if bodies were found as much lighter than water as metal or stone bodies are heavier than water — let alone than air — then it is very probable that the increase of speed would go according to the squares of the times. Thus, if a lighter sphere ascended through a space of 7 feet in a time of 5 vibrations, whose square is 25, it would complete a space twice as great in 7 vibrations, whose square, 49, is very nearly double 25.

X. Classis Experimentorum pro Inaequali Ascensu binorum Leuium per Aquam, sed differentis Leuitatis.

X. Class of experiments: for the unequal ascent through water of two light bodies, but of different lightness.

XXII. From the same small table of number 20 it is quite apparent that the bodies which are lighter either in species and in the individual together, or at least in species, ascend more quickly through water. For when three spheres of different species but of the same bulk are compared with one another — namely the smaller beech sphere, the wax sphere and the glass sphere filled with air (so that the inequality may not be put down to shape or bulk) — it is plain that the lightest, namely the glass-and-air sphere of 7 drachms, ascended in 33 vibrations, the beech sphere of 22 drachms in 37 vibrations, and the wax sphere of 24 drachms in 88 vibrations. Again, comparing the larger beech sphere with the larger glass-and-air sphere of the same bulk, that is, of three inches in diameter, the glass-and-air sphere of 12 drachms ascended in 26 vibrations, but the beech sphere of 5 ounces, or 40 drachms, in 28 vibrations. These comparisons are for bodies lighter in species and in the individual together. For bodies lighter in species only, compare the larger beech sphere with the wax sphere. The bladder, for its part, was not perfectly spherical, as we have already noted; moreover, it was soaked through in the water so quickly and took up the moisture so much that, having become heavier, it exceeded the weight assigned to it in the table.

XI. Classis Experimentorum, pro lapsu globorum diuersorum per planum inclinatum ad Horizontem ad diuersos inclinationum gradus.

XI. Class of experiments: for the fall of various balls along a plane inclined to the horizon, at various degrees of inclination.

XXIII. We prepared a wooden tube, or canal, of 35 feet. Raising it from the plane of the horizon, we counted the time in which both water and various balls descended along the whole slope of the canal, and we repeated this at various times in the presence of some Fathers of our Society. We shall represent the experiments in the following diagram and in the table belonging to it. In the diagram, AB is the perpendicular line and AC is parallel to the horizon; above AC, on AB but moved forward towards C, the various heights of the right-hand end of the canal were measured. Further, the angles ACL, ACK, etc. are the angles at which the canal was raised from the horizon; the rest you will learn from the table.

Diagram. A right-angled fan of lines in the right column: a vertical line AB stands at the right, with points marked on it from top to bottom B, L, K, I, H, G, F, E, D, A; from the point C at the lower left straight lines run to each of these points, the lowest lying along the base CA, so that the lines rise at successively steeper angles. The vertical line runs on a little above B. A letter M stands above the upper lines, left of centre; the text does not cite it here.

- C (lower left): the vertex at which the inclined lines meet
- M (above the upper lines, left of centre): label, not cited in the text on this page
- B, L, K, I, H, G, F, E, D (on the vertical line, top to bottom): the heights to which the right-hand end of the canal was raised
- A (foot of the vertical line): the right angle, end of the horizontal CA

Do not be surprised that in this experiment we did not use numbers of feet or of degrees that were always round: because of the length of the wooden canal we needed the steps of a certain stone staircase, on which the other end of the canal rested, and their height varied.

EXPERIMENTA PER CANALEM PEDVM 35.

Experiments with the canal of 35 feet.

Height of the canal	Feet	Inches	An-gle	Angle of elevation	Water: time of fall	Wooden ball: time of fall	Clay ball: time of fall	Line of travel
AD	0	11 ⅕	ACD	1° 32′	15″ 40‴	18″ 0‴	19″ 0‴	CD

AK	8	8 ⅓	ACK	14° 21′	4″ 10‴	4″ 0‴	4″ 10‴	CK
AL	10	0 ⅓	ACL	16° 32′	4″ 0‴	3″ 40‴	3″ 50‴	CL

Height of the canal	Feet	Inches	An-gle	Angle of elevation	Water: time of fall	Wooden ball: time of fall	Clay ball: time of fall	Line of travel
AB	12	6 ⅓	ACB	20° 56′	3″ 50‴	2″ 40‴	3″ 0‴	CB

Do not be surprised that the clay ball, though heavier than the wooden one, was slower. It descended through the canal with more continuous friction, whereas the wooden ball, hopping along by its lightness, was carried further on. Now, if water raised one foot from the horizon runs down 35 feet, or 7 paces, in a time of 15″, then, were it to run down with uniform speed, it would seem to run 28 paces in one minute and 1680 paces in one hour. But from a fall of 5 feet, or one pace, it covered 7 paces in about 6″, and therefore 4200 paces in an hour. Yet because of the great force of the waters, a river whose fall is one pace to the mile usually covers about 2000 paces in an hour, notwithstanding the obliquity and winding of its waters, as we said in Book 2, chapter 13, number 8.

XII. Classis Experimentorum pro Eleuatione maioris & maioris ponderis à Graui naturaliter descendente ex maiori ac maiori Altitudine.

XII. Class of experiments: for the raising of a greater and greater weight by a heavy body descending naturally from a greater and greater height.

[Margin: A balance of a construction suited to this.]

To test this I made a balance whose pans were not hung from the beam, or its arms, but fixed on top of it, so that no cords or little chains should hinder the perpendicular descent of the ball onto the very centre of the pans. The beam itself was supported at its middle by a well-steadied prop with a large foot. Once an exact equilibrium of the pans had been found, a second prop was set under the right pan, to keep it in equilibrium when loaded with any weight placed on it — that is, to hold the beam parallel to the horizon. On the other pan, the left one, I gently placed a scruple at its centre, that is, the twenty-fourth part of an ounce; by its force the right pan was raised to a height of 4 digits measured across, and no more, as I often found by trial. Having chosen this height, I fitted a small bell above the right pan, 4 digits away from it, so that the raised pan would make its rising known by the ring, and its failure to rise by the absence of a ring — to the ears more surely than to the eye. Further, I chose a leather playing ball, quite hard, brought to the weight of one ounce by lead inserted among its stuffing, so that no other kind of ball, in falling and striking the left pan, should either be bruised by the pan or bruise or break it.

With these things prepared, I went to a certain square column having the shape of a parallelogram — we have two such in our Solarium — and placed a weight of two ounces on the right pan. I let the ball fall perpendicularly onto the centre of the left pan along the side of the column, with the help of a gnomon that showed this position, while Father Francesco Maria Grimaldi watched whether the ball fell on the very centre of the pan. In this way, by

experiments repeated many times, I determined what height was required for the ball already mentioned to raise a weight of two ounces; then what height, to raise a weight of three ounces; and finally what height, to raise a weight of four ounces. To raise it, I say, in such a way that from the ring — slight, indeed almost the least possible — on the one hand, and from the absence of a ring, if the height were a little less, on the other, the height required to raise the right pan up to the height of 4 digits was made certain. Now, to raise two ounces a height was required of 2 Roman feet and almost a dodrans [three-quarters of a foot], that is, of almost 33 or 32 inches. For the height held at about this limit: from a height of 31 inches the right pan was not raised as far as striking the bell, though it came very near, while from a height of 34 inches the stroke was already strong, and so on. To raise a weight of 3 ounces a height of 84 inches was required, and for a weight of 4 ounces a height of 116 inches, or a little more, as you see in the following small table.

To raise a weight of (ounces)	Let it fall perpendicularly from a height of (inches of the Roman foot)	Difference
2	32	
		52
3	84	
		32
4	116	

A leather ball of one ounce: to raise the weights written below to a height of exactly 4 digits, it must be let fall from the height written below.

[Margin: 1st Corollary.]

Given this, it is now plain that the higher the place from which a heavy body is let fall, the greater the impetus it acquires. For the ounce ball, which by itself cannot raise the pan loaded with a two-ounce weight, or *dextans* [?], can nevertheless do so if it is let fall from a height of 32 inches, etc.; and it raises a weight of 3 ounces from a height of 84 inches, and a weight of 4 ounces from a height of 116 inches.

[Margin: 2nd Corollary.]

It is clear, further, that it is not improbable that the acquired heaviness, or impetus, which a heavy body descending naturally gains at the end of equal times stands to the impetus gained at the end of the following equal time as space stands to space traversed in times that are equal but taken separately; that is, that it has the proportion which the odd numbers counted from unity have. This would certainly be a most beautiful thing, and most worth knowing, if it could be confirmed by continued experiments. For the leather ball by itself already has a gravitation, or impetus, as 1, that is, of an ounce, since by its force it balances one ounce; and with one scruple added it raises an ounce up to 4 digits. From a height of 32 inches, by itself, it raises a weight of 2 ounces to the same height of 4 digits; it has therefore acquired an impetus of one ounce and one scruple. But if it had had to raise the pan only to the least of sensible

heights, a gain of one ounce, that is, of an ounce's impetus, would have been enough; and for this gain a height of very nearly 30 inches would have been enough. When, however, it descends from a height of 116 inches, which is almost four times the height of 30 inches, the time completed was twice as long as that in which it descends from a height of 30 inches. For it is plain from the earlier experiments of Class 3 that if a heavy body has traversed a space as 1 at the end of the first time, it has traversed a space as 4 at the end of the second equal time; and therefore, arguing conversely, if the first space is to the second as 1 to 4, the first time is equal to the second time taken separately. Now at the end of this second time the ball raised a weight of 4 ounces; it therefore acquired an impetus of a quadrans, that is, of ounc- es 3; but in the second time, taken separately, it acquired an impetus of 2 ounces. Now, if the space traversed in the first time is taken as 1, the space traversed in the second time, taken separately, was as 3.

[Margin: How great is the impetus acquired [?] in the motion of heavy bodies?]

Therefore the impetuses acquired at the end of equal times stand to one another as the spaces traversed in times that are equal, but taken separately. I wish we had been able to establish or examine this proportion by experiments continued to greater heights. But we could not: from a height of 270 inches, which was what was needed for the ball to descend in a time triple the first, it could not be let fall so as to land exactly on the centre of the empty pan again and again, as is required to make an experiment certain; for that is too difficult, and is not done without uncertainty. But what I have suspected from this first trace of the proportion I preferred to share with the reader rather than keep entirely silent.

XIII. Classis Experimentorum pro Perfossione Aquae facta à globo decidente ex maiori & maiori altitudine.

XIII. Class of experiments: for the boring through water made by a ball falling from a greater and greater height.

We used a wooden ball of 2 ounces. Let fall perpendicularly over a bucket of water 7 inches of the Roman foot deep, it did not reach the bottom of the bucket from a distance above the water's surface of less than 7 inches; but from a distance of 7 inches it now reached the bottom with a very slight blow, and from a greater distance with a greater blow. We then had a wooden vessel of two congii [bicongium] filled with so much water that its depth was 14 inches. And yet the same ball did not penetrate that whole depth, nor strike the bottom, except from a height of 10 feet measured from the bottom of the water — but from the surface, 8 feet and 10 inches, that is, 106 inches. This might certainly seem surprising. Perhaps it happens because of the resistance of the deeper water and the agitation already set up in it; or rather because the impetus acquired in the air is diminished more and more until it is overcome,

and the wooden ball flies back upward, since it is lighter than water. Since this return happens at once, it is a sign of a very swift extinction of that impetus — namely by the lightness, which resists more and more by producing an impetus upward, until this overcomes the earlier impetus.

Theoremata selecta ex praemissis Experimentis.

Selected theorems from the experiments set out above.

[Margin: 1st Theorem.]

XXIV. *Lightness does not consist in the privation of greater heaviness, but is a quality positively distinct from heaviness.* This is against Epicurus and Strato, and indeed against Plato as reported by Simplicius on Book 1 of *De caelo*, text 89, comment 87; and against Galileo in his treatise on the things that float on water, p. 22. Aristotle refutes the first of these in the same place: if air or fire were thrust upward by an extrinsic force, by water and earth as heavier bodies, they would not move faster at the end but slower, as happens to every body moved by an external force; and besides, a greater fire would move upward more slowly than a smaller fire. But since these assumptions of Aristotle — about the greater speed of the natural motion of the elements at the end, and of a greater fire than of a smaller — could be denied by someone, we decided to confirm them by experiments with air and oil, which are bodies lighter than water, as is clear from what was said in numbers 20, 21 and 22; and, further, to establish this theorem with physical evidence by new arguments and experiments, as we think was done in numbers 3, 4 and 5. As for Galileo's claim that fiery exhalations rise faster through water than through air — whereas, if they were positively light, they ought to rise faster through air, as being the thinner medium — this arises from the comparison, and from the greater excess that the lightness of fire has over the partial lightness of water than over the lightness of air.

[Margin: 2nd Theorem.]

Heavy bodies descending, and light bodies ascending, by natural motion move with a uniformly difform speed, one that grows greater and greater towards the end of the motion. This is, first, against Arriaga, *De generatione*, disputation 4, section 5, subsection 3, who asserts that this motion is equal even in appearance; and against Simplicius on Book 1 of *De caelo*, text 88, and Cabeo on Book 1 of the *Meteorologica*, text 17, question 3, who doubted its inequality, although it is so commonly asserted. Next, it is against Galileo, in the second dialogue on the two Systems of the World, and Boulliau in his *Philolaus*, Book 1, chapter 4. They grant that the motion of heavy bodies appears unequal to us, as it seems to take place along a straight perpendicular line, but hold that in reality it takes place along one or more circular lines, so that it is equal, although because of the motion of the Earth it appears rectilinear and unequal. But against both views the experiments reported from number 6 to 13 for heavy bodies, and from number 20 for light ones, plainly militate: all of them against

the former opinion, or suspicion; and against the latter, those which rest not on the measurement alone of the unequal space traversed in equal times, but on the greater sound, stroke and raising produced by a greater impetus. For if bodies moved equally, from however great a distance they had begun their motion, they would acquire no greater force by which they could produce a greater sound or stroke.

[Margin: 3rd Theorem.]
